NEW HAVEN TRACTION DEAL—According to a statement made by Vice-President E. G. Buckland, the New York, New Haven & Hartford Railroad is planning a $22,000,000 deal in Rhode Island. The New Haven plans to secure control of the United Traction and Electric Company, which has $8,000,000 capital stock and $9,000,000 of five per cent bonds. Included in the deal is the purchase of $5,000,000 four per cent bonds of the Rhode Island Suburban Railway Company. The United Traction and Electric Company owns all the lines in Providence and Pawtucket and their suburbs. Under the present arrangement the New Haven road has only the right to operate these lines. For this privilege it pays five per cent on the United company's capital stock, or $400,000 a year rental. In keeping with its policy the New Haven road wishes to acquire ownership of these lines. The New Haven plan is to give five per cent guaranteed bonds of the New Haven company and to exchange the bonds on a similar basis.

CHICAGO CITY RAILWAY TO BUY ELECTRICITY FROM COMMONWEALTH EDISON COMPANY—A contract by which the Chicago City Railway Company will abandon its power-producing stations and for the next ten years purchase all of its electric power from the Commonwealth Edison Company is ready for approval by the board of supervising engineers. The supervising engineers have already expressed themselves in favor of the contract, but it will be published and distributed before being approved. The contract will be the largest ever made in Chicago for electricity. At the beginning of the term, according to Samuel Insull, president of the Commonwealth Edison Company, it will cost the railway $800,000 or $900,000 annually, and at the end between $1,300,000 and $1,400,000 each year. At the present the street-car company secures slightly less than three-fourths of its motive power from the same company under a less favorable five-year contract. The street-car company will retain its transforming stations.

AMERICAN TELEPHONE AND TELEGRAPH COMPANY TAKES WESTERN ELECTRIC STOCK—The American Telephone and Telegraph Company has arranged to pay for approximately 30,000 shares of Western Electric Company stock, purchased last January, with its four per cent convertible bonds. The transaction involved an exchange of nearly $7,000,000 of the bonds for the shares of the Western Electric Company. The exchange was made through the Merchants' Loan and Trust Company of Chicago. The terms of the offer made by the American Telephone Company to purchase all or any part of the Western Electric Company's stock not then owned by the former corporation were $250 in bonds or $225 in cash for each share, par value $100, of the latter concern's stock. Nearly $3,000,000 of the stock was deposited and this has been paid for in bonds where the amount of stock deposited included more than four shares. The American Telephone and Telegraph Company now controls approximately $12,000,000 of the Western Electric Company's $15,000,000 capital stock.

PHILADELPHIA RAPID TRANSIT LOAN—All interests of the Union Traction Company, of Philadelphia, Pa., which is leased to the Philadelphia Rapid Transit Company, have agreed upon a plan by which a board of directors satisfactory to all is to be elected at a special meeting of stockholders to be held on October 29, and the $5,000,000 loan of the Rapid Transit company is assured. To take the place of the directors who resigned because they held similar positions on the Rapid Transit company's board of directors, the following stockholders have been selected: William P. Datz, Jacob Disston, G. H. Chestnut, Henry Fernberger and E. M. Story. They will take the places to be vacated by the resignations of P. A. B. Widener, George D. Widener, John B. Parsons, George H. Earle, Jr., and William H. Shelmerdine. Jeremiah J. Sullivan's resignation will not be accepted, it has been mutually agreed, and he will be elected vice-president of the reorganized board. Robert A. Balfour, admitted to be the largest shareholder, is slated for the presidency to succeed Mr. Parsons. It has not been decided whether a secretary will be elected to succeed Charles O. Kruger, second vice-president and general manager of the Rapid Transit Company, but this will probably be done. The Balfour committee has sent out letters to stockholders asking for proxies for the directors named and urging each shareholder to vote for the plan by which the Rapid Transit company can pledge securities owned by the Union Traction Company for the proposed $5,000,000 bond issue.

ELECTRIC LIGHTING.

WOONSOCKET, R. I.—The Woonsocket Electric Machine and Power Company has been granted a right of way by the selectmen for its poles and wires.

MALVERN, IOWA—The Malvern Light, Power and Heating Company has begun preparations for stringing nine miles of wire from here to Tabor to carry current for lighting that town.

UNION, MO.—At a special election W. W. McCurdy was granted an electric light franchise by a vote of 111 to 1. The plant is to be in operation by April 6, 1909, when the Tibbe franchise expires.

AUBURN, N. Y.—The contract for building the new plant for the Auburn Light, Heat and Power Company, to occupy the present site of the old building in North street, has been awarded to Charles S. Keim.

SAN BERNARDINO, CAL.—The county supervisors have sold a franchise for many miles of electric power and lighting lines in the eastern section of the valley to the Home Gas and Electric Company, of Redlands.

SAFFORD, ARIZ.—M. E. Webster, formerly local manager of the Consolidated Telephone, Telegraph and Electric Company, is considering a proposition to give Safford and Thatcher an electric lighting and power system.

TAUNTON, MASS.—At a meeting of the county commissioners it was voted to advertise for a loan of $100,000 for the Fall River & Somerset Bridge. Walter H. Law was instructed to draw plans for the electric plant to operate the bridge.

WILLIAMSON, N. Y.—The town board has entered into a contract with the Sodus Electric Light Company to light the streets of this village with seventy incandescent lights of sixteen candle-power each for five years at a cost of $1,000 a year.

GOUVERNEUR, N. Y.—Alexander B. Clark and C. P. McAllaster, of Oxbow, are interested in a scheme to procure power for electric lighting purposes from Bullhead Lake, about two miles from that village. An engineer has surveyed the route.

HEBER, ARK.—An effort is now being made to establish an electric light plant. A corporation will be organized for the purpose of establishing and operating such a plant under the franchise granted W. H. Horton by the city council several months ago.

PURCELLVILLE, VA.—W. Warrington Evans, of Evans & Evans, Washington, D. C., has puchased the Purcellville Canning Factory building at $6,000, which he will equip as an electrical plant and furnish Purcellville, Round Hill, Hamilton and Bluemont with electricity.

NEW HAVEN, CT.—Plans are being perfected for the supplying of the whole of Yale University, including the dormitories, with electric light and power, derived probably from a new central plant. Estimates of the cost of the work, made some time ago, fix the expense at about $60,000.

WASHBURN, WIS.—The city has returned to the Washburn Electric Light and Power Company the lighting plant which was purchased last November. The city has run the plant for almost a year and found it a losing proposition. The lighting company will resume the conduct of the plant.

LEWISBURG, TENN.—A company, recently organized here, known as the Lewisburg Light and Power Company, has purchased the city electric light plant and will assume charge at once. It will greatly improve the system and service, and will establish, in connection, an ice factory and cold-storage plant.

EDMONDS, WASH.—A $20,000 electric light plant is to be built here by local capital. The first unit, with a capacity of 1,500 lights, will be in operation in sixty days. The Edmonds Electric Light and Power Company has been organized for this purpose, backed by C. Malmo, of Seattle; W. R. Ammon, of Prosser, and A. G. Pike, of Edmonds.

LOCKPORT, N. Y.—A new board of directors was elected at the annual meeting of the Niagara, Lockport & Ontario Power Company as follows: H. H. Westinghouse, George C. Smith, Paul T. Brady and Charles A. Terry, of New York city; William M. Clement and William H. Gratwick, of Buffalo, and H. D. Uptegraff, of Pittsburg, Pa.

NEW YORK, N. Y.—Plans have been filed for a one-story electric light station to be built on Blackwell's Island to supply light to the island institutions under the supervision of the commissioner of charities. It is to have a frontage of thirty-one feet and a depth of fifty-six feet and will be built of Greenwich green stone set in broken bond. It is to cost $5,000, according to the estimate of Raymond F. Almirall, architect for the city.

NATCHEZ, MISS.—Lynn H. Dinkens, the purchaser of the Southern Light and Traction Company local plants, comprising the electric light and gas plants, and six miles of electric street railway, sold by order of the court on account of a writ of ouster, the company having been declared a trust, has transferred the entire holdings to the Louisiana Railway Company. The consideration is said to be $5,000 cash, $40,650 stock, and the assumption of a $335,000 mortgage. The new company is domiciled in New Orleans.

WASHINGTON, D. C.—The Navy Department is planning several important improvements and changes in the navy yards at Boston and Portsmouth. At Boston it is proposed to install new electric generating machinery, which will materially increase the capacity of the power plant. This improvement will cost probably $50,000. This improvement will be in addition to the installation of generating machinery and boilers, which is going on at Boston under contract. Bids for the contemplated work will be advertised for in a short time.

LOUISVILLE, KY.—The so-called Fetter electric lighting franchise, carrying with it the privilege to sell electric light in the heart of the city, has been sold at public auction to George G. Fetter, the only bidder, for $5,515. This ordinance was sold six weeks ago to Hardy Burton for $45,515. Mr. Burton failed to pay his money over in the stated time, claiming that the title to the franchise was not perfect. The board of works decided that the Court of Appeals had definitely decided the franchise valid. The board, therefore, forfeited the $2,000 put up by Mr. Burton.

PENDLETON, ORE.—An electric light company has been organized to furnish light for Hermiston, Echo and Umatilla. Work has been started on two power ditches west of Hermiston. The drainage of water from the government and two private reclamation projects will be utilized to develop 500 horse-power. The water will be turned back into the river so as not to interfere with other projects. J. T. Hinkle, a member of the company, says two plants will be in operation before next summer. Other members of the firm are: O. D. Teal, H. G. and Ross Newport.

TOWER CITY, PA.—The Sterling Electric Light Company is pushing work on its plant located at Williamstown. The brick building, which is 150 feet by 60 feet, is almost completed. The boiler and machinery are being placed and the company hopes to begin operations by January 1. The plant is owner principally by Tower City capitalists. It was located at Williamstown, as the town is central, having the towns of Lykens and Wiconisco on one side, with Tower City, Reinerton, Orwin and Reiner City on the east. The company expects to operate its plant during the day.

NAPA, CAL.—The supervisors of Napa County have advertised for bids for a franchise to conduct a farmers' power line from Napa into Lake County, through the Napa Valley. The bids will be opened on November 11. E. D. N. Lehe, of Woodland, is promoting the system and will bid for the franchise. He proposes to supply power not only for electric lights but for pumping water, churning, and even milking cows. The system has been tried elsewhere in this state and has proven practicable and economical for farms and rural communities. Yountville, Oakville and Rutherford are among the towns above Napa which will be reached by the new system.

SYRACUSE, N. Y.—The stockholders of the Syracuse Lighting Company at their annual meeting elected the following directors: Stephen Peabody, New York; Henry Sullivan, New York; Walton Clark, Philadelphia; Lewis Little, George S. Philler, Philadelphia; W. S. Douthirt, Philadelphia; John J. Cummins, Syracuse; Hendrick S. Holden, Syracuse, and Lewis L. Walters, Syracuse. At a subsequent meeting of the directors these officers were elected; President, John J. Cummins; vice-president, Walton Clark; vice-president, J. C. Delong; secretary, W. F. Douthirt; treasurer, Lewis Lillie. President Cummins stated that only routine business was transacted.

ELECTRIC RAILWAYS.

GRAND FORKS, N. D.—The newly organized street railway company of Grand Forks has let the contract for the laying of steel to P. R. McDonnell, of Duluth.

PHELPS, N. Y.—The Phelps board of trustees at its meeting has voted to extend the franchise of the proposed Geneva, Phelps & Newark Electric Railroad another year.

SUFFERN, N. Y.—The board of trustees of Suffern has granted a franchise to the Rockland Railroad Company. This is the New Jersey corporation that proposes to build a road from Paterson to Suffern.

BOSTON, MASS.—The railroad commission has approved of an issue of $150,000 twenty-year five per cent bonds by the Norfolk & Bristol Street Railway for retiring indebtedness in construction of railway.

ELGIN, ILL.—The Elgin, Woodstock & Lake Geneva Railroad has awarded the contract for the surveying and grading of the roadbed to George H. Painter & Company, Chicago contractors. Work will begin immediately.

LONG BRANCH, N. J.—The Atlantic Coast Electric Railway Company, which operates a trolley line between Pleasure Bay and Asbury Park has been granted a twenty-year franchise to run a line between Pleasure Bay and Monmouth Beach.

LEBANON, PA.—A meeting of those interested in the projected street railway which is to extend from Campbelltown to Bismarck, Cornwall and Schaefferstown was held in Lebanon when a temporary organization was effected and steps taken toward the selection of permanent officers.

BAKERSFIELD, CAL.—Captain Cross, of Los Angeles, has issued orders to resume the survey at the Tejon ranch, in this county for the Los Angeles-San Francisco electric short line. The survey already is made from Los Angeles to Tejon ranch and the right of way through the forest reserve has been granted.

HATTIESBURG, MISS.—Officials of the Hattiesburg Traction Company, which controls the street railway franchise in Hattiesburg, announce that they have perfected arrangements for the financing of the enterprise, involving the placing of $250,000 bonds, and work on the plant will commence December 1.

ATLANTIC CITY, N. J.—In bankruptcy for more than a year, the Atlantic City and Suburban Traction Company, operating a line from the Boardwalk here to Absecon and Somers Point, and one time designated to afford an entrance to the resort for a $20,000,000 electric line from Philadelphia, will be sold under the hammer on October 31.

TERRE HAUTE, IND.—Providing for the protection of stockholders and creditors of the Terre Haute & Merom Traction Company, men interested in the enterprise have organized a new corporation with a capital stock of $50,000. Plans for the reorganization of the company were approved and it was decided to go ahead with the construction of the line from Terre Haute to Merom.

SEATTLE, WASH.—A franchise over twelve miles of the county road to Bothell has been granted by the board of county commissioners to the Seattle, Snohomish & Everett Railroad. The road is to be built within five years. The officers of the company are: President, Clyde C. Chittenden; vice-president, J. R. McLaughlin; secretary, treasurer and general manager, C. W. Kimball. The capital stock is $300,000.

SULLIVAN, ILL.—President Starbuck, of the Decatur, Sullivan & Mattoon Interurban, has returned from New York where he went to secure the funds for building this road, which will extend from Decatur to Mattoon. The route has been surveyed, and the right of way and franchises secured. The proposed route will cover forty-two miles. It is expected it will cost $1,000,000 to build and equip the road.

CAIRO, ILL.—A charter for the Cairo & East St. Louis Railway Company has been filed. The charter provides for the building of an interurban railway between Cairo and East St. Louis. The principal office is to be located in Cairo and the capital stock is named as $100,000 with William P. McKinley, L. E. Fisher, George M. Mattis, W. H. Carnahan and George W. Burton as the incorporators and first board of directors.

ST. PAUL, MINN.—The Twin City Rapid Transit Company announces that it will be ready to connect its St. Paul & Minneapolis lines with Fort Snelling as soon as the new bridge over the Mississippi is completed. This work is scheduled to end about March. The new line, which touches Minnehaha Falls, Fort Snelling and one of the most beautiful stretches of the upper Mississippi, will be featured as the scenic route between the Twin Cities.

GALESBURG, ILL.—The new Galesburg, Aledo and Northwestern interurban line will be built in three sections from Galesburg to Alexis or to Rock Island or to Muscatine, according to plans outlined by the promoters at a meeting held in Galesburg. It is proposed to raise $300,000 and build the first section of the line to Alexis. When this stretch is completed and the line is in operation it is proposed to increase the capital stock and take up the construction of the second section of the road.

SHELBYVILLE, ILL.—Engineer A. M. Fisher, Attorney R. T. Eddy, of this city, and John C. Bitzer, of Tower Hill, are engaged in securing right of way between Shelbyville and Pana for the proposed interurban line of the Mattoon, Shelbyville, Pana & Hillsboro Traction Company, and are meeting with success. Mr. Fisher is authority for the statement that G. Cooper, an Indianapolis traction magnate, has secured the pledge of European capitalists to build the road at once, providing the right of way is secured.

ALBANY, N. Y.—The Public Service Commission, Second District, has authorized the Buffalo, Lockport & Rochester Railway Company to issue $200,000 bonds for the acquisition of cars. The cars are to be purchased by the Buffalo, Lockport & Rochester Rolling Stock Company, which will execute a $200,000 mortgage to secure the bonds. The Rolling Stock Company then proposes to sell the cars to the Buffalo, Lockport & Rochester Railway Company upon its agreement to pay ten equal payments of $20,000 each with five per cent interest.

SEATTLE, WASH.—The transfer of the Seattle & Everett Interurban Street Railway system from Fred E. Sander and associates to the Stone & Webster interests, of Boston, is to be followed by the construction of a complete across-the-state electric interurban system. The southern terminus will be Portland, Ore., and the line will reach Vancouver, British Columbia, on the north. A contract is also to be awarded in the near future to build that section of the road between Tacoma and Olympia. The route from the state capital to the Grays Harbor country has been surveyed and the surveyors are now working south from Aberdeen to Portland.

SYRACUSE, N. Y.—Buffalo and Rochester were connected by trolley for the first time on October 2, and with the opening of regular traffic over the new Buffalo, Lockport & Rochester electric lines in a few weeks it will be possible to go from this city to Buffalo by trolley, by way of the Auburn & Syracuse, Rochester, Syracuse & Eastern and the new road. Upon the completion of the proposed extension of the Rochester & Eastern from Port Byron to this city, a trip with but one change, at Rochester, will be possible between the two cities. At the offices of the Beebe syndicate it is stated that the work of extension from Port Byron here will be begun early in the spring. It will require twenty-five miles of double-tracking and will cost $1,250,000, estimated. The Beebe interests are at present directing all efforts toward the completion of the Fulton & Oswego extension of the Lake Shore & Northern road.

DATES AHEAD.

American Electrochemical Society. Fall meeting, New York city, October 30-31.

Association of Car-Lighting Engineers. First annual meeting, Chicago, Ill., November 18.

National Society for the Promotion of Industrial Education. Annual meeting, Atlanta, Ga., November 19-21.

International Independent Telephone Association. Annual convention, Chicago, Ill., December 1-3.

American Society of Mechanical Engineers. Annual meeting, New York city, December 1-4.

American Roentgen Ray Society. Annual meeting, New York city, December 28-30.

Chicago Electrical Show. Coliseum, Chicago, Ill., January 16-30, 1909.

American Association for the Advancement of Science. Annual meeting, Baltimore, Md., January, 1909.

Northwestern Electrical Association. Annual meeting, Milwaukee, Wis., January, 1909.

PERSONAL MENTION.

GENERAL C. EDWARD MURRAY, treasurer of the Crescent Insulated Wire and Cable Company, visited Chicago recently, calling upon his agents, the Metropolitan Electrical Supply Company.

MR. SHELLMAN B. BROWN, general manager of the Maryland Electric Railways Company (Baltimore & Annapolis Short Line), has resigned, after fifteen years' service as superintendent or general manager of the company.

MR. M. McINTYRE, of Detroit, Mich., has been made operating superintendent of the San Francisco, Vallejo & Napa Valley Railway Company, Napa, Cal.. L. J. Perry, formerly general manager, will continue with the company as its business manager.

MR. E. M. HEDLEY, general superintendent of the Hudson Companies, will sever his connection with the McAdoo Tunnels on November 1. It is believed that he will become associated with the Interborough Rapid Transit Company, of New York City.

MR. ALBERT R. EASTMAN has been appointed general passenger agent of the Utica & Mohawk Valley Railway Company, the Oneida Railway Company and Syracuse Rapid Transit Railway Company. Mr. Eastman has for some time been the express agent of these roads and will continue in this capacity.

MR. B. A. BEHREND, for nearly ten years chief engineer of the Bullock Electric Manufacturing Company and for five years chief engineer of the electrical department of the Allis-Chalmers Company, the designer of the Bullock and Allis-Chalmers electrical machinery, has severed his connection with the Allis-Chalmers interests.

MR. BYRON CLINGERMAN, superintendent of the People's Light, Heat and Power Company, Springfield, Ohio, which has been consolidated with the Home Lighting, Power and Heating Company, also of Springfield, has resigned, and is succeeded by John Cook, superintendent of the Home Company, who will have charge of both plants.

MR. F. H. BETHELL, vice-president of the Bell Telephone Company of Pennsylvania and the Chesapeake & Potomac Telephone Company, who has been seriously ill for the past two months from typhoid fever, has left his summer home at Blue Ridge Summit, Pa., for Atlantic City, N. J. Mr. Bethell will, on or about November 1, leave for an extended European trip.

MR. H. P. JAMES, formerly electrical engineer of the Bryant Electric Company, now occupies the position of sales manager for the new line of push-button specialties recently placed on the market by the Cutler-Hammer Manufacturing Company of Milwaukee. Mr. James is a graduate of the Massachusetts Institute of Technology, where he received degrees in both electrical and mechanical engineering. Previous to his connection with the Bryant Electric Company, he was electrical inspector and engineer for the Associated Factory Mutual Fire Insurance Companies. In his present position with the Cutler-Hammer Manufacturing Company he will have opportunity to turn to practical account the result of his past experience in the inspection, testing and manufacture of electric lighting supplies.

OBITUARY NOTES.

MR. JONAS MEYERS, who was recently appointed superintendent of the Conshohocken Electric Light and Power Company, Conshohocken, Pa., was killed by a fall on October 16. Mr. Meyers was forty-three years of age.

DR. FREDERICK A. C. PERRINE, widely known as an authority on electrical subjects, died at his home on West Seventh street, Plainfield, N. J., October 20, following an illness of several months with Bright's disease. He was born at Freehold, N. J., in 1862 and was graduated from Princeton University, receiving the degree of Bachelor of Science. After devoting a short time to practical engineering he accepted the professorship of electrical engineering in Leland Stanford, Jr., University, which position he resigned to become president of the Stanley Electric Company at Pittsfield, Mass., doing some of the pioneer work in long-distance transmission. For the past few years he had been a consulting engineer, with offices in New York. Dr. Perrine was identified with several electrical organizations and was one of the most prominent members of the American Institute of Electrical Engineers, and he was the author of several technical works. He is survived by his wife, two daughters, Margaret and Anne Perrine, and one son, John. The funeral services were held at his late home on Thursday and the burial was at Freehold.

ELECTRICAL SECURITIES.

What it appeared at first would affect the American market very seriously, in the shape of an embroilment of the foreign powers, has lessened its appearance of disastrous consequence, and there are now assurances that for a time at least there will be no clash in the Balkan situation. The removal of the impending possibility of the dumping of American stocks by foreign holders and the strong condition of the banks here have been factors which have buoyed up the market, and with the end of the week prices began to creep upward, halting though the movement was in fact. When it is recalled that business is still far from normal, it comes as a surprise and should call for general gratification to note that railroads report that the gross earnings for the first week in October were only 3.9 per cent less than for the corresponding week in 1907.

Dividends have been declared upon the following electrical securities: Twin City Rapid Transit Company; regular quarterly dividend of 1¼ per cent on the common stock, payable November 14 to stockholders of record October 24. Milwaukee Railway and Light Company; regular quarterly dividend of 1½ per cent on the preferred stock, payable on October 31. United Electric Company; regular semi-annual dividend of 3½ per cent on the preferred stock, payable November 2. West Penn Railways Company; regular quarterly dividend of 1¼ per cent, payable November 2 to stock of record October 24. Michigan Telephone Company; regular quarterly dividends of 1½ per cent on the preferred stock and 1 per cent on the common stock, the preferred dividend payable February 1, 1909, and the common dividend payable December 1. Havana Electric Railway Company; regular quarterly dividend of $1.50 on the preferred stock, payable November 14 to stock of record October 24. Georgia Railway and Electric Company; regular quarterly dividend of 1¼ per cent on the preferred stock. American District Telegraph Company of New Jersey; regular quarterly dividend of 1 per cent.

ELECTRICAL SECURITIES FOR THE WEEK ENDED OCTOBER 17.

TELEPHONE AND TELEGRAPH.

BOUND BROOK, N. J.—The council has granted a thirty-year franchise to the New York & New Jersey Telephone Company.

SALT LAKE CITY, UTAH—The management of the Utah Independent Telephone Company has accepted the new franchise ordinance passed by the council.

MONTGOMERY, ALA.—At a conference of leading officials of the Southern Bell Telephone Company, held in this city, plans were made for the extension of telephone lines into rural sections.

CROOKSTON, MINN.—The Tri-State Telegraph and Telephone Company has asked the city council of Crookston to grant it a franchise to use the streets and alleys and public places of the city for long-distance and toll service.

KNOXVILLE, TENN.—The East Tennessee Telephone Company on October 1 closed a deal connecting the East Tennessee wires with the Trotter exchanges, giving Trotter direct connection with all parts of the United States by long-distance telephone.

CARLISLE, PA.—The Bloserville Telephone Company has entered into an agreement with the American Union lines at Newville for a term of five years. The officers of the Bloserville Telephone Company are: President, George Barrick; secretary, William Calaman; treasurer, George Robert Fry.

CAMERON, S. C.—The Cameron Telephone Company has been organized with James M. Moss as president and Harvey L. Taylor as secretary and treasurer. All of the capital stock has been subscribed. An order has been placed for the equipment with the Western Electric Company. The following comprise the board of directors: James M. Moss, H. L. Taylor, F. I. Culler, J. J. Gee.

VERMILION, S. D.—The Northwestern Telephone Company has taken over the independent telephone line from Yankton to Elk Point, and from Elk Point out by way of Canton. It has also obtained a ninety-nine-year lease giving it connection with the local independent exchange at Yankton, and now controls all toll service out of Yankton.

HATTIESBURG, MISS.—The Home Telephone Company, of Hattiesburg, is negotiating for the construction of a long-distance line from this city to Seminary, with a view to ultimate extension on to Collins and then to Jackson, Miss. Later a line will be built south to Gulfport, thus giving the independent system control of the Gulf and Ship Island territory. Local systems at points along the line will be absorbed by the larger corporation.

BUTTE, MONT.—The Rocky Mountain Bell Telephone Company has started the construction of several new toll lines west from Butte to Deer Lodge and also to Anaconda. These new lines will furnish additional toll facilities for Anaconda, Deer Lodge, Missoula and the Coeur d'Alenes and Spokane. The construction of additional circuits east to Whitehall and Bozeman will also be started as soon as the necessary construction material is assembled.

NEW HAVEN, CT.—The returns of the Southern New England Telephone Company for the nine months since January 1, 1908, show that the additions to the stations in this state number 3,700. There is now a total of 64,000 stations in the state, the city of New Haven leading with a total of more than 10,000. The total number of exchanges in Connecticut is fifty-four. Since January two new telephone buildings have been opened, one in Danbury and one in Middletown, each with a common battery service.

DES MOINES, IOWA—The Farmers & Merchants' Telephone Company, of Marshalltown, with a capital stock of $250,000, has been granted a charter by the secretary of state. The company is made up of the officers and stockholders of the mutual telephone companies of central Iowa and the plan is to incorporate into one company the lines in Calhoun, Dallas, Hamilton, Story, Greene and other central Iowa counties. The stock issue will be 2,000 shares of preferred stock at $50 a share par value, and 3,000 shares of common stock at $50 a share par value. The new company will include the Mutual exchange in Des Moines, Clyde E. Brenton, of Dallas county, president of the Des Moines concern, being one of the officers of the merger. The organization of the new company means also that the working agreements which have been carried on between the different mutual concerns will be annulled and a new agreement entered into to connect the city and the central section of the state with other portions of Iowa.

NEW INCORPORATIONS.

SACRAMENTO, CAL.—Live Oak & Encinal Light and Power Company. $20,000.

LOS ANGELES, CAL.—Home Gas and Electric Company, Newport Beach. $50,000.

AUSTIN, TEX.—Howe Telephone Company, of Grayson County. $2,500. Incorporators: C. A. Shock, S. D. Donohue, R. S. Daugherty.

PETALUMA, CAL.—Mount Jackson Water and Power Company. $20,000. Incorporators: Thomas C. Mellersh, G. P. Hall and Thomas Mellersh.

TRENTON, N. J.—Middlesex Telephone Company, Monmouth Junction. $10,000. Incorporators: Clarence S. Grover, D. C. Mershon and Andrew Ely.

PORTLAND, ME.—Cairo Railway and Light Company, Portland. To manufacture and sell gas and electricity. $1,000,000. President, G. F. Duncan; treasurer and clerk, Edward Woodman, both of Portland.

MONTPELIER, VT.—Groton Telephone Company. $10,000. Organized for the purpose of maintaining telephone lines in the towns of Groton, Bradford, Topsham, Barnet, Corinth, Newbury, Peacham and Ryegate.

STOCKTON, CAL.—San Joaquin Valley Electric Railway Company, Modesto. $1,000,000. Incorporators: Morris L. Brackett, H. E. Teter, John G. Weir, E. T. Zook and G. E. Weaver. To build and maintain an electric railroad from Stockton to Modesto, a distance of thirty-five miles.

OMAHA, NEB.—Omaha & Southeastern Railway Company. To operate between Omaha and Lincoln. $100,000. Incorporators: Ellery S. McNaul, Dever Sholes, Charles L. Dundey, Nicholas D. Doune, L. Howard Brumbaugh, I. G. Ladd, F. H. Rile, G. E. Moffat and Stephen St. John Malven.

NEW MANUFACTURING COMPANIES.

HARRISBURG, PA.—The Fairmount Electric and Manufacturing Company has been incorporated with a capital of $50,000, with Chester S. Leonard, of Philadelphia, as president.

BOSTON, MASS.—The Moving Sign Company has been incorporated to do an electrical sign business. The capital stock is $50,000, and the officers are: C. B. Battey, president; T. S. McGowne, treasurer, Boston.

ALBANY, N. Y.—The Phone-Hear-Plain Company, of New York, has been incorporated with a capital of $100,000. The directors are Berthold Levi, Henry Raphael and Doun Wood, all of New York city.

CHICAGO, ILL.—The Delta-Star Electric Company has been incorporated with a capital of $1,500 to manufacture and deal in electrical goods and appliances. The incorporators are: Garret V. Weart, James G. Weart and James A. Obermiller.

INDUSTRIAL ITEMS.

THE WESTERN ELECTRIC COMPANY, Chicago, Ill., has published an attractive bulletin, No. 5910-8, devoted to electrical equipment for mines.

THE OHIO BRASS COMPANY, Mansfield, Ohio, in the October issue of its bulletin, devotes considerable space to special information on car equipments.

THE NEBRASKA ELECTRIC COMPANY, Lincoln, Neb., announces that the personnel of the company has undergone a change and will hereafter be officered as follows: President, Paul W. Horbach; vice-president and treasurer, Albert G. Munro; secretary, Carl C. Wilson.

THE STUART-HOWLAND COMPANY has leased the adjoining buildings, Nos. 1, 2 and 3 Winthrop square and 12 to 36 Otis street, and has moved its Boston store and office to that address. This gives the company greatly increased space and as there is about 13,000 feet on each floor, with over 325 feet of street frontage, it is unusually light and admirably suitable for the purpose, and the large floor areas will enable it to handle goods with greater economy. Large expense has been gone to in fitting up for each department and the facilities, it is assured, are now unsurpassed. The company has recently acquired several valuable agencies, has largely increased its stock and reports business recently considerably in advance of last year.

THE PITTSBURGH TRANSFORMER COMPANY, Pittsburg, Pa., announces that Judge Archbold, sitting in the United States Circuit Court for the Western District of Pennsylvania, at Scranton, on October 2, handed down a decision holding in effect that infringement was not shown and denying the complainant's motion for preliminary injunction in the suit of the Westinghouse Electric and Manufacturing Company for infringement of the so-called "Stanley Patent No. 469,809," against the Pittsburgh Transformer Company.

THE MASSACHUSETTS CHEMICAL COMPANY announces that it has moved its New York office from 237 Broadway to the Hudson Terminal Building, 30 Church street. A. G. Cozzens is sales agent, as formerly. At the new address the well-known line of electrical tapes, insulating fabrics and compounds and molded rubber goods will be carried to fill emergency orders. The former telephone number, 3440 Cortlandt, is retained. The offices are on the third floor, just at the bridge connecting the two halves of the building.

THE GENERAL ELECTRIC COMPANY, Schenectady, N. Y., in bulletin No. 4621, illustrates and describes its luminous arc lamp for multiple circuits. The Form 2 lamp is intended principally for use in foundries, machine shops, freight houses, etc., where a large unit is desired, and combines high efficiency with low maintenance cost. The lamp is made for 110 and 220-volt direct-current circuits, the 110-volt being suitable for any line voltage from 100 to 125 and the 220-volt lamp for voltages from 200 to 250. The company has also designed a multiple luminous lamp for use on direct-current power circuits and also for use as a headlight on interurban cars and mining locomotives. The bulletin illustrates and fully describes all of these lamps.

THE CENTRAL ELECTRIC COMPANY, Chicago, Ill., is distributing circulars descriptive of its flexible steel conduit and conductors. It is claimed that this conduit is absolutely flexible and can be installed at much less expense than can a rigid pipe system. The circular also contains illustrations of the Armour stripping tools and their application. Copies will be mailed to those interested. The company is also distributing circulars describing "Galvaduct" interior conduit, calling attention to the various structural details. Complete data are also given on the diameter, threads per inch, weights and prices. By means of a chart a graphic representation is given of the comparative sizes of double-braided wires and "Galvaduct" conduit. Copies of this circular will be mailed upon request.

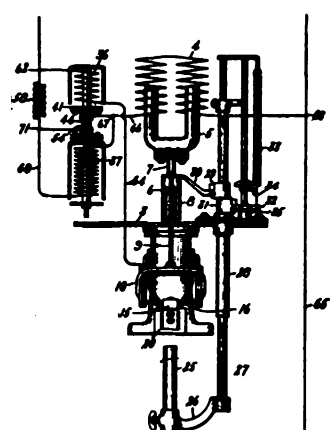
Record of Electrical Patents.

Week of October 23.

900,693. CIRCUIT-BREAKER. Charles C. Badeau, Schenectady, N. Y., assignor to General Electric Company. Filed September 16, 1901. Interoperating toggles are connected in tandem to multiply the force exerted on the movable contact.

900,699. CIRCUIT-CONTROLLER. Alexander Bevan, Providence, R. I. Filed September 16, 1907. Means are provided for absorbing the excess momentum of the circuit-closing lever.

900,708. HIGH-TENSION CIRCUIT-BREAKER. Fred B. Corey, Schenectady, N. Y., assignor to General Electric Company. Filed February 19, 1903. Connected plates of magnetic material are disposed on opposite sides of the contacts.



900,718.—Arc Lamp.

900,718. ARC LAMP. Richard Fleming and Cromwell A. B. Halvorson, Jr., Lynn, Mass., assignors to General Electric Company. Filed May 1, 1905. The movable armature enters the series coil, and the electrode is actuated by differential coils.

900,719. ADJUSTABLE SUPPORT FOR VAPOR LAMPS. Stanwood E. Flitchner, Englewood, N. J., assignor to Cooper Hewitt Electric Company, New York, N. Y. Original application filed July 28, 1904. A combination of a tilting frame and vapor electric lamp.

900,732. ELECTRICALLY HEATED CURLING IRON. Harry Hertzberg and Maurice J. Wohl, New York, N. Y., assignors to Economy Electric Company, Brooklyn, N. Y. Filed April 18, 1907. One of a pair of co-operating members is tubular and contains a resistance therein.

900,733. ELECTRIC LIGHTING. Peter C. Hewitt, New York, N. Y., assignor, by mesne assignments, to Cooper Hewitt Electric Company, New York. Filed April 5, 1900. A combination of tubes, one of which yields a light containing rays which the light from the other tube is deficient in.

900,743. RELAY. Isidor Kitsee, Philadelphia, Pa. Filed October 19, 1907. Means are provided to bring the relaying contacts together independent of the incoming impulses.

900,745. SYSTEM OF ELECTRICAL DISTRIBUTION. Osias O. Kruh, Schenectady, N. Y., assignor to General Electric Company. Filed September 15, 1905. A plurality of rectifiers is engaged in combination with a plurality of energy-storing devices in series across the alternating-current leads.

900,771. ARMATURE FOR UNIPOLAR MACHINES. Jakob E. Noeggerath, Schenectady, N. Y., assignor to General Electric Company. Filed April 25, 1907. The armature has two sets of collector rings and armature conductors between said sets of rings.

900,773. ELECTRIC PLUG RECEPTACLE. George L. Patterson, New York, N. Y., assignor to Alice C. Patterson, New York, N. Y. Filed October 8, 1907. The receptacle has a horizontally hinged closure.

900,777. PREPAYMENT METER. William H. Pratt, Lynn, Mass., assignor to General Electric Company. Filed April 10, 1905. The movable coin chute is held in one position when empty and in another when one or more coins are contained therein.

900,780. DYNAMOELECTRIC MACHINE. Henry G. Reist, Schenectady, N. Y., assignor to General Electric Company. Filed June 20, 1904. In combination with the field poles and windings thereon there is a support for the winding of each pole comprising a portion encircling the pole.

900,781. DYNAMOELECTRIC MACHINE. Henry G. Reist, Schenectady, N. Y., assignor to General Electric Company. Filed March 1, 1905. The collector rings are provided with a cylindrical external contact surface and with a cylindrical internal contact surface.

900,786. TWO-BUTTON SWITCH. Frank W. Sanford, Schenectady, N. Y., assignor to General Electric Company. Filed October 2, 1905. An escape plate is rigidly connected with the contact blade.

900,793. ARC LAMP. George E. Stevens, Lynn, Mass., assignor to General Electric Company. Filed September 27, 1906. The frame is composed of a backbone made of a rod bent into the form of a yoke, having depending legs.

900,830. APPARATUS FOR NEUTRALIZING STATIC ELECTRICITY. William H. Chapman, Portland, Me. Filed January 23, 1908. An electrically charged insulated conductor with small radiating surfaces is secured within a hollow conductor which is connected to earth.

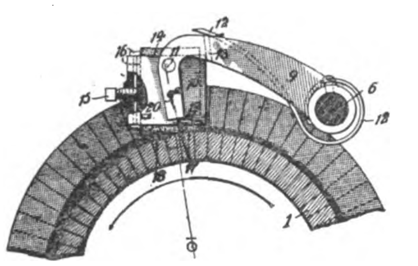
900,854. MEANS FOR LOCKING ELECTRIC SOCKETS TO FIXTURES. Harvey Hubbell, Bridgeport, Ct. Filed March 16, 1907. A coupling device is permanently connected to the socket shell.

900,884. AUTOMATICALLY ADJUSTABLE BRUSH-HOLDER. Walter J. Richards, Milwaukee, Wis., assignor to Allis-Chalmers Company. Filed September 10, 1900. A pivoted brush-holder is arranged with two separate contacting surfaces. The brush is automatically adjustable according to the direction of rotation.

900,898. ELECTRIC ACCUMULATOR. Molière C. Thiellet and Marius J. Denard, Lyon, France. Filed April 3, 1907. An electrode comprising, in combination with the oxide of lead, gelatine gelatinized in aqueous bichromate of potash, and asbestos fibre emulsified in sulphuric acid and silicate of soda.

900,909. ELECTRIC GLOW LAMP, ETC. Fritz Blau and Hermann Remané, Berlin, Germany, assignors to Deutsche Gasglühlicht Aktiengesellschaft (Auergesellschaft), Berlin, Germany. Filed April 25, 1906. A deposit of a metal is provided in the bulb before exhausting the bulb.

900,926. ELECTROLYTIC APPARATUS FOR PURIFYING LIQUIDS. John T. Harris, New York, N. Y. Continuation of application filed June 20, 1903. A magnetized anode of a material which will yield a coagulant, a cathode, and means for separating the impurities from the treated liquid.



900,884.—Automatically Adjustable Brush-Holder.

900,929. PILE PROTECTOR. William Howe, Seattle, Wash. Filed January 28, 1907. An electrode is slidably mounted on the pile and means provided whereby the electrode may be substantially insulated from the surrounding water when submerged.

900,961. PRODUCTION OF MAGNESIUM BY ELECTROLYSIS. George O. Seward and Franz von Kügelgen, Holcombs Rock, Va., assignors to Virginia Laboratory Company, New York, N. Y. Filed October 10, 1905. Magnesium fluoride and calcium chloride are fused together with flux of an alkali fluoride. The bath is rendered anhydrous and then electrolyzed to produce magnesium.

900,962. PRODUCTION OF BARIUM AND BARIUM ALLOYS. George O. Seward and Franz von Kügelgen, Holcombs Rock, Va., assignors to Virginia Laboratory Company, New York, N. Y. Filed March 28, 1906. Fused barium chloride is electrolyzed with the addition of a barium salt of a lower melting point.

900,977. DYNAMOELECTRIC MACHINE. Bernard A. Behrend, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Filed March 26, 1906. The stationary laminated core has circumferential ventilating passageways, and cooling air currents are forced through a hollow frame surrounding said core.

901,013. GALVANOMETER. Louie E. Knott, Boston, Mass., assignor to L. E. Knott Apparatus Company, Boston, Mass. Filed November 24, 1906. A vertically arranged magnet is permanently connected to the base, and a backing plate is detachably secured to the magnet.

901,027. SAFETY GUARD FOR TROLLEY WHEELS. Frank J. Nolan, Buffalo, N. Y., assignor to the Automatic Trolley Guard Company, Buffalo, N. Y. Filed September 13, 1907. Means are provided for supporting the trolley wire in the opening intervening between the two wings of the trolley guard.

901,033. ELECTRIC BELL. George L. Patterson, New York, N. Y., assignor to Alice C. Patterson, New York, N. Y. Filed September 28, 1907. A self-contained wall bell.

901,050. ELECTRIC CLOCK. Charles H. White, Sparrows Point, Md. Filed April 24, 1907. The minute arbor is provided with a tight ratchet wheel and a rocker which is loose on the arbor, having an extended weighted arm and carrying a pawl which engages with the teeth of the ratchet wheel, together with a shank, bearing and armature.

901,108. MUFFLER FOR TELEPHONE TRANSMITTERS. George Kracker, Philadelphia, Pa. Filed December 28, 1907. Sound-deadening material is placed in the mouthpiece and casing.

901,122. SYSTEM OF ELECTRICALLY CONTROLLED SIGNALS FOR RAILWAYS. Jean Paul and Théophile Ducousso, Paris, France. Filed April 13, 1907. Two similar parts are pivotally mounted in a transparent casing and actuated by an energized electromagnet.

901,171. ELECTRIC BURGLAR ALARM. Simon B. Hess, New York, N. Y. Filed May 27, 1907. Multiple alarm signal systems are in shunt with each other.

901,189. MOTOR-CONTROLLING APPARATUS. Michael C. Regan, U. S. Army. Filed February 4, 1908. A step-by-step resistance-inserting mechanism.

901,207. LIGHTNING ARRESTER. Jacob B. Struble, Wilkinsburg, Pa. Filed December 10, 1906. A lightning arrester having in combination means for forming a spark-gap, and means for dampening an arc.

901,212. TELEPHONE HOOK SWITCH. Henry Tideman, Menominee, Mich. Filed July 6, 1907. Locking means are provided for the adjusting screw.

901,213. TELEPHONE HOOK SWITCH. Henry Tideman, Menominee, Mich. Filed July 6, 1907. The tension spring is supported and retained by the locknut.

901,214. TELEPHONE HOOK SWITCH. Henry Tideman, Menominee, Mich. Filed July 6, 1907. The tension spring is adapted to engage and actuate the hook lever.

901,215. TELEPHONE RINGER. Henry Tideman, Menominee, Mich. Filed July 6, 1907. The cores of the electromagnets are drilled and threaded internally at the armature end.

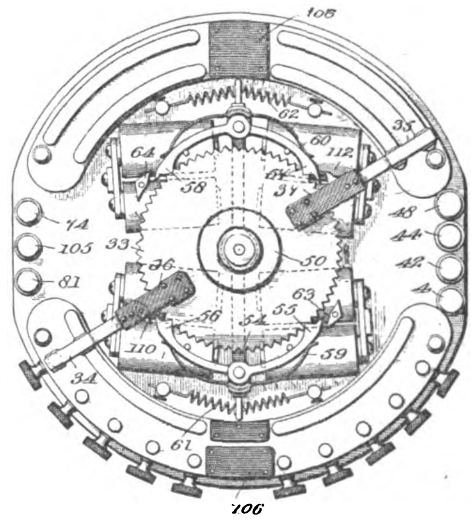
901,216. TELEPHONE RINGER. Henry Tideman, Menominee, Mich. Filed July 6, 1907. The cores and helices of the ringer are mounted within the magnet frame.

901,250. CAB SIGNAL SYSTEM. Daniel J. McCarthy, Wilkinsburg, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Filed May 19, 1908. An indicator is carried by the vehicle and arranged to have a circuit induced therein by current flowing in the track circuit.

901,261. SAFETY FUSE. Frank D. Reynolds and Joseph Sachs, Hartford, Ct., assignors to the Sachs Company, Hartford, Ct. Filed April 17, 1906. The fuse strip has a rupture portion and adjacent portions of substantially the same cross-section as, and of greater heat-radiating surface than, the said rupture portion.

901,269. TELEPHONE RINGER. Henry Tideman, Menominee, Mich. Filed July 6, 1907. The helices and armature are mounted entirely within the U-shaped permanent magnet.

901,280. ELECTROPLATING APPARATUS. John T. Daniels, Newark, N. J., assignor of one-half to the Hanson & Van Winkle Company, Newark, N. J. Filed May 11, 1908. A permeable container is suspended in the stationary tank, and is rotatable on an axis at an angle to the level of the surface of the solution.



901,189.—Motor-Controlling Apparatus.

901,294. APPARATUS FOR ELECTRIC LIGHTING. Peter C. Hewitt, New York, N. Y., assignor, by mesne assignments, to Cooper Hewitt Electric Company, New York. Original application filed April 5, 1900. An incandescent lamp is connected in series with a U-shaped fibre tube.

901,299. METHOD OF PRODUCING ELECTRIC COILS AND CONDUCTORS THEREFOR. Isidor Kitsee, Philadelphia, Pa. Original application filed February 11, 1907. Means are provided for slitting a sheet of conducting material to divide the same into a plurality of strips, and then insulating the strips to adapt same as independent windings.

901,306. SYSTEM OF ELECTRIC DISTRIBUTION. Percy H. Thomas, Pittsburg, Pa., assignor to Cooper Hewitt Electric Company, New York. Filed January 21, 1903. Means are provided for effecting a continuous flow of current in a given direction through a series of vapor rectifiers.

ELECTRICAL REVIEW

THE PIONEER ELECTRICAL WEEKLY OF AMERICA

VOL. LIII. No. 18. NEW YORK, SATURDAY, OCTOBER 31, 1908. ISSUED WEEKLY

NEW YORK
Publishing Office . . . . 13-21 Park Row

ADVERTISING
Changes for advertisements should be in this office by *Friday noon* for the following week's issue.
New Advertisements should be in the office not later than *Monday noon* to assure publication in that week's issue.

Published weekly by the Electrical Review Publishing Company, 13 Park Row, New York. Charles W. Price, president and treasurer; Stephen H. Goddard, vice-president; H. S. Tuthill, secretary.

Entered at the Post Office at New York as second-class matter under the Act of March 3, 1879.

CONTENTS

PUBLISHER'S ANNOUNCEMENT.

The Electrical Review has purchased the *Western Electrician*, of Chicago, and the first issue of the consolidation of these two journals, the Electrical Review and Western Electrician, will be published from Chicago on November 7, 1908.

The Electrical Review was founded by George Worthington in February, 1882, and is the pioneer American electrical weekly. Since its inception consistent effort has been made to promote the development of the electrical industry, and the journal has grown and prospered, until to-day it stands thoroughly entrenched as a technical publication worthy of the interest of discriminating and thoughtful men.

The trend of events to-day is toward the establishment of absolute equities between all the people, and the publisher of a technical journal must lead in the effort to deliver to the purchaser the highest return possible for value received. It is thus with the purpose of better serving its great family of subscribers and advertisers, due to the enlarged opportunities of centralization of effort and the inevitable extension of the industry, that the Electrical Review moves its publication office to Chicago and joins forces with its western contemporary.

There will be no change in the personnel, the present editorial and business organizations of both journals being continued and merged; and the present offices in New York city, supported by a strong editorial and business staff, will be maintained.

ELECTRICAL MACHINERY AND COTTON MANUFACTURERS.

The reciprocity of commerce was admirably illustrated the other day by Dr. E. W. Rice, Jr., vice-president of the General Electric Company, in his sententious address welcoming the National Association of Cotton Manufacturers to the works at Schenectady, when he said that the members of that association had been patrons of the company to the amount of $1,000,000 during the last year, and that the company had purchased cotton cloths and yarns to the same amount during this period.

This also illustrates how both parties can profit at a bargain. It is evident that the electric company sold its goods at a profit and, on the other hand, by the use of electric plant the cotton manufacturers have prospered in the application of a method of lighting which keeps the operatives in better condition, and also makes better goods by the facility of accurate discernment of colors, and the detection of the inevitable imperfections in weaving.

Since the general installation of electricity in textile mills the old-time preference for summer-made goods over those woven in winter, whose shorter days meant artificial lighting, has vanished from the market.

The electrical transmission of power in mill yards is an economic improvement over the use of horses for the purpose. The motor for storehouse elevators has been another element which showed in the insurance rates when the use of a portable steam boiler and engine for the purpose so amplified the premiums that the expensive use of manual labor for hand hoists was indeed the cheaper.

The electric transmission of power is producing the radical change in cotton manufacturing, which has mechanically remained unaltered for nearly a generation. Cotton manufacturing is essentially an engineering problem on account of the relatively low cost of raw material to that of the manufactured product.

Like the proverbial barrel made to fit the bung-hole, the salient problem in cotton manufacturing always has been the transmission of power from the prime mover to the machines. With the progress of the water-wheels, successively of the undershot, breast, overshot and finally the turbines, with their closed trunks in place of the open trench, the positions and dimensions of the mills have been as continuously modified.

The steam engine made other changes, but with all of these the belt tower for power transmission has continued in its costly construction, expensive maintenance and large fire hazard.

Like the doctor in "La Malade Imaginâre," the introduction of electric transmission "has changed all this," and there are quiet intimations of further radical changes in electrical transmission which will force the most astounding changes in the spinning of cotton. The market has no mercy for an old mill, and the iconoclasm of new inventions in converting old machinery into junk is as inexorable as an earthquake.

These are answers to the natural question why the cotton manufacturers should interrupt the natural flow of sessions at their meeting at Saratoga Springs, from a consideration of standard specifications for staple gray goods; what is a plain weave; textile tests in Europe; cones and fliers; colors and dyeing apparatus; textile fabrics and their consumers, and other topics of like ilk, to visit an establishment for the production of electrical apparatus, and the result is that the economic principles of their New England thrift did not permit them to lose the opportunity.

This consideration of electrical questions is no new venture of the Cotton Manufacturers' association. More than twenty-five years ago it began to have papers on electric lighting in mills, and it has continued to have papers on these applications of electricity to this day, keeping to the forefront in giving a fair hearing to those who had anything to offer on the subject which would furnish a contribution toward better results or cheaper processes, and the twain have generally gone hand in hand.

The practical scope of electrical applications is illustrated by the position which this branch of their uses has occupied at these meetings, and this is only one of the many industries where these changes are progressing to the material benefit of all manufacturing interests.

THE RELATION OF ELECTRICAL ENGINEERING TO THE OTHER BRANCHES OF THE PROFESSION.

Electrical engineering, in its various forms, comes into contact with more phases of human activity than does any other branch of the engineering profession, and, indeed, it is called upon oftener by the several other branches to help solve some troublesome problem than is any other division. There is, of course, a reason for this which must depend upon some fundamental principle of electrical engineering and which distinguishes it, in some degree at least, from the other branches and which it will be interesting to elucidate.

This principle should be apparent if we divest any electrical application of all the non-essentials, of all those things which could not be replaced by something else without transferring the application to another branch of engineering. If, in doing so, we find some one feature of these applications which is common to all, it is probable that this feature is one that is largely responsible for the success of the system. When, moreover, we find that this feature is the one which has led to the substitution of the electrical system for various others in different lines of work we are justified in assigning to it the greater part of the credit for the success of all such applications. Is there any fundamental principle in electrical engineering of which this can be said?

Examination of our electric lighting systems shows us a number of new devices, each of which is undoubtedly to some degree responsible for the success of the systems. But do we find any device here which could not be discarded? The dynamo seems to be one, but should another method of producing electrical energy be found, which would be as cheap as the dynamo, the lighting system would still be electrical; and have we not been looking for such a device in the so-called carbon-consuming cell?

Turning to the other end of the lighting system we find no new principle. Light is produced by bringing a body to incandescence through the production of heat. This is the only way we have yet developed; and we have to-day a goodly variety of electric lamps, any one of which could be discarded and its place filled by another. All apparatus coming between the dynamo and the lamp could likewise be discarded, if necessary, except the wires over which the current is transmitted; yet even here we might substitute portable storage batteries by means of which the daily supply of electricity might be delivered in wagons. Since, therefore, no single element of the system can be considered absolutely indispensable, the feature we are seeking must be a resultant of the combination. Now the combination is merely a means of transferring energy from one point to another; in the common phrascology, a means of transmitting and distributing power. In fact, the entire electric lighting system is nothing more than a means for transferring the heat units of the coal to the incandescent element of the lamp.

Do we find the same condition in the electric railway? Obviously the dynamo is no more essential here than it is in electric lighting—very necessary to-day but by no means certain to be a part of the system of the future. The electric motor is indispensable, but does it not merely constitute one step in the more important problem of transferring power from a distant point to the car axles? And is not this transmission of power from a central point to the cars the real explanation of the success of the electric railway? Other systems of accomplishing the same end have been replaced by the electric system merely because the latter has shown itself better in this respect than they.

In the field of general power distribution the same is true, and this system is replacing the local power plant because of the ease and economy with which electrical energy can be distributed from a central point. In the hydroelectric systems it is very evident that the success depends upon this feature. The utilization of water power is not new, but it is only since the development of electrical transmission that we have had a means of transferring the power of the water to a distant point where it can be utilized. The larger water powers represent far more power than a single manufacturing establishment placed on the power site can utilize; moreover, the expense of developing these powers is often greater than the amount of power needed by the factory will warrant. Hence such resources will only be developed when their power can be distributed to a large number of establishments. Electrical transmission offers the only successful means we have of doing this.

Consider a case where this fundamental principle of transmission is less apparent. The telephone seems at first an exception, yet is it not the exception which proves the rule; that is to say, does not a more careful examination of the principles of telephony show that this is only a very special case of electrical transmission and distribution? The power involved is exceedingly small in any single operation, but that does not affect the principle, nor does the fact that this power is not wanted for itself; indeed, we hardly realize that power is being transmitted. But neither do we want the electric power for itself in any of the applications of electricity. What we are after are the results of the transmission of the power: in the one case, light; in another, mechanical power, and in the third a transmission of speech. And what is true of the telephone is true of all electric signaling systems. They are nothing more than special cases of the transmission of electrical energy. We are justified, therefore, in saying that the one common and essential feature of all electrical systems is the transmission of power. The distance of transmission may be a hundred miles or only a few feet, but the principle is the same.

If, then, the principal object of the work of the electrical engineer is the transmission of power, it is clear that he must be a specialist in this work. And to be entirely successful he must specialize on all phases of the problem. Some engineers must devote themselves to the development of the best apparatus for producing and controlling electrical power in the various forms found best adapted to the manifold uses to which this power is put. Others must study the problem of transmitting this power in the most economical and reliable manner. And others, again, must give us the best devices for utilizing the electric power where delivered for producing the desired end. But all may be classed together as specialist in the production and control of power.

If we accept this classification of the electrical engineer as one who deals in the production and distribution of power, the reason for his close association with so many phases of activity is clear. In nearly all of our work power is required and the electrical engineer offers the easiest and most convenient way of obtaining this. Hence he is called in. And the relation of this branch of engineering to the others is also plain. The mechanical engineer produces machines, the electrical engineer furnishes him with the power needed for the production and operation of his machines. The civil engineer builds railroads and various structures and the electrical engineer furnishes him with the power needed in the building and utilization of these structures. He also furnishes the mining engineer with the power the latter needs in his business of producing ores and minerals. And the same relation holds with respect to the other less distinctly recognized divisions of engineering. In fact, we may fairly say that the electrical engineer has appropriated to himself the production of power, just as the other branches have each occupied a different field. This is his domain and here he should rule supreme.

ELECTRIC TUNNELING.

The use of a tiny gas flame or a platinum point heated to incandescence by a circuit has long been used to engrave glass by the decrepitation of small pieces, and this property may be used to a more practicable extent and on a larger scale in rock cutting in tunnels and mining.

A series of electric arcs on a turret at the heading is proposed for the purpose.

The first attempt to pierce Hoosac Mountain in northwestern Massachusetts was by means of a gigantic turret carrying numerous chisels, the invention of General Herman Haupt, but, after boring a hundred feet or so, the machine was abandoned and the 4.71 miles of tunnel made by drilling and blasting.

It was a long time before this tunnel was lighted by electricity, as there was not at the time any insulated wire in the market which would resist the dampness of the tunnel.

THE TEXTILE MILL POWER PLANT.[1]

LEWIS SANDERS, M. E.

The function of a textile mill being the production of goods, its power plant is naturally of secondary importance; also its construction and operation involve a line of management and specialized knowledge that is entirely foreign to the main business of the mill. The power plant, however, is a very serious factor in the profit-earning capacity of the mill, for if every loom and spinning frame is not driven continuously at its maximum economic speed the productive capacity must fall off; there may be a loss of one to five per cent in capacity from this cause; also the cost of power may be excessive.

The power plant has gradually increased in complexity until it has become a distinct branch of engineering beyond the scope of the mill architect proper. Very few mills are developing their power at as low a cost as they should, although they may contain the most economical types of engines and boilers, because these have not been assembled into the most efficient working unit. The power plant has not been sufficiently considered as a working whole, attention having been confined too much to the individual units comprising it. The modern power plant engineer is the product of the electric power industry, where the economical production of power is the life blood of the business, and the shortage of experts in this line may be judged by the number of central stations whose power plants are anything but models, although this matter is of vital importance to them. The introduction of the electric drive now permits the development of the mill and the power plant along the lines suited to each without having the limitations of the one interfere with the other.

The operating management of the mill has to supervise all the processes of manufacture, and on the efficiency of this depends the success of the mill. There is thus on the same management the complex and unrelated business of running a power plant, the result of which can seriously affect the profits of the mill. The management can not give this last sufficient attention without danger of entailing much greater losses in the mill through loss of production. A decrease of mill efficiency of one per cent would offset a power plant economy of twenty per cent. The power plant problem must be met without loading any more burdens on the shoulders of the mill management. Manufacturers specialize in most things except in the production of power. Until recently they had to go into the power business whether they would or not; it will be to the profit of those manufacturers who evolve a proper method of divorcing the power business from the textile industry.

In some cases the problem can be best met by purchasing power, but the central station managers are very much at fault in this matter, as they are rarely willing to make equitable rates. They are running a lighting business first and a power business second. In a few years we will find power the main business and light a by-product. Where power can not be purchased I suggest the formation of what would be practically a separate power plant company from which the mill would take its power and steam exactly as it would from a central station. The larger mills could carry this out independently while the smaller ones could have such an organization in common, the fact that they were competitors being no more bar to this than it would be to their taking power from the same water power company.

In considering the replacement of an existing plant by a more economical one, the economies should be sufficient to pay all fixed charges on the new investment and a satisfactory profit besides, or the change will not be justified.

In considering the change of an existing mill from belt to electric drive it will be found that the saving in power will rarely justify the change, but if the opportunity be taken to completely remodel the power plant the results will frequently justify the investment. Also the possible increase in mill output, due to bringing all machines up to maximum speed, will very often justify the change independently of any power plant economies. In making improvements in a mill it is important that they form part of a comprehensive scheme and not be made in a disconnected manner.

My firm made a test of a large mill of which a small portion was electric driven and the rest belt driven. We found losses of $26,000 that could have been avoided:

Loss due to excessive price paid for coal	$14,000
Loss due to excessive air used in combustion	2,573
Loss due leaky dampers on economizers	1,595
Loss due use of smoke consumers	1,710
Loss due leak in feed-water heater	1,110
Loss due steam wasted by turbine	5,500
Total	$26,488

Aside from the price paid for coal this plant was being run up to the average of good mill practice and in some respects better. The losses found might have existed in the most modern plant if not detected by a most rigid system of records.

The unit costs of operation for the three power plants of this mill, figured on the basis of perfect operation, are:

COMPARATIVE UNIT COSTS OF OPERATION.

(Pocahontas coal, at $4 per ton.)

COST OF COAL, AS BURNED, INCLUDING ALL LABOR.

A plant	$4.50 per ton
B plant	4.72 "
C plant	4.55 "

COST PER 1,000 POUNDS OF STEAM GENERATED.

A plant	20.00 cents
B plant	22.60 "
C plant	23.20 "

COST PER 1,000 POUNDS OF STEAM AVAILABLE FOR POWER, MANUFACTURING AND HEATING.

A plant	25.9 cents
B plant	25.2 "
C plant	25.85 "

COST PER 1,000 INDICATED HORSE-POWER HOURS FOR POWER.

A plant	$2.30
B plant	4.40
C plant	4.27

The differences in costs are, therefore, due entirely to the design of the plants and are a true measure of their relative value. It is interesting to note that the plant that generates steam at the least cost is not the one that supplies it to the mill at the lowest cost.

Steam distribution per week, present plant, is:—

	Pounds.	Per Cent.
Auxiliaries, stokers, etc	1,733,500	14.7
Engines	4,775,100	40.4
Manufacturing purposes	4,426,000	37.5
Heating (mean) for year	875,000	7.4
Total	11,819,600	

Exhaust from one engine used for heating water, part of which is used for manufacturing purposes.

POWER DISTRIBUTION PER WEEK.

No. Hours Run.	Kilowatts per Hour.	Kilowatts per Week.
6	2,430	14,550
55	2,200	110,000
6	200	1,200
67.5	344	22,400
Total kilowatt-hours per week		147,950

NOTE.—The output of the A and B engines has been reduced to equivalent kilowatts.

ANNUAL OPERATING EXPENSE, PRESENT PLANT.

Coal, 27,200 tons, at $4 per ton	$108,800
Labor, power plants	21,723
Labor, filter plants and arc machines	1,130
Removing ashes	953
Total	$132,506

On account of the subdivision of the power plants and the large quantities of live steam used in this mill we found that a new plant could be designed that would show sufficient economies to justify scrapping the present one. The new plant recommended consists of three Curtis vertical turbo-generators of 750 kilowatts capacity each, with special provisions for extracting steam at forty-five pounds for centring and carbonizing, and at five pounds for dye kettles, scouring, heating, etc.; the boilers to be three 1,000-horse-

[1] Paper read before the National Association of Cotton Manufacturers, Saratoga Springs, N. Y., September 29-30. Abridged.

power water-tube boilers, hand-fired with combined forced and induced draft, so as to give the greatest adaptability to various grades of coal.

The size of the unit adopted for turbines and boilers is as large as possible consistent with having the units of such size that if one breaks down the remainder can carry the extra load on overload capacity. The size of unit must also be selected with reference to the load at various times, so that those in operation shall carry as nearly as possible full load, in order to secure maximum economy.

Those more used to belt-driven mills where large engines are correct practice, because provision can not be made for breakdowns, or the load concentrated on one unit, have contended that two 1,500-kilowatt units would be more economical in this case. Not only would these entail a larger investment, but they would be actually more expensive to operate than the smaller units, owing to their poorer load-factor.

As for the effect of substituting steam at five pounds pressure for live steam in the dye kettles, etc., it should be borne in mind that after having done work in the turbine down to this pressure, it still has about 90 per cent of its original heat left, although it has given up nearly 50 per cent of its available energy. To keep up the capacity of the dye kettles, therefore requires only ten per cent greater weight of exhaust steam than of live steam, and large enough pipes to take care of the greater volume at this low pressure.

The new plant consisting of three boilers and three turbines and auxiliary apparatus, will do the work now done by three power plants containing 23 boilers, 4 engines, 1 turbine and the auxiliary apparatus in triplicate. It will require 15 men for its operation as against 33 with the present plant.

STEAM AND POWER DEMANDS, NEW PLANT.

Hours per Week.	Kilowatts per Hour.	Pounds Steam at 45 Pounds.	Pounds Steam at 5 Pounds.	Steam Turbines	Fed to Boiler.	Total Pounds per Week.
6	2,430	9,000	61,500	102,800	108,200	649,000
55	2,200	9,000	61,500	98,200	103,400	5,570,000
6	200	9,000	61,500	80,250	84,400	506,500
15	344	.....	29,000	34,200	36,000	539,000
52.5	344	.....	9,000	14,600	15,400	807,000
33.5	....	.....	9,000	......	10,520	342,000
Total						8,413,500

UNIT COSTS OF NEW PLANT, WITH SOFT COAL, AT $4 PER TON, HAND-FIRED.

Cost per ton of coal burned	$4.42
Cost per 1,000 pounds generated	19.7 cents
Cost per 1,000 pounds steam available to mill.	20.8 "
Cost per 1,000 indicated horse-power	$1.98

ANNUAL COST OF NEW PLANT, USING SOFT COAL, HAND-FIRED, AT $4 PER TON.

18,740 tons of coal	$75,000
Labor	10,250
Removing ashes	610
Total	$85,860

Using the same grade of coal in each case the present plant costs $132,000 per year to operate while the new one will cost only $85,000 a year, or a saving in operating expenses of some $47,000.

A mill load is practically uniform, which is very favorable to economical operation and should permit power to be generated at a lower cost than a central station of the same size, except where the station has built up a heavy day load. But how many mills are able to show any such results? In order to reach high economy a proper system of records is necessary; those kept by most plants are useless. The power plant records to be of value must completely account for everything, practically continuous test data; what is more they must be promptly worked up and acted upon. If they are simply filed for future reference they are a useless expense and had better be omitted.

A separate power plant organization, such as I have advocated, should maintain an experimental station at the most convenient mill, a school of instruction should also be maintained for firemen and engineers. All men should be promoted according to their records, which should always be open to their inspection. Mr. Jurgensen, chief engineer of the Hotel St. Regis, has very successfully organized and conducted such a school for several years, resulting in a higher grade of men and a decrease in operating expenses. Very few mills are aware of what they might save as they do not know the extent of the losses.

My conclusions are that in textile mill power plants we should give more attention to the need of a higher grade of engineering skill and a more careful study of the local conditions in the design of the power plant.

Careful attention to the fact that what is wanted is the power plant that will deliver steam and power to the mill at the least cost and that it is not always the plant showing the highest evaporation or the lowest steam consumption that does this.

The selection of a size of unit, where other conditions do not outweigh it, that will permit one to be thrown out of service and allow the extra load to be carried on the overload capacity of the remaining apparatus.

Not to make improvements to existing mills until a comprehensive plan has been worked out, and then to make all changes in accordance with this.

The advisability of divorcing, where practicable, the power business from the textile industry.

The need of a system of power-plant records that will detect all defects and falling off in efficiency of machinery or men, coupled with a management that will at once remedy them.

Lake Superior Power Company Reorganization.

Announcement is made by the Lake Superior Power Company first mortgage bondholders' committee, which recently advised bondholders to deposit, that considerably more than a majority of the bonds have been deposited, and that an additional number has been pledged. The bonds continue to be freely deposited, many who were awaiting the deposit of a majority now lending their aid to the plan of reorganization.

The committee controls the situation and is said to be engaged in the preparation of a plan of reorganization which will give substantial value to the bonds deposited. The time for deposit has been limited to November 30, 1908. The Commercial Trust Company of Philadelphia and the Guaranty Trust Company of New York are depositaries.

Electrical Engineer and Draftsman for Federal Service.

The United States Civil Service Commission announces an examination on November 23, 24 and 25 to secure eligibles from which to make certification to fill a vacancy in the position of electrical engineer and draftsman in the office of the supervising architect, Treasury Department, Washington, D. C., at $1,200 per annum, and vacancies requiring similar qualifications as they may occur. Applicants should apply at once to the United States Civil Service Commission, Washington, D. C., for application form 1312.

Civil Service Examination for New York State and County Service.

The New York State Civil Service Commission will hold an examination on November 21 to secure eligibles from which to make certification to fill a vacancy in the position of engineering draftsman, Public Service Commission, First District, at a salary ranging from $1,200 to $1,800 per annum. The last day for filing applications for this examination is November 14. Full information and application form can be secured from Charles S. Fowler, chief examiner, Albany, N. Y.

FINANCIAL REPORTS OF ELECTRICAL COMPANIES.

PORTLAND ELECTRIC COMPANY.

The Portland (Me.) Electric Company's income account for the year ended August 31, 1908, is as follows: Gross, $304,951; expenses, $124,871; net, $180,080; charges, $106,277; surplus, $73,803, which compares with a surplus of $44,191 for the preceding year.

CUMBERLAND TELEPHONE AND TELEGRAPH COMPANY.

The report of the Cumberland Telephone and Telegraph Company for the month of September and nine months ended September 30 is as follows: September gross, $508,130; expenses, $288,719; September net, $219,411; charges and taxes, $43,766; September surplus, $175,645, which compares with $157,042 for September, 1907. Nine months' gross, $4,554,713; expenses, $2,642,036; nine months' net, $1,912,667; charges and taxes, $341,847; nine months' surplus, $1,570,830, as against $1,295,813 for the previous fiscal year.

EDISON ELECTRIC ILLUMINATING COMPANY OF BOSTON.

The twenty-third annual report of the Edison Electric Illuminating Company of Boston, for the year ended June 30, 1908, shows as follows: Gross, $4,229,239; expenses, $2,261,344; net, $1,967,895; miscellaneous profits, $38,441; total net, $2,006,336; taxes, $397,584; balance, $1,608,751; interest, $54,988; dividends, $1,390,796; surplus, $162,967, as compared with $85,602 for the year 1907.

President Charles L. Edgar says: "The increase in connected load during the past year has been as great as during the preceding year, which was, up to that time, by far the largest in the history of the company. Taking into consideration the business depression, which has existed during the greater part of the year, this result is extremely satisfactory.

"As will be remembered, the price was reduced in June, 1906, from eighteen cents to fifteen cents, resulting in a very large increase in business. A further reduction from fifteen cents to twelve cents went into effect on July 1, 1908. It is confidently expected that this reduction will result in still larger business."

There are now connected to the system 938,670 incandescent lamps, 9,867 arc lamps and 39,122 horse-power in motors. The corresponding figures for 1907 are 863,313, 10,339 and 35,095.

At the annual meeting of the company directors were re-elected, with the exception that C. F. Adams, 2d, succeeded Robert Bacon, recently resigned.

MONTREAL STREET RAILWAY COMPANY.

The preliminary report of the Montreal Street Railway Company for the fiscal year ended September 30 last, shows gross earnings of $3,677,432, an increase of $173,789, and total income of $1,591,049, an increase of $136,958. There was a surplus, after charges and dividends, of $235,687, a decrease of $36,571. The sum of $200,000 was set aside for appropriations, leaving $35,687, a decrease of $40,454.

AMERICAN LIGHT AND TRACTION COMPANY.

The American Light and Traction Company reports net earnings for the twelve months ended September 30 of $2,579,266, an increase of $189,368, and surplus of $597,208, an increase of $114,620. Following are the figures, with comparisons:

Net earnings, $2,579,266, an increase of $189,368; dividends, $1,301,058, an increase of $75,048; balance, $1,278,208, an increase of $114,320; reconstruction reserve, $681,000, a decrease of $300; surplus, $597,208, an increase of $114,620; previous surplus, $2,720,820, an increase of $482,588; total surplus, $3,318,028, an increase of $597,208.

MASSACHUSETTS ELECTRIC.

The operating companies of the Massachusetts Electric have declared the same dividends as a year ago, which means a declaration of four per cent on Old Colony and five per cent on Boston & Northern Street Railway stocks. These dividend payments will put into the treasury of the parent company a total of $880,837, and after allowing for miscellaneous income and deducting $157,500 interest on the $3,500,000 notes, should enable the Massachusetts Electric to show a dividend balance of better than $750,000, or, say, 3.6 per cent.

AMERICAN TELEPHONE AND TELEGRAPH COMPANY.

The American Telephone and Telegraph Company has issued a financial statement for the nine months ended September 30, showing a surplus after dividends of $1,423,311, an increase of $1,169,220. The detailed income account for the period named is as follows:

Dividends, $10,034,016; interest and other revenue, $7,297,154; telephone traffic (net), $2,981,607; real estate, $120,134; other sources, $566,415; total earnings, $20,999,329; expenses, $1,571,755; net, $19,714,573; interest, $3,714,637; balance, $13,712,935; dividends, $9,289,024; surplus, $4,423,311, an increase of $1,169,220 over the previous year.

AURORA, ELGIN & CHICAGO.

The Aurora, Elgin & Chicago Railway's report for the year ended June 30, 1908, shows earnings as follows: Gross, $1,401,107, an increase of $69,122; expenses, $766,977, an increase of $44,697; net, $634,130; increase, $24,425; charges, $334,408; increase, $15,308; surplus, $299,722; increase, $9,117; preferred dividend, $155,000; balance, $144,727; common dividend, $93,000, leaving a net balance of $51,727.

MEXICAN TELEGRAPH.

The report of the Mexican Telephone and Telegraph Company for the month of August and six months ended August 31, shows as follows: August gross, $32,492; expenses, $17,881; August net, $14,611; six months gross, $196,925; expenses, $107,991, an increase of $7,787.

UNITED RAILWAYS OF ST. LOUIS.

The report of the United Railways of St. Louis for the month of September and nine months ended September 30, 1908, compares as follows: September gross, $887,344; decrease, $13,262; expenses, $554,164; decrease, $34,719; September net, $333,180; decrease, $8,543; charges, $234,380; increase, $1,976; September surplus, $98,800; decrease, $10,519. Nine months' gross, $7,860,624; decrease, $255,712; expenses, $5,073,080; decrease, $125,946; nine months' net, $2,787,544; decrease, $129,766; charges, $2,087,330; decrease, $96,399; nine months' surplus, $700,214; decrease, $33,367.

WESTERN UNION TELEGRAPH COMPANY.

The annual report of President Robert C. Clowry, of the Western Union Telegraph Company, for the year ended June 30, 1908, made to the stockholders at the annual meeting on October 14, shows that the capital outstanding is $99,817,100, of which $30,131.51 belongs to and is in the treasury. The revenues for the year were $28,582,212.09, a decrease of $4,274,194.16, and the expenses for the year were $25,179,215.33. The net revenue was $3,402,996.76, a decrease of $2,921,213.29. The profits were $1,670,746.70, a decrease of $3,233,402.29. The statement of expenses for the year showed operating and general expenses, including taxes, of $19,069,813.70; rental of leased lines, $1,546,-

181.87; maintenance and reconstruction of lines, $139,357.92; equipment of offices and wires, $423,861.84.

The net growth of the plant in poles and cables was 2,831 miles; in wire, 38,231 miles. There was a decrease in offices of 907, due principally to the fact that railroad companies have closed many small telegraph offices in consequence of the enactment of laws shortening the hours of labor. At most of these places messages are accepted and telephoned to an office of the company to be forwarded to their destination. Of the total of 1,359,430 miles of wire at the close of the year, 485,801 miles were of copper, and 873,629 of iron. The number of messages decreased 12,433,264, due to the depression in business and to the strike of operators, which began early in August of last year and continued until November 7. The average tolls per message transmitted by the company were the same as the previous year, but the cost so increased due to the strike that that branch of the business showed a small loss for the year. This loss ceased as soon as conditions became normal. Notwithstanding the abnormal expenses during the strike, the expenses for the year were reduced $1,352,980.87.

For the past few years liberal appropriations have been made for the maintenance of the company's line, and the plant is therefore in good condition.

The automatic printing telegraph owned by the company, and mentioned in the last report as having been put in operation at many of the principal cities, has been further extended to Washington, Cleveland, Cincinnati, Kansas City, Omaha, Denver and Nashville.

AMERICAN TELEPHONE AND TELEGRAPH COMPANY.

The report of all associated Bell Telephone operating companies, not including long-distance lines, of the American Telephone and Telegraph Company for August and eight months ended August 31, is as follows:

August telephone revenue, $9,950,400; operating and maintenance expenses, $7,292,500; net, $2,657,900; sundry earnings (net), $452,900; total net earnings, $3,110,800; interest, $614,500; available for dividends, $2,496,300, which compares with $2,270,300 for August, 1907. Eight months' telephone revenue, $78,792,100; operating and maintenance expenses, $57,892,300; net, $20,899,800; sundry earnings (net), $3,415,900; total net, $24,315,700; interest, $5,144,300; available for dividends, $19,171,400, comparing with $17,477,700 for the corresponding months of last year.

KINGS COUNTY ELECTRIC LIGHT AND POWER.

The Kings County Electric Light and Power Company, including the Edison Electric Illuminating Company of Brooklyn, reports combined earnings for the quarter and nine months ended September 30, compared as follows:

July 1 to September 30:	1908	1907
Gross	$898,659	$843,376
Operating expenses	431,219	446,895
Net	$467,440	$396,481
Replacement and depreciation	108.340	63,198
Balance	$359,100	$333,283
Charges	151,640	151,640
Surplus for dividends	$207,460	$181,643
Quarterly dividend	200,000	200,000
Surplus for quarter	$7,460	$18,357
January 1 to September 30:		
Gross	$2,675,382	$2 516,211
Operating expenses	1.855,879	1,292,972
Net	$1,419,503	$1,223,239
Replacement and depreciation	303,338	177,711
Balance	$1,116.165	$1,045,528
Charges	454,920	454,929
Surplus for dividends	$661,245	$590,608
Dividends paid	600,000	564,000
Surplus	$61,245	$26,608

The following statement was issued with the earnings:

"The earnings of the Kings County Electric Light and Power Company for the quarter ended September 30, as also for the nine months of the year to date, maintained an increase in gross business of six and one-half per cent in comparison with the previous year, when times were exceedingly prosperous; the company has effected radical economics, the operating expenses being three and one-half per cent less than the previous year, making a gain of eight per cent in net earnings over operating expenses.

"The depreciation charges have been increased by more than seventy per cent, but this does not represent money spent, but only earnings set aside as a reserve against which replacements are charged as they take the place of depreciated or abandoned property. The Kings County company makes a large depreciation charge each month as a regular expense, and the credit to this fund after deducting all actual expenditures is now in excess of $500,000. Notwithstanding this very large increase in depreciation charges, however, the earnings of the company after deducting fixed charges for bond interest show an increase of more than fourteen per cent over last year, and after deducting the dividend for the quarter still show a surplus of $7,460 as compared with a deficit of $18,357 for the same quarter of 1907.

"For the nine months of the year to date the report shows increased earnings of twelve per cent after deducting all charges, including bond interest, and a surplus over and beyond dividends of $61,245, as compared with $26,608 for the preceding year.

"The September quarter shows a gain in percentages over the average for the three quarters, which indicates clearly that business conditions are improving, and that the report for the full year will be even better than that for the nine months just ended."

The Increasing Application of Electricity to Agricultural Operations.

This subject is exhaustively treated in a series of articles appearing in the *Elektrotechnische Zeitschrift.* As in other countries, there is a growing scarcity of labor also in the farming districts of Germany on account of emigration to the cities. One result of this has been the development of machinery suitable to replace human labor and increase the productivity of agricultural operations. Thus the number of steam plows in use in Germany has increased from 836 in 1882 to about 3,000 in 1905; threshing machines from 75,000 to 300,000, while the number of farm laborers has diminished from 9,700,000 to 7,000,000 during the same period. The cost of maintaining the draft animals during the idle times, which is estimated to be about 290 million marks a year in Germany, has been another factor in causing an increasing use of machinery. America and England were first to introduce practical agricultural machinery, but Germany is at present not behind in this field. There are many electrically-driven machines now in use, as seed-grain cleaners, weeders, plows, mowers, automatic reapers and binders, potato harvesters, beet pullers, threshing machines, irrigating plants, etc. These are all machines intended to increase the raw product, but there is also a large field for machines that will diminish the cost of agricultural operations, as lifting, unloading and transporting arrangements in barns and fields, and considerable work has already been done in this direction. In the dairies electrically-driven machinery is also extensively employed. The articles contain many tables showing the comparative costs of identical operations by hand and by electrically-driven machinery, with the results invariably in favor of the latter, also numerous illustrations, among them one of an eighty-horsepower four-share plow in operation, the current being supplied from a nearby trolley line.

Electric Furnaces in Germany.

In transmitting the following report on electric furnaces in German steel works, Consul Thomas H. Norton, of Chemnitz, says that apparently it is only a question of time until the crucible processes will be entirely superseded:

"Hitherto electric furnaces in Germany have been used chiefly for the treatment of small quantities, but now the leading works are beginning to employ them on an extensive scale for handling large quantities of metal. At the close of 1907 one of the most important steel works in the empire engaged in the production of cast steel for gears, as well as of the softer varieties of malleable cast steel for automobile construction and for minor machine parts, decided to replace its battery of crucible furnaces by a large electric fusion furnace. The main cause for the change was the desire to materially lessen the cost of fusion while not lowering the quality of the steel, but, on the contrary, improving it, if possible.

"The old equipment consisted of thirty-two furnaces, each containing six crucibles with a capacity of seventy-seven pounds. They are replaced by a single electric furnace of 250 horse-power, capable of holding a charge of a metric ton (2,205 pounds). A duplicate furnace is likewise installed and kept as a reserve for emergencies.

"Electricity is supplied from the large works of a company near Cologne, which furnishes a three-phase current of 5,200 volts to quite a large territory near the Rhine for both power and illumination. Alterations in the current intensity are so slight that connection is made directly, without the interposition of a regulator, between the furnace and the transforming station. At the latter, a three-phase rotatory current, reduced to a tension of 110 volts, is supplied.

"The production of cast steel in this furnace has been carried on since the beginning of 1908 without interruption, and with such a degree of success that the results are well worthy the attention of American steel manufacturers. Details of the cost and process generally are herewith reproduced in some fulness, on account of the far-reaching importance of this revolution in the central feature of one of the leading industries of the United States.

"The main product of the furnace has been cast steel, containing about .06 per cent phosphorus, .03 per cent sulphur, and from .08 to .18 per cent carbon. Occasionally charges of tool steel have been cast, containing from .7 to 1.3 per cent of carbon, with and without the addition of nickel, chromium, or tungsten. The material employed is ordinarily slugs, cuttings, turnings, and other waste of wrought iron, costing from $14.28 to $15.47 per metric ton (2,205 pounds); $12.96 to $14.04 per short ton. A fusion, including the refining, lasts about five hours and involves a consumption of about 900 kilowatt-hours for one metric ton of cast steel. The entire charge of one ton is poured at once. When the furnace is kept in continual use the magnesite lining lasts for about seventy operations, *i. e.*, twenty to twenty-five days. A stoppage of five days is required for each renewal, but during this period the reserve furnace is employed.

"The cost of the electric current is exceedingly low, on account of the large amounts consumed. It amounts to four and one-half pfennigs (1:071 cents) per kilowatt-hour, so that the expense for a single operation is about forty marks, or $8.64 per short ton.

"The total cost of cast steel, thus produced, per metric ton, is as follows:

For	Cost.
Amortization of cost of plant	$1.19
Raw materials, including additions, chromium, etc	16.66
Electric current, including heating during intervals	10.71
Renewal of magnesite lining	2.85
Labor	2.38
Electrodes	.60
Water for cooling purposes	.12
Total	$34.51

"This amounts to $31.32 per short ton, and is materially less than the cost of crucible steel.

"The manufacturing firm notes in addition these advantages in the electric process, as compared with the old method: (1) Cheaper raw material can be employed in the place of the more expensive Swedish iron formerly required; (2) in fusing quantities of a ton at a time it is possible to produce homogeneous masses of a distinct, well-defined grade; (3) the molten steel leaves the furnace at a much higher temperature than when prepared in crucibles, is therefore in a more liquid condition, and is easily transferred to ordinary ladles, preparatory to pouring into the molds of small castings.

"These electric furnaces are arranged on the Stassano system, and are supplied in all sizes for charges varying from 400 pounds to ten tons, and are adapted for the fusion of metals of every kind. The construction is shown by the designs forwarded (and filed for inspection at the Bureau of Manufactures).

"The furnace for cast steel is constructed of iron plates, heavily lined with magnesite bricks. Carbon electrodes enter by three openings on the sides, and are so adjusted as to terminate slightly above the surface of the molten metal, whereby the heat of the arc is absorbed almost entirely by the contents of the furnace, and but a small portion is radiated upward, to be reflected from the concave dome.

"A thorough mixing of the component parts of a charge is effected by mounting the furnace on an axis, slightly inclined from the vertical. A steady revolution about this axis is maintained through a cogged connection, with a dynamo of five horse-power, the edge of the furnace resting on ball bearings. This rotation causes the lower layers to gradually rise to the top of the molten mass, and brings about a thoroughly uniform mixing. The electrode supports are inclosed in cylinders and surrounded by a current of cold water. These supports are in rigid connection with hydraulic cylinders, by means of which the movements of the electrodes are under perfect control.

"A fusion requires three and one-half hours to be complete; a further period of one and one-half hours is requisite for the removal in succession of phosphorus and sulphur, and the final deoxidation of the contents of the furnace. No interruption occurs in either the current of electricity, or in the supply of water for cooling the electrode supports, while the furnace is in rotation. Special devices have been provided for both purposes.

"The services of three workmen are required to conduct an electrical furnace, change electrodes, transport the raw materials, etc. Furnaces of the type in question are now being introduced in Germany for the treatment of other metals and alloys, and it is apparently only a question of time before the crucible processes hitherto in such general use will be completely superseded."

The Chicago Electric Club.

The Speakers' Committee of the Electric Club, of Chicago, Ill., announces the following programme for November: November 4, business meeting; November 11, address by William Carroll, city electrician, on "Street Lighting—Past Present and Future"; November 18, address by Thomas I. Stacey, treasurer of the Electric Appliance Company, on "Chicago, the Great Central Market"; November 25, Frederic P. Vose, attorney for the Electrical Trades Association, on "Contracts."

Expense of Conducting New York State Public Service Commissions.

According to a statement prepared by Secretary Travis H. Whitney and made public recently at the office of the Commission of the First District, the two Public Service Commissions are not costing the taxpayers of the State and city so very much more than did the commissions which they succeeded. The statement of the expenses of the commission is prefaced with the following:

"So much criticism has been made of the expense imposed upon the State and upon the city of New York by the two Public Service Commissions that it is important to make a comparative statement as to such expenses."

The statement contains the following comparative tables:

"The expenses of the Rapid Transit Commission (to which the Public Service Commission for the First District succeeded), estimated on its expenditures for its last six months (which ended in the middle of its fiscal year), were $921,459.10.

"The expenses of the Railroad Commission, estimated on its expenditures for its last nine months (which ended before the end of the fiscal year), were $101,578.20.

"The expenses of the Gas and Electric Commission, estimated on its expenditures for the last nine months (which ended before the end of its fiscal year), were $60,171.80.

"The expenses of the state inspector of gas meters, estimated on his expenditures for the last nine months (which ended before the end of his fiscal year), were $23,440.67.

"Thus the total annual expenses of the various commissions to which the present Public Service Commissions succeeded were $1,106,649.77."

Compared with these annual expenses are the following expenses of the two Public Service Commissions for the year ended June 30, 1907:

"The expenses of the Public Service Commission for the First District upon rapid transit matters under the Rapid Transit act requiring an engineering force of about 300 employés, $600,000.

"The expenses of the Public Service Commission for the First District to carry out its duties under the Public Service Commissions law and the Railroad law, $366,861.32.

"The total expenses of the Public Service Commission for the Second District under the Public Service Commissions law and the Railroad law, $234,282.09.

"Total expenses of the two Public Service Commissions under the Public Service Commissions law, the Railroad law and the Rapid Transit act, $1,201,143.41.

"It will thus be seen that the net increase in the expenses to the State and city for the two Public Service Commissions over the annual expenses of the officers whom they succeeded was only $94,493.64."

In conclusion Mr. Whitney writes:

"This increase is less than the average annual increase of the expenses of the commissions which were abolished, and shows that the two commissions have done not merely the work of the preceding commissions but also all of the work involved in the duties imposed by the Public Service Commissions law which had not heretofore been exercised by any state body.

"It is to be noted that the Public Service Commission for the First District did the rapid transit work under the provisions of the Rapid Transit act at an expense which is $321,459.10 less than the expense of the Rapid Transit Commission for its last year, although the number of employés on rapid transit work was greater than that under the Rapid Transit Commission.

"Omitting the expenses of the rapid transit work done by the Public Service Commission for the First District, it will be seen that the total expenses for the efficient regulation of public service corporations afforded by the Public Service Commissions law are $601,143.41."

The Rental Value of a Power Plant.

"The rental value of a power plant depends upon its character and efficiency to produce power cheaply.

"The cost of producing power in small amounts is very much greater than in large amounts, and the amount which the lessee should pay may be obtained in comparison with the cost of producing the amount of power required with a reasonably efficient plant with steam power or by some other means. Thus, supposing the power to be rented is water power and plant, its value can be determined by estimating the cost of producing a uniform power by water power, supplemented by steam power if necessary, and comparing the cost of producing the same amount of power by steam power alone, in each case adding such charges as the lessee is to assume. The difference, if in favor of the water power, will represent the value of the power for the length of time the estimated cost covered.

"If the power plant be a steam plant, it is possible that it has no rental value; that is, it may be so wasteful that it would pay to replace or change parts of it to bring it into an economical state. If it is an economical plant, and is to be run by the lessee, he should pay such rent as will cover depreciation and a fair rate of interest, and assume repairs, insurance and taxes, or pay enough rent to cover them.

"In the same way, if power is sold the lessee, the proper amount to pay per horse-power per year will vary with the amount which he requires.

"As the amounts of power grow smaller, the cost of producing it is larger, and therefore a larger price per horsepower per year must be paid.

"The charges for small amounts of power seem to vary from fifty dollars to one hundred dollars per horse-power per year; but each case should receive careful attention."—*From paper by Charles T. Main, mill engineer, Boston, Mass.*

New New York Transportation System.

Arrangements have been completed, it is announced, for the purchase from the Interborough Rapid Transit Company, of New York city, of the Pelham Park & City Island Railroad and the installation thereon of the American monorail system. At its meeting last week the Public Service Commission for the First District, New York, received the application for the change of motive power from horses to electricity and the installation of the monorail system, and referred it to a committee of the whole. It is anticipated that the system of transportation will be in operation three months after approval has been given by the utilities board.

A corporation known as the Monoroad Construction Company has been organized with a capital stock of $1,500,000, in which the Interborough company will have an interest, to construct and equip the road with the monorail system.

It will be remembered that this system is the one which was exhibited at the Jamestown Exposition last year.

At that time it was announced that a road between New York and Newark was to be built without delay. Legal obstacles were, however, encountered in places where the promoters of the project had every reason to believe there would be none, which have postponed that work.

Changes in the Electrical Inspection Service, New York City.

Commissioner John H. O'Brien, of the Department of Water Supply, Gas and Electricity, of New York city, has placed Charles F. Lacombe, chief engineer of light and power, in charge of the electrical bureaus of that department in all the boroughs, and at Mr. Lacombe's request has assigned Hubert S. Wynkoop, electrical engineer in charge of the Brooklyn bureau, as assistant engineer.

This action accomplishes a long-desired result, namely, the placing of the various bureaus of electrical inspection under one head in order to secure uniformity of routine and rulings throughout the entire city. Heretofore considerable confusion had been caused by the absence of a central authority to whom disputes, applications for approval of appliances and proposed changes in the rules might be referred.

The personal equation will be largely eliminated as to approval of appliances, materials, etc., by the formation of an advisory board, consisting at present of Mr. Lacombe, Mr. Wynkoop and Professor George F. Sever, of Columbia University, consulting electrical engineer to the department. The department has an agreement with the university to the end that the latter makes such tests of appliances as may be required. The well-equipped laboratories of the university will thus be available for the department, and all applications for approval which require tests will be referred to Professor Sever in the first instance, who will submit a report to the advisory board. The board will then submit a recommendation in the matter to the commissioner, whose approval makes the decision final. Frequent bulletins will be forwarded to the borough officers of the bureau, so that the engineers and chief inspectors of each borough will be advised simultaneously of the action taken.

With a realization that the department and the insurance inspectors are working along different lines of interest toward a common end, an arrangement is being made to effect closer relations with the underwriters and the lighting companies than have existed heretofore.

Considerable complaint has existed in the past over the difficulty experienced by contractors and material men—even by the department chief inspectors themselves—in securing general rulings on doubtful points or information in advance of changes in the rules or of approvals or disapprovals of appliances. It is hoped to overcome this criticism by using the electrical papers of the city to announce contemplated changes in the rules, so that interested parties may have an opportunity to present their arguments, and to give to the public from time to time substantially such information as will be issued to the borough officers of the bureau. Furthermore, except in the cases of grave danger, no changes will be put into effect "at once," and every effort will be made to avoid the unnecessary hardship to the electrical contractors that comes from too swift action.

The three officers of the bureau are all graduate engineers and experienced in the lines of work required of the Bureau of Electrical Inspection.

Improved Conditions in the Electrical Companies.

The gross business of three big electrical companies, says the *Wall Street Journal*, has shown an average improvement of close to forty-five per cent from the low point at which sales were running during the depth of the depression. The statement continues:

"At the present time the General Electric, Westinghouse Electric and Western Electric are doing a total gross business of about $94,000,000, as against $65,000,000 at the low point. This is an improvement in sales of $29,000,000, or forty-four per cent.

"The largest actual improvement has of course been shown by the General Electric, but in percentage of improvement the Westinghouse Electric outstrips either of the other two companies, a fact which very probably has considerable connection with the success of the reorganization plans.

"The present rate at which gross sales are running, the rate at the low point, the recovery and percentage of recovery for each of the three companies are shown in the following comparison:

Company.	Present Rate. Gross.	Rate Low.	Recovery	Per Cent. Recovery.
General Electric.	$42,000,000	$30,000,000	$12,000,000	40
Westinghouse.	22,000,000	18,000,000	9,000,000	69
Western Electric	30,000,000	22,000,000	8,000,000	36
Total.	$94,000,000	$65,000,000	$29,000,000	44

"In a general way the effect of the 1907 panic upon the sales of electrical apparatus has been to force the demand back to the standard obtained in 1903 and 1904. In the case of Western Electric the presence of special conditions in the telephone field reduced gross sales to a level with those for the year 1901."

A Communication from Mr. George H. Guy.

TO THE EDITOR OF THE ELECTRICAL REVIEW:

My attention has been called to the fact that my name has been unwarrantably used several times recently as "secretary of the New York Electrical Society," by way of giving apparently the endorsement of the society to the subject matter. The latest instance of this kind is the circulation of a postal by the Phillips Publishing Company, in which the attention of the members of the society is called to an article in a November magazine, in the words: "At the suggestion of Mr. Guy, secretary of the New York Electrical Society, I wish to call your attention to an inspiring article," etc.

I wish to say that this is not only impertinent, but absolutely unfounded. The society's year-book, with list of members, is freely given to those desiring information concerning the society. Application in this case was made for a copy, which was furnished, as usual, but without the slightest "suggestion" from me of any kind whatsoever. It is rather hard that such official courtesy should be abused.

I desire therefore to take this opportunity of saying that in no one instance where my name as secretary of the New York Electrical Society has been used in this manner has there been the slightest warrant for any consent or permission on my part, and I wish to say, if it need be said, that no one has a keener sense than myself of the impropriety that would be involved in such action by me.

Yours truly,

GEORGE H. GUY.

New York, October 26.

Approves Zone Basis of Fare Collection.

The up-State Public Service Commission, New York state, on October 14 in dismissing a complaint seeking reduction in fare from ten to five cents between Albany and Watervliet sets forth that there is no injustice in the practice of street railway lines in fixing their rates of fare on a zone basis instead of a mileage basis.

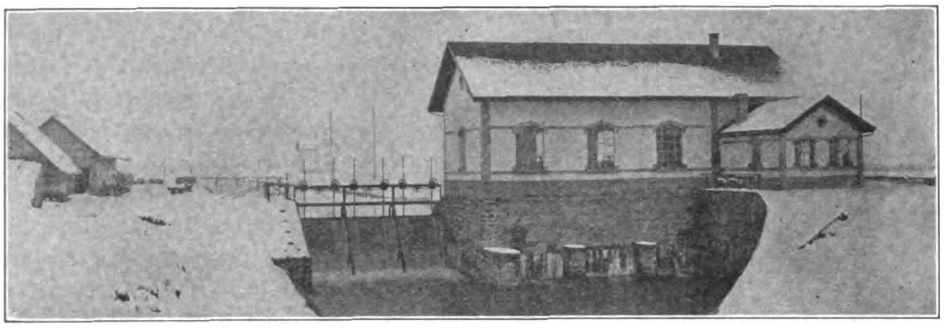
Illinois Central to Electrify Chicago Tracks.

Electrification of all tracks of the Illinois Central Railroad within the city of Chicago, Ill., was authorized at the annual meeting of stockholders on October 21. The stockholders also passed a resolution urging the directors to "proceed with all reasonable despatch in electrifying the service."

A Practical Application of Asynchronous Generators.

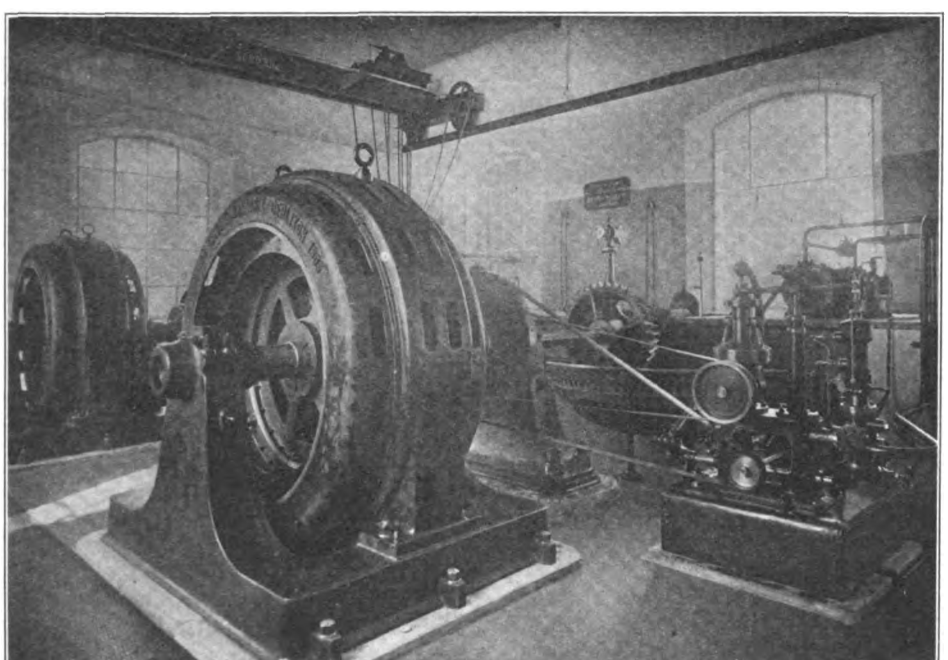
By Frank Koester.

AN interesting example of the parallel operation of two asynchronous generating stations with a single synchronous station is found at the Rhein Binnen canal, Switzerland, and the following brief description includes the essential features of this installation.



Main Generating Station, Montlingen.

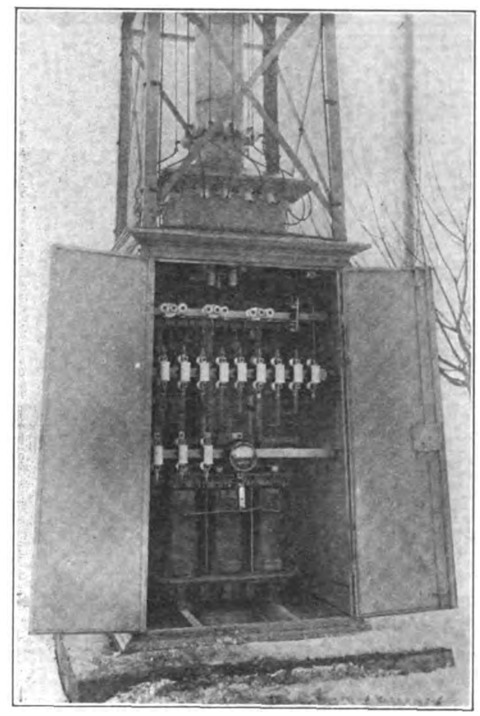
In order to prevent the Rhein from overflowing its banks during flood season in the region near Lake Constance, the governments of Switzerland and Austria have taken steps to regulate the flow by means of canals. They built on the Austrian side, besides several small canals, the Vorarlberger Binnen canal, and on



Interior of Synchronous Generating Station.

the Swiss side, the Rheintalischer Binnen canal. The latter canal, owing to the contour of the region, is constructed with three levels: One has a drop due to irregularity of water supply of from 9.8 to 11.5 feet; another from 17.5 to 21.2 feet, and the other from 31.8 to 35 feet. These heads are respectively utilized by three power plants. One is located at Lienz, another at Blatten three miles below, and the third at Montlingen, 2.4 miles below Blatten. For an economical reason the Oerlikon Company, of Oerlikon, Switzerland, which supplied the electrical equipment for all three stations, and the transmission system, proposed to make the station at Montlingen the main plant and those at Lienz and Blatten auxiliary plants, and equipped the former with synchronous, and the latter with asynchronous, generators, operating them in parallel.

The auxiliary stations with their asynchronous generator equipment do not require special excitation, as they are thrown on the line after the main station is in operation. Owing to the characteristics of an asynchronous generator, it is only necessary that they be near synchronism before being thrown on the line, thus doing away with synchronizing apparatus, delay in synchronizing, and skilled attendants. The whole regulation is done from the main plant. The disadvantage is that the auxiliary plants depend on the main plant for excitation, which also has to furnish the charging current for the line, thus forcing the synchronous generators to work under a low power factor, which is increased as more asynchronous generators are thrown on the line.



Type of Street Transformer Station.

This disadvantage, however, is greatly reduced by the lowering of first cost and maintenance of the auxiliary plants.

The main plant at Montlingen is at present equipped with three 250-horsepower Francis turbines, mounted upon vertical shafts and bevel geared to synchronous, three-phase generators of 10,000 volts and fifty cycles, making 250 revolutions per minute. Each generator has its own exciter mounted on the overhanging shaft. The generator leads are bare, mounted on insulators and run in trenches to the switchboard.

The switchboard is divided into five panels, three for generators and two for outgoing lines. Each generator panel has a main and exciter ammeter, the lever for the generator oil switch, and a hand wheel to control the excitation. The hand wheels can be interconnected by a shaft so that they can be operated simultaneously. The phasing of the synchronous generators is done with only one-phase lamp and a voltmeter, which are mounted on one of the feeder panels. Each of the lines is equipped with an automatic oil switch and an ammeter. One integrating wattmeter totals the entire output of the plant. The switchboard contains only low-tension apparatus; all the high-tension switch gear is located in reinforced concrete compartments in the switching room behind the switchboard.

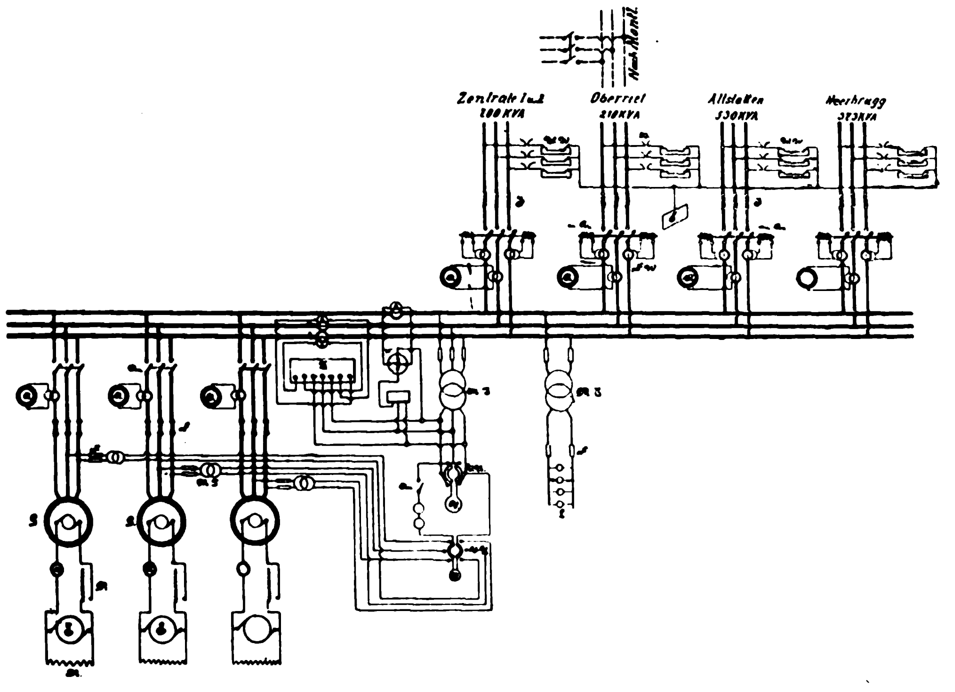


DIAGRAM OF CONNECTION, MONTLINGEN STATION.

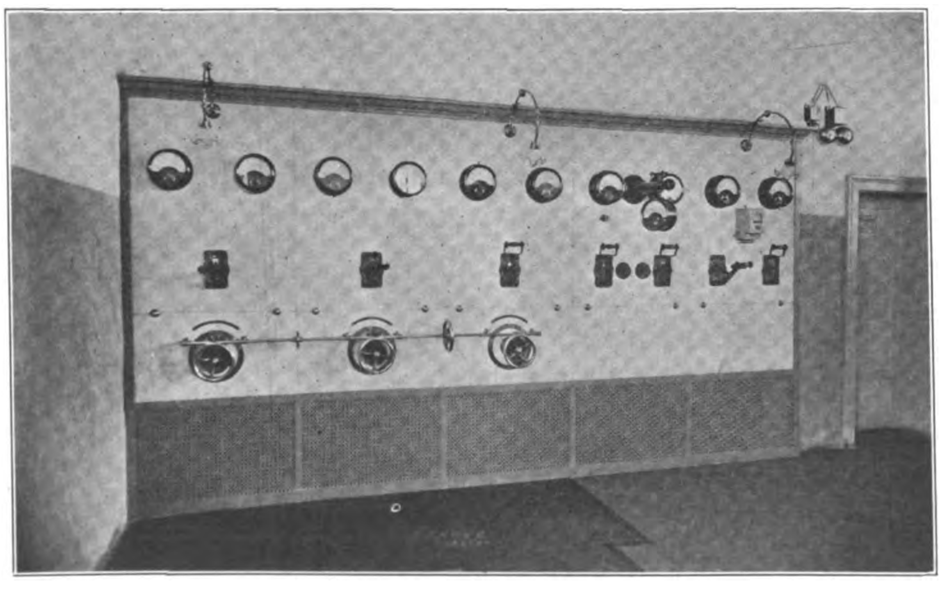
A=Ammeter.
V=Voltmeter.
W=Wattmeter.
Z=Integrating Wattmeter.
Au=Switch.
Auau=Automatic Switch.
VU=Bus-Bar Voltmeter.
S=Fuse.
R=Rheostat.
SW=Potential Transformer.
MT=Series Transformer.
I=Choke Coil.
WW=Water Rheostats.



SWITCHBOARD OF SYNCHRONOUS GENERATING STATION.

In the room above this are the protecting devices, each phase having a choke-coil and series of horn lightning arresters, connected to water rheostats. To properly inspect the latter two, they are provided with disconnecting switches.

The outgoing feeders leave the switching house on the third floor. For lighting the station there is installed a 1.5-kilowatt single-phase transformer, and for operating the motors in the repair shop there is a six-kilowatt, three-phase transformer.

The two auxiliary stations are in every respect, in regard to equipment, identical. Each plant has a 250-horse-power Francis turbine, similar to those in the main station, also operating the generators by bevel gearing. The asynchronous generators are 10,000 volts, fifty-cycle, operating at 250 revolutions per minute. The equipment of the switchboard and switching room is similar to that of the main plant, with the elimination of the apparatus for excitation and synchronizing apparatus.

The receiving current from the two asynchronous stations and the distribution of power is controlled from the synchronous or main plant at Montlingen. From here run lines to Oberreit, Alstätten and Heerbrugg, the latter two being connected by a separate line, thus forming a ring system. At Alstätten there are three 100-kilowatt transformers, stepping down from 10,000 to 2,000 volts. In Heerbrugg there are two 100-kilowatt transformers stepping down from 10,000 to 230 volts. The 2,000-volt current is distributed to a number of smaller transformer stations which are either of masonry or steel, a type of the latter being shown in the accompanying illustration. The current is used chiefly for induction motors for manufacturing purposes, and as there is no separate lighting curcit, the current is distributed by the three-wire system.

Long Acre Electric Light and Power Company.

The Long Acre Electric Light and Power Company on October 24 got from Justice Bischoff, in Special Term of the Supreme Court, a writ of certiorari to review the action of the Public Service Commission for the First District, state of New York, denying its application for permission to issue $10,000,000 preferred stock with a specified dividend of seven per cent; to issue $50,000,000 worth of six per cent, fifty-year gold bonds, only $12,000,000 of which is to be issued at present, and for permission to install electric wires and an underground system.

The company also demanded a rehearing of the entire matter, and the court directed the Public Service Commission to file in the Supreme Court the record of the hearings before it.

The petition on which the writ was issued was signed by John C. Sheehan as vice-president of the Long Acre Electric Light and Power Company. He set forth that the original application of the company to the Public Service Commission was refused, and that on October 23, after a rehearing, the Public Service Commission again denied the application.

The American Street and Interurban Railway Engineering Association.

Report of the Wednesday Afternoon and Friday Morning Sessions of the Convention Held at Atlantic City, N. J., October 12 to 16.

WEDNESDAY AFTERNOON SESSION.

THE Wednesday afternoon session of the American Street and Interurban Railway Engineering Association was called to order at 2.30 o'clock, the first order of business for the afternoon being the report of the Committee on Control. The report of the previous sessions of this convention, which was held at Atlantic City, N. J., October 12 to 16, was given in last week's issue of the ELECTRICAL REVIEW.

E. W. Olds, chairman of the Committee on Control, explained that it had not been possible for the members of the committee to devote to the work of preparing the report the proper attention needed to give it the necessary completeness.

The report contained two contributed papers, one by F. E. Case, of Schenectady, N. Y., describing the Sprague-General Electric automatic control, and the other by William Cooper, of Pittsburg, Pa., describing the controlling apparatus manufactured by the Westinghouse Electric and Manufacturing Company.

The discussion of this report was opened by Paul Winsor, of the Boston Elevated Railway Company. He called attention to the commutation of the brushes which are now being placed on the market, and stated that the brushes and commutator will stand tremendous overfeeding. During the last year or so, in Boston, the company has changed the resistance steps on every equipment on the road in order to get an even control. Mr. Cooper in his paper considers an acceleration of five miles per hour possible. Mr. Winsor did not think this could possibly be the case. He said that in elevated service an acceleration of this nature would throw passengers from their seats. His company believes very strongly in automatic features of control. There has been trouble caused by the dash-pots sticking. In service he gets about a mile and a half acceleration on the level. With a heavily loaded car it is not as high as that. There is considerably less trouble with automatic equipments now than there was a few years ago. In his opinion, however, the platform controller, where it can be used, is preferable. Mr. Winsor described the relay system for indicating, which utilizes a buzzer or alarm bell to indicate to the motorman that he is starting up too fast.

In discussing this report, Mr. Doyle stated that in New York his company had made a number of observations on the operations of motormen, and had discovered that there was a difference of from thirty to thirty-five per cent in the amount of current used under similar conditions. He was of the opinion that if the manufacturers of controllers could devise something that would indicate the extent of coasting of trains and the correct acceleration, that a reduction in current consumption could be secured. His scheme for measuring current used was to employ an ordinary time clock, which, as soon as the motorman shut off his controller, would start. While the train was coasting the clock would run and measure up the amount of time spent by the train in coasting. Mr. Doyle believed it would be a good plan to have the Committee on Control or the Committee on Maintenance give this matter consideration, and after some discussion a motion to this effect was adopted.

Mr. Munger stated that after a car had been overhauled and was about ready to be placed in service, the shopmen take the car out on the track and an ammeter is placed in the motor circuit. This is a direct-current ammeter, reading up to 500 amperes. One man handles the car while the other watches the ammeter to see that every point is taken easily. If the car does not notch up satisfactorily it is taken back into the shop and the trouble is located and adjustments made in the resistance until the car accelerates perfectly. The man who reads the ammeter has a stop-watch, and he notes the length of time consumed in the acceleration, which is taken from starting up to the point where the motors go into full multiple with all resistance out. Mr. Munger thought sufficient attention was not given to the matter of coasting, and he said that it was necessary every once in a while to bring up a number of motormen who paid no attention whatever to coasting. If a device could be procured which would keep a record of the amount of coasting done, it would be a valuable adjunct to the service. The matter of multiple-unit control for city service, he said, should receive attention, but if automatic acceleration could be secured, it was better than anything a motorman could do, no matter how careful he was in notching up. While the automatic feature may be charged with failures once in a while, it compares more than favorably with the failures which are the result of the motorman's notching up his car too fast.

Mr. Case, of the General Electric Company, said that a careful analysis had been made of the sticking of the dash-pots, and it had been found that it was due in a great measure to the condensing of moisture in the dash-pots when the car was laid up. This moisture runs down between the plunger and the cylinder and causes sticking. As the clearance between the plunger and the cylinder is very small, it requires only a very little moisture to cause trouble. He believes that with new designs this difficulty has been entirely overcome, because, when the relay is at rest there is no space within the dash-pot, and consequently no moisture can be precipitated to cause sticking.

Mr. Cooper, taking up the statement made by Mr. Winsor with regard to acceleration and retardation, stated that five miles acceleration or retardation could be secured with perfect control. Recent breaking tests have been made, which demonstrate that a retardation of five miles an hour can be secured without any uncomfortable jolting.

In answer to a question concerning the use of the ammeter and stop-watch, Mr. Munger stated that the rate of acceleration is adjusted by the stop-watch, and the effort is made to adjust the resistance so that every tooth and peak is the same. The time for full acceleration is fixed at eleven seconds. Mr. Munger also stated that adjustments were made every 60,000 miles.

The report of the Committee on Power Distribution was presented by W. J. Harvie, chairman. This report included a paper entitled "Application of the Theory of the Catenary to Electric Railway Work," by R. L. Allen, Syracuse, N. Y.

The report is divided into a discussion of the following subjects: Feeders, working conductors, return system, conduit system. It seems to be the standard practice with low-tension underground feeders to use saturated paper-insulated, lead-encased cables, the paper being five-thirty-seconds inch in thickness, and the lead from one-eighth inch to five-thirty-seconds inch in thickness. One large company is using five-thirty-seconds inch rubber insulation with a triple-braid cover without lead sheath. This company seems to endorse this method without hesitation. It seems to be the general opinion that some kind of fireproof protection is needed on the outside of the lead cable sheath in manholes. Some roads are using asbestos saturated with a solution of silicate of soda. A split-tile protection is recommended by one of the large roads. The majority of reports received by the committee indicate the use of No. 00 round wire on city and interurban work for ordinary trolley conductors. A number of companies, however, are using No. 0000 wire on interurban work and for renewals on city work. Regarding a standard height for trolley wire, the committee believes it good practice and recommends that height of trolley wire above top of rail be standardized at nineteen feet. The majority of roads reporting show the use of clinch ears on work now in service. Some roads, however, on which grooved trolley wire is used, are employing mechanical clips, but they find that when these mechanical clips are to be replaced it is usually necessary to substitute the clinch ear. It appears that electric railway companies are using all types of straight-line hangers and insulators, with the round-top bell-type predominating. It is the experience of electric railway companies that both wood and iron poles are subject to excessive deterioration at the ground line. Many companies have begun the practice of using so-called wood preservatives for wood poles, but up to the present time none of these has been able to show definite results. For iron poles the committee recommends without qualification the use of an iron sleeve shrunk on all iron poles at the ground line. This sleeve should be two feet in length, and so placed on the butt section as to have the middle point of the protecting sleeve at the ground line when the pole is set in place. The committee recommends that iron poles be purchased complete with this protecting sleeve. Of six roads reporting, three use the over-running type, and three the under-running type of third rail. Wood, reconstructed granite and composition insulators are used on the over-running type of rail. Wood, porcelain, semi-porcelain and composition insulators are used on the under-running type. The spacing of third-rail supports is generally ten feet, with a maximum in some instances of eleven feet, and a minimum of five feet. The weight of brackets varies between nine pounds with the over-running rail, and thirteen to twenty pounds for the under-running rail. The committee recommends a spacing of ten feet on all third-rail construction where thirty-foot conductor rail is used, and eleven feet where thirty-three-foot conductor rail is used. None of the companies reporting over-running third-rail construction uses protection throughout, while the under-running type is protected by wood or fibre. The majority of companies reporting show the use of No. 0000 grooved trolley wire for catenary work. The committee recommends this size and shape. All companies show the use of the mechanical clip, and there seems to be no doubt that this will continue to be modern practice. A rigid form of suspender is recommended by the committee. For messenger cable the committee recommends the use of the highest strength cable that can be obtained, in order to develop the full advantage of the catenary type of construction. The cable should be of unwiped wire. The subject of insulating supports for the messenger cable on high-tension service resolves itself into the use of porcelain entirely, the shape of insulators depending largely upon the voltage used. Strain insulators for heavy strains should also be made of porcelain. For steady strains and pull-offs the use of wood is permissible where moderate voltages are used, and a combination of wood and porcelain for higher voltages. A more recent development in supporting devices for catenary work indicates the use of structural steel bridges rather than poles.

In the paper contributed to the report by Mr. Allen, the following conclusions are presented: The use of a light plow steel messenger cable strung to a small sag. The hangers themselves should be as light and flexible as is consistent with strength and durability. The hangers should be spaced twenty or thirty feet to take care of the expansion or contraction. There is no reason why spans of 300 feet or more can not be used.

The discussion of this report was opened by a communication from R. D. Coombs, of the Pennsylvania Railroad. Mr. Coombs endorses generally the suggestions made by Mr. Allen, and states that no system can be successful which does not practically eliminate sparking and undue wear of the current collector. At present no definite decision can be made as to whether the single catenary construction or the secondary catenary construction is better suited for eastern climatic conditions and American operating requirements. The successful type must accommodate itself to changes in temperature and provide a trolley wire on which the collector may run smoothly. From an operating standpoint the construction should not involve unnecessary supports over the tracks, and long spans are therefore desirable. Mr. Coombs is of the opinion that spans in excess of 300 feet will be both economical and practicable.

Contributing to the discussion of this paper, Mr. Ayres stated that he had originally equipped his road with trolley wire and mechanical clips. A strong tension had to be applied at the base in order to keep the collector on the wire at high speeds. A heavy hammer blow was developed at the hanger, which caused cutting and kinking. It was found expedient to throw out the mechanical clip and use an appliance with copper ears. This gives better results and puts the wear on the lips of the ear, which can be replaced, rather than on the trolley wire, which is more expensive to replace.

Mr. Reed stated that in his opinion, if there was a breakdown in the insulation of a lead-protected cable, the trouble was accentuated by the metal covering.

Mr. Winsor stated that one of the reasons why his company had tried cables without the lead cover was due to the fact that if a bad short-circuit occurred on an underground cable, the trouble did not stop there. Other cables are affected, sometimes at the same time, or, more often, the trouble turns up a good deal later.

Mr. Corning stated that he had had much trouble due to the burning out of lead cables, and in order to guard against this the practice had been introduced of cutting the lead sheath in each manhole, taking a ring out of the sheath about a quarter of an inch wide, and filling the space with rubber tape, heating it, and making what might be called a rubber joint at each of these points. The sheath is made continuous again by a short copper wire around the joint to take care of the return current on the sheath.

Mr. Palmer stated that varnished-cambric cable was being used a good deal more extensively than many members of the association were aware. He knew of large orders which had been placed lately for a good deal of construction, and it was because of the trouble caused by electrolysis that a decision was made in favor of the cambric-covered cable.

Mr. Kelsay stated that his operating conditions were rather extreme from the standpoint of height of trolley wire. He has a limited service where a car operates on a wire from fourteen to twenty-two feet high. The state law requires the trolley wire to be twenty-two feet over railroads. There is another piece of road which is forty miles in length, where the trolley wire is very low, in some cases fourteen or fifteen feet. He has tried to maintain poles so that they will operate successfully over the range from fourteen to twenty-two feet. This is a condition which should not be imposed on any trolley.

Mr. Hayward stated that his road had been compelled to enter into agreements with railroads to maintain the trolley at twenty-two feet at the crossings. It seemed to him that this requirement introduced an element of danger. A pole that is built to ride on a trolley wire of the standard height of nineteen feet is more liable to come off the wire at twenty-two feet than at nineteen feet.

The session was then adjourned to meet Friday morning.

FRIDAY MORNING SESSION.

The first matter for consideration was the report of the Committee on Car and Car-House Wiring.

The committee reported that it had been unable to give proper consideration to the question of whether it was possible to construct standard specifications for car and car-house wiring. The rules of the National Electrical Code concerning the installation of heaters, the size of bonds, and the lighting of cars, were made a part of the report, and the rules which were adopted by the Electrical Committee of the Underwriters' National Electrical Association as a result of a conference with representatives of the committee and representatives of various heater manufacturing companies were given as follows:

"Truss plank heaters to be mounted on not less than one-quarter-inch fire-resisting material, the legs or supports for the heater providing an air space of not less than one-half inch between the back of the heater and the insulating material."

Concerning outlets, the following paragraph is provided:

"Each outlet to be provided with an approved porcelain receptacle or an approved cluster, no lamp consuming more than 128 watts to be used."

The code was also altered to include the following rule:

"All lighting and stationary motor circuits must be thoroughly and permanently connected to the rails or to the wire leading to the outside ground return circuit."

Mr. Ayres said that it was his opinion that in many cases the Underwriters established rules which were too stringent and burdensome. The requirement that truss plank heaters should be mounted so that the current-carrying parts are four inches away from woodwork is certainly unnecessary and absurd. As far as the size of lamp was concerned, he did not see why street railway operators should be limited in the size or the current consumption of incandescent lamps.

Rule 34 of the National Electrical Code, which reads: "Lighting and Power from Railway Wires. Must not be permitted, under any pretense, in the same circuit with trolley wires with a ground return, except in electric railway cars, electric car-houses and their power-stations; nor shall the same dynamo be used for both purposes."

He said that his company had an office building and a number of waiting rooms lighted from its own circuits. This is perfectly proper, and it should not require any special dispensation to do it. The rule ought to be modified so that electric railways could use their circuits for lighting under proper construction anywhere.

Mr. Roberts said he thought the committee should take up the matter of procedure in the case of lightning storms, and also the wiring arrangements of cars laid up in the car-houses at night. He said there should be some standard established, because it has been his experience that different inspectors look upon the installation in an entirely different way.

The report of the Committee on Operating and Storage Car-House Designs was presented.

The report stated that the idea of setting forth the principles of a standard car-house design was dropped because it was shown that, however desirable it might be from some points of view, the standardizing of car-house designs is impracticable for the reason that the outline of a car-house is governed by the size, grade and outline of the lot, the requirements of the road in question, its geographical position, and the ordinances of the city or town in which it is located. The subject is treated in the report by considering the principal problems entering into the designing and operating of storage car-houses.

The discussion of this report was opened by M. Schreiber, who said that the track layout should be made as flexible as possible, and that in yards, if practicable, it is desirable to keep the cars moving head on, irrespective of whether it is necessary to approach the barn in either direction. If the terminal is on a main line, the arrangement of special work should be such that the least interference is presented to regular operation.

To meet present conditions in car-storage houses a three or four-track bay seems to be best suited. This allows a low pitch and short-span roof. The report of the committee states that the three-track bay is objectionable, but Mr. Schreiber considers that this arrangement is sometimes very desirable, especially where the barn is a long one or when in dividing up the property the width does not work out in multiples. He did not agree with the committee in the matter of heating, which considered that the use of hot water was especially meritorious with forced circulation. The report also stated that the heating apparatus should be placed in a room cut off from the remainder of the house by fire-proof walls, and should be located centrally with regard to the places to be heated. Mr. Schreiber considered that if the area was large enough to justify a blower system or hot air, that this was the only heating system to install.

Mr. Adams said that he was not quite sure that the committee's recommendation to use flush transfer tables was a good one.

Mr. Winsor said that his company has twenty-four or twenty-five operating houses, and uses nothing but flush transfer tables. The flush table will allow the use of the whole space of the table at night for car storage. There are only a few hours of the day when all the storage room is needed for cars, and this is at a time when cars are not being shifted.

Mr. Lindall did not agree with Mr. Winsor that the flush transfer table was a good thing. It limited the movement of cars in the house at night after the cars are all put in, and handicapped the car-cleaning end of the work.

Mr. Adams called attention to the suggestion in the report which read as follows: "While the Underwriters stipulate that no section of the house shall contain more cars than amount in value to $200,000, the committee believes that no road should expose more than a certain per cent of its rolling stock to the risk of destruction by any one fire, as the loss of cars means the loss of revenue."

He said that the Fire Underwriters desired to limit the figure to a somewhat lower valuation, but that the committee had finally persuaded them to hold up to the $200,000 valuation.

E. W. Olds stated that a considerable advantage would be gained if the companies built their car-storage houses so that one section could be burned out entirely without affecting other portions of the storage area. He also raised the question as to whether the flush transfer table should be recommended for general shop service.

Mr. Lindall replied that the flush transfer table has a decided advantage, inasmuch as material can be handled by trucks across the floor much better than with a pit transfer table. He did not know that there were any other advantages.

The report of the Committee on Way Matters was presented by Mr. Schreiber.

This report included contributions by C. B. Voynow, on "A Proposed New System of Street Railway Construction"; by H. M. Steward, on "The Life of Manganese Steel Rail on Curves," and by Howard F. Weiss, on "The Open-Tank Method of Preserving Timber."

Mr. Voynow's suggestion consists essentially of a track built with a T-rail with a projecting flange above the tread, which would guide the car, and a flangeless wheel. The flange on the rail would take the place of the flange on the wheel with some of the following advantages: The entire system would be of unbroken main line. The manufacture would be simplified, and most of the system could be built of the same rail as straight track. It would cost at least twenty-five per cent less than at present. There would be no possibility of car derailments on account of the tongue kicking or riding on a movable tongue. The rail section would be easy to roll, would conduce to a long life of the head, and the joints would have longer life on account of its being centre-bearing for both car and wagon traffic. The wheel would wear better because it could be chilled through the entire surface, and the chill made deeper. It would be simple to manufacture so far as the casting is concerned, as well as grinding or finishing.

In opening the discussion on Mr. Voynow's contribution, G. L. Wilson said that he thought this form of design would invite all passing teams to use the rail. He did not believe it would be advisable to favor such a radical change in the rail section. He thought that the resistance offered by dirt and obstacles on the track would be much increased, and the liability of derailment greater than at present.

C. Boardman Reed said he thought that on special work, particularly at curves, where guard rails are now required, a rail of the type suggested by Mr. Voynow would have to be renewed much oftener.

W. J. French stated that during the past year, in Utica, N. Y., and also in Syracuse, permission had been secured to use T-rail in the paved streets. These streets are used for ordinary city traffic, and it has been demonstrated that the pavement wears well and that there is no more danger from breakage of wheels than with flat girder rail. Also, the construction is more stable and rational than the girder construction.

R. C. Cram, of New Haven, stated that it has been found that if the authorities can be convinced that T-rail construction is the best for all concerned, the question simply resolves itself into the proper pavement.

Mr. Voynow said that the advantages of this type of rail were hardly appreciated. He would not consider it an ideal rail, but its advantages as far as special work, wheel construction, less exposure of rail in the street, effect on pavement and noiselessness are concerned, are very great. As to interurban cars entering the cities, all the tracks that are laid at present in cities have the maximum depth of their trams about one and one-quarter to one and one-eighth inches, and interurban cars having a standard wheel flange of one and one-eighth inches can not enter the city tracks. This rail makes provision for such service.

The contribution by Mr. Weiss to this report was presented, and the author explained that the only companies that have really taken the question of wood preserving up on a practical basis are some electrical companies in California. The working outfit costs about $400, including a tank with a second-hand boiler and pump. The various preservatives are injected into the body of the pole. The Government simply carries out the work to the point of proving its value to the companies.

This contribution to the report created considerable discussion. Ernest F. Hartmann stated that the application of a preservative is better than applying an oil paint. Oil is a preservative, but it is also a vegetable compound and decays the same as any other vegetable matter. The antiseptic action of any preservative material on partially decayed wood will help to a considerable extent. The Boston Elevated Railway Company is treating its ties by the open-tank immersion process, and it costs the company from sixteen to eighteen cents per tie. Something like 90,000 ties have been treated, and it is understood that the results are entirely satisfactory. Crossarms have been treated at Bangor at a cost of $8.68 per thousand feet. At Norfolk gum trees have been treated by the open-tank method, at a cost of twenty-three cents per tie. At Columbus, Ga., the cost of treatment is thirty-one cents per tie. At Denver the cost of treatment is seventeen cents per tie.

Mr. Cram said that his experience had taught him that it is not a good thing to treat green timber with any kind of preservative process.

Mr. Hartmann replied that the trouble with this installation was that no provision was allowed for drainage, and that when the blocks became thoroughly wet they split up. If the wood-block pavement were properly grouted there would be no trouble.

FRIDAY AFTERNOON SESSION.

It was decided to pass over the discussion of the question box, and the first business of the afternoon session was the hearing of the report of the Committee on Economical Maintenance.

The report recommends that, under average conditions, the practice of shopping car bodies for general overhauling yearly is the most economical. The committee recommends that the replacement of steel tires or steel-tired wheels with rolled-steel wheels be given careful consideration. The report also suggests that where track and special work is particularly severe on flanges, and where conditions permit a material reduction in the diameter of the wheels by wear, the rolled-steel wheel may be found to be more economical than the cast chilled wheel. The committee feels that there is general need of better knowledge on the part of persons responsible for the use of material as to the most suitable material for the purpose required and the checking of such material to determine its quality. It is suggested that the association could do valuable work in the preparation of suitable specifications for materials, and recommends for consideration the appointment of committees for this work. The committee is so convinced of the necessity of a system of accounting which would show the minimum average and maximum costs of maintenance for various classes of equipment that it recommends the appointment of a committee jointly with a committee from the Accountants' association for the purpose of giving this subject thorough consideration.

This report was discussed at length, it being the consensus of opinion that standard specifications for the purchase of material would help the purchasing agents very materially in securing the best material at uniform prices. The suggestions for the establishment of standard forms of accounting would also allow a comparison of maintenance charges, which would effect great economies in every system.

Following the discussion of this report, several amendments to the constitution and by-laws were made.

The report of the nominating committee was presented as follows: President, Paul Winsor, Boston; first vice-president, F. H. Lincoln, Philadelphia; second vice-president, W. H. Evans, Buffalo; third vice-president, W. J. Harvie, Utica, N. Y.; secretary and treasurer, John W. Corning, Boston. Executive committee: William Roberts, E. O. Ackerman, L. L. Smith, Martin Schreiber.

It was voted that the secretary be authorized to cast one ballot for these candidates.

On motion of Mr. Roberts a cordial vote of thanks was extended to Mr. Simmons, the retiring president, for the able and courteous manner in which he had conducted the affairs of the association.

President-elect Winsor was escorted to the chair and addressed the members briefly, after which the convention was adjourned.

The American Street and Interurban Railway Transportation and Traffic Association.

Report of the Wednesday and Thursday Sessions of the Convention Held at Atlantic City, N. J., October 12 to 16.

THE report of the Monday and Tuesday sessions of the American Street and Interurban Railway Transportation and Traffic Association was printed in the last issue of the ELECTRICAL REVIEW.

The Wednesday session was called to order at 10 A. M. with President Allen in the chair.

The discussion of the report of the Committee on Electric Mail Service was opened by Gen. O. H. Harries. This report, which was compiled by C. H. Hile, was composed largely of extracts from the United States Post-Office Department reports on electric railway mail service. This indicated the general opinion of the Government with regard to the compensation which should be allowed electric railway companies for the carrying of United States mail.

General Harries pointed out that the electric railways did not carry, as a rule, any other variety of business at a loss. There was no reason why the electric carrier should discriminate in favor of the Government, but he stated that very little could be accomplished as long as the electric railways continued to carry the mails at the present rate. So long as one company accepts mail at a low rate, this rate will be made the average compensation to all the others. There will be no action by Congress either so long as companies are found who will carry mail at the existing rate. The blame for this condition rests on the carrier, who insists on doing business without profit. The only remedy for this condition is for all the companies to refuse to accept contracts on the present basis.

Mr. Hippee stated that his company, in Des Moines, Iowa, carried United States mail in pouches and also carried four mail boxes on each car. The mail is collected at the main station by Government collectors and mail carriers, and the pouch mail is carried to substations and to the eastern side of the city. The mail is put on the cars by a representative of the Post-Office Department, and taken off the cars by one. The company receives compensation at the rate of three cents per mile for closed-pouch service. There is no limit to the number of pouches that can be carried, except that there is a general understanding with the postmaster that a car shall not carry more than three or four pouches on the front platform.

Mr. Brady, of Anderson, Ind., stated that the Indiana Union Traction Company has had a limited experience in handling material on interurban lines. It has two contracts, both of long standing, one of which involves the handling of mail by pouches from Anderson to Alexandria, a distance of about ten miles, and for which compensation is received at the rate of three cents per mile. The total compensation is between $45 and $50 per month, which is lessened somewhat by an occasional fine. Both cities have been growing, and the mail-pouch service is being extended considerably. It has been found, however, that although the service has extended several miles further, and the amount of mail that is carried has been doubled since the beginning of the contract, no extra compensation has been received.

After considerable discussion it seemed to be the consensus of opinion that there should be some strong action taken, looking to a more equitable compensation for the carrying of mail, notwithstanding the fact that it was appreciated that this was a sort of accommodation which was naturally undertaken by a public service company.

The report of the Committee on Freight and Express Service was presented, and this was supplemented by a paper entitled "Progress to Date in Carrying Freight and Express Matter by Electric Roads—Some Mistakes That Have Been Made and Their Remedy," which was prepared by C. V. Wood. The report and paper were read by G. W. Parker.

The discussion was opened by E. H. Hyman, general manager of the Cleveland Traction Company. Mr. Hyman said that the whole question of freight and express service depends entirely upon local conditions. If either freight or express business is carried on in the right locality it can be made to earn money, but both services can not be carried on in one locality at a profit. Where one system attempts to operate both freight and express service there is always the liability of contention among the shippers and always confusion regarding the shipments.

B. E. Wilson said that if the road has terminal facilities such that it can handle car-load lots, and sidings that will hold trains of four or five cars, it should attempt to do business on a car-load basis; but where the road has small sidings and is not allowed to move ordinary box cars into a city, it is positively out of the question for it to consider car-load business.

During the discussion of this report the matter of the jurisdiction of the Interstate Commerce Commission came up with regard to the receipt and billing of freight or express from adjacent states. George R. Folds, of the West Penn Railways Company, Connellsville, Pa., stated that a ruling had been handed him by the commission which indicated that if the company handled any traffic which originated outside of the state, the company was under the jurisdiction of the Interstate Commerce Commission, and must comply with its regulations. It would appear that this ruling took a very broad view of the situation, including passengers, express and freight.

H. A. Nicholl, of the Indiana Union Traction Company, stated that the system handles general merchandise in less than car-load lots. In a few instances car-load lots are handled, mainly in the shape of live stock. All of the freight cars are operated as extra trains, and no attempt is made to schedule these trains. Most of the freight business is handled at night, so as to avoid the congestion of the road during the business hours of the day. At the larger terminals the company has its own freight houses and ample side tracks. These are in charge of salaried freight agents, and at the smaller stations the freight is handled jointly with the passenger. Commissions are paid to the agents for this purpose. The company has a well-organized freight department, consisting of a general freight agent and two division freight agents. These men not only solicit business, but take care of the filing of the tariffs, with general oversight of the whole business. The company does not interchange freight with the steam roads. It does, however, with other electric systems. In some instances it operates through trains over other electric lines. The earnings per car per day average about $60. The freight business is operated on a fifty-five per cent basis, and the company earns about four to five cents per mile. The freight business represents about eight per cent of the gross receipts. The company charges to its freight account about every conceivable thing it thinks belongs to the freight department.

In respect to express, the company operates a merchants' despatch, which resembles, along practical lines, express business. For this service a rate of one and one-half times the first-class freight rate is charged. The company does not have a pick-up or delivery business, and it appears that the express business does not interfere with the freight business in any way.

The discussion of the Interstate Commerce Commission rulings was again taken up, several members pointing out the necessity of taking issue with some of these rulings.

P. P. Crafts discussed the experience of the Iowa & Illinois Railway Company with regard to its express and freight business. The company has a contract with the American Express Company on a tonnage basis, and hauls all of the American Express business originating on the Chicago & Northwestern Railway Company into Clinton. The company does not permit the express company to do any local business between the railway company's termini or along the line. A compensation of twenty cents per 100 pounds is received. No compensation is received for articles such as are carried in messengers' safes, nor for currency handled.

With regard to freight business, the company handles about three and one-half car-loads of freight per day. About fifty per cent of this is local, and the balance is part of through shipments which go west on the Chicago & Northwestern from Clinton.

The symposium on the "Possibilities of a Well-Conducted Publicity Department" was taken up, Mr. Warnock presiding.

Mr. Warnock pointed out the conditions which had led to the formation of publicity bureaus by the public service corporations, and emphasized the considerable good which was being effected by having men properly equipped to handle news in such a way that it would be put into the daily press without perversion, and would form the best means of putting to rest the generally unfavorably conception which the ordinary citizen has of the railway company.

The first paper on this subject was presented by Charles E. Flagg, of the department of publicity of the Inland Empire System, Spokane, Wash.

Mr. Flagg considers that the possibilities of a railway's department of publicity depend largely upon the natural environments. The city of Spokane has something over 100,000 population, with five transcontinental railroads, 104 miles of city traction lines, and 200 miles of interurban electric railroads. The Inland Empire System, which now has 225 miles in operation, began less than five years ago as the Spokane Traction Company, city lines, and the Coeur d'Alene & Spokane Railway, interurban lines, between Spokane, Wash., and Coeur d'Alene, Ida. In the matter of publicity, the company uses the daily newspapers, illustrated folders, official time tables and maps, enlarged photos, billboards, street cars, post cards, souvenirs and any other means that appeals to the publicity department as opportune and likely to bring results.

It has been found most practicable to use good-sized display spaces in the evening papers and reading notices in the morning papers. In each suburban town through which the lines pass a small display is run in the weekly newspapers, consisting of a local time table varied with announcements regarding excursion and colonists' rates to and from the East. In the preparation of folder copy, the illustrations are made as large as possible and the type matter brief and concise.

Mr. Flagg advocates picture advertising as one of the most convincing means of publicity. The best views are selected for enlarging, and these are framed and hung in depots and in good locations in public buildings. There are also complete photo albums in the general passenger and publicity departments, as well as on parlor cars.

Mr. Flagg was followed by B. R.

Stephens, of the Illinois Traction System, of Springfield, Ill.

Mr. Stephens described the publicity department of the Illinois Traction System. He believes thoroughly in the use of newspaper space for the publication of time cards and also endorsed the use of folders.

Concerning the expenditure for a publicity department, Mr. Stephens said that on steam roads, as a general rule, an allowance is made in the operating expense of two per cent of the gross passenger earnings for publicity purposes. On interurban roads it would appear that approximately one-quarter of this amount, or one-half of one per cent, is the allowance made for the purpose.

The meeting was then adjourned until Thursday morning.

THURSDAY MORNING SESSION.

The first business of the Thursday morning session was the reading of three papers on the "Possibilities of a Well-Conducted Publicity Department," by George Sabin Brush, of the Boston Elevated Railway Company; Charles W. Lamb, advertising expert, and G. H. Gall.

The discussion on these papers was opened by the reading of a communication from William A. House, president of the United Railways and Electric Company, Baltimore, Md.

Mr. House considers that a publicity department is a welcome step forward in the public service corporation. It is beginning to be realized that the best paying policy is to deal liberally and fairly with patrons and encourage a spirit of co-operation. The adoption of a liberal, progressive and generous policy, backed by a thoroughly organized and enlightened publicity department, was recommended by Mr. House as one of the surest ways to avoid the criticisms so frequently indulged in at the expense of the corporation.

E. A. Kendrick, secretary of the Matthews-Northrup Works, Buffalo, N. Y., made a brief address on the subject of advertising and printed matter.

The discussion on these papers was closed by H. A. Faulkner, passenger agent of the Boston & Northern Railroad, of Boston. Mr. Faulkner considers that it is the best policy to treat the newspapers very squarely, and if this is the practice of the corporation, much good can be secured. He described the information bureau which his company had established, which is under the direction of the passenger department and located with the other railroad offices. This information bureau is fitted up with every kind of literary information, and the attempt is made to get hold of not only what is interesting concerning the company's own system, but everything connected with a scenic effect or railroad situation outside of the New England States. The clerks are instructed to give absolutely impartial information, whether the inquiry is concerning the company's lines or competing lines. Although Mr. Faulkner is an old newspaper man and appreciates very highly their value, he does not place them first in importance for the special uses of the street railway man. He considers that the company's own cars are the best advertising medium that can be found and that as an advertising medium they should be used to the limit. In his system the division superintendents keep the publicity department informed concerning festivities occurring in any locality, and the attempt is made through dasher signs to promote travel in these directions. One of the most valuable publications of the Boston & Northern company is called the "Tri-State Tourist." Forty thousand copies of this are issued per month, and distributed at various points on the company's system in three states.

The report of the Committee on Interurban Rules was presented by J. N. Shannahan.

This report is based on the book of rules adopted at the Columbus convention in 1906. The committee has aimed to harmonize as closely as possible the codes adopted by the various associations during the past two years, and the rules include codes adopted by the Central Electric Railway Association, the New York State Street Railway Association, and the rules of the operating Indiana companies. The committee recommends that the association direct the incoming Committee on Interurban Rules to cooperate with a committee to be appointed by the Railway Signal Association in formulating a new code governing the use of semaphore signals.

It was voted to receive the communication as a progress report and that the committee be continued.

After considerable further discussion of the report it was voted to extend the authority of the present standing committee on interurban rules so that the committee might confer with various public service commissions throughout the United States, and, in its discretion, distribute copies of the rules as presented by the committee.

The report of the Committee on the Operation of Multiple-Car Trains on Interurban Roads was presented by D. F. Carver.

Owing to the lateness of the hour there was no discussion upon this report.

The reports of the Committee on Passenger Traffic and of the Committee on Rules for City Operation were received and written discussion requested.

The report of the nominating committee was presented as follows: President, C. Loomis Allen; first vice-president, R. T. Todd; second vice-president, G. L. Radcliffe; third vice-president, A. W. Warnock. Executive committee: the officers, and G. W. Parker, Detroit, Mich.; H. C. Page, Springfield, Mass.; N. W. Bolen, Newark, N. J.; H. A. Davis, Nashville, Tenn. This report was unanimously adopted and the gentlemen named declared elected.

Mr. Shannahan and Mr. Brush were named as a committee to escort Mr. Allen to the chair, and after a few remarks by the president-elect the convention stood adjourned.

Meeting of the Pittsburg Section of the American Institute of Electrical Engineers.

The regular October meeting of the Pittsburg section of the American Institute of Electrical Engineers was held in the lecture hall of the Carnegie Institute, Pittsburg, Pa., October 13.

The evening was devoted to the presentation and discussion of two original papers. The subject of the first paper was "The Oscillograph and Some of Its Uses," by H. H. Galleher, engineer of the high-tension testing laboratory of the Westinghouse Electric and Manufacturing Company, and the second one was entitled "The Testing of Large Alternating-Current Generators," by L. E. Schumacher, of the dynamo testing department of the same company. The papers were illustrated by lantern slides.

Mr. Galleher's paper dealt with the practical application of the oscillograph to everyday problems and explained its general construction, operation, adjustment and repairs.

Professor S. M. Denton, of the Carnegie Institute, supplemented Mr. Galleher's paper with a talk on the application of the oscillograph to the solving of complex problems in phase relation, and showed how essential this instrument has become in large power-transmission plants as a means of explaining perplexing phenomena. He advocated the purchase of such instruments by high-tension central stations generally.

Mr. Denton then gave an interesting description of the Irwin hot-wire oscillograph, which, he stated, gives great promise as a cheap and sufficiently accurate instrument for such purposes.

The subject was further discussed by R. P. Jackson, S. M. Kintner and A. W. Copley.

Mr. Schumacher's paper dealt particularly with the tests on the large 8,770-kilowatt, 12,000-volt, three-phase generators of the Ontario Power Company at Niagara Falls, which were tested after erection. The methods of testing and some results were given.

The paper was discussed by P. M. Lincoln, W. L. Waters, F. D. Newbury and C. Renshaw, special comment being made on the water rheostat and the use of temperature coils to ascertain temperatures in places where thermometers could not be used.

The next meeting will be held early in November, the subject being "Electricity in Mines," by George R. Wood, consulting engineer. This subject is of great interest just at present in the Pittsburg territory.

The New Haven Electrification.

William S. Murray, electrical engineer of the New York, New Haven & Hartford Railroad Company, which has been operating the Westinghouse single-phase electric railway system on a part of its lines during the last two years, in discussing its experiences with electrification, says:

"The most commercially valuable answer as to the success of electrification on the New Haven is written in the actual operating schedule in the electrification zone. The train minute delays suffered to-day by electrical operation are but a small percentage of those incurred during the period of steam operation.

"As the zone limits in our case were not a terminal proposition, the application of the direct current showed itself to be impracticable. On account of errors, always common of initiative work, the first few months' operation has been a period of interruption which has naturally been annoying both to the road and the public. To-day the delays have disappeared by the removal of their cause.

"The wisdom of the purchase of a locomotive consisting of two individual half units, the whole or half unit being operative by a single crew, has proved itself in the ability of the road to handle seventy-five per cent of traffic with half-unit locomotives, using the whole unit on the remaining twenty-five per cent of trains, whose weight demands the full drawbar. Should future requirements see the advantage of extension of electrification east of Stamford, the system is designedly applicable.

"As to the saving in cost of operation as compared with steam, I would state that operation to-day has not been a sufficient length of time to make this comparison. It may be interesting to note, however, that by exhaustive investigation I have found that one pound of coal burned under the boilers of our central station produces twice the drawbar obtained by one pound of coal burned in the fire boxes of the steam locomotive, or in other words, the fuel bill for electric traction is one-half of that required for steam traction. Other economies will arrive in the low cost of maintenance and repairs of the electric locomotive as against steam locomotives.

"The density of traffic is, of course, the paramount feature as to the savings to be effected by electrification. It is not to be forgotten that, in electrifying, interest, depreciation, insurance and taxes follow closely on the heels of the capital investment in equipment and material necessary to electric operation. The heavier the traffic, the greater will be the economies derived from the two above-mentioned sources.

"It is quite conceivable that the heavy ton-mileage in freight and passenger service on the Atlantic coast line roads will effect savings sufficient to cover the above-mentioned fixed charges on the investment necessary to their electrification.

"The greatest value to be experienced by electrification will be in the tremendously increased traffic capacity of the present track mileages, due to the facility electricity offers in making rapid main line and yard train movement, or, stated in another way, it is thus immediately seen that electrification will permit a tremendous increase of traffic without an increase of track mileage, and thus roads which are up against the requirement of handling their congested traffic by laying new tracks, which, of course, is a most expensive procedure on account of right-of-way difficulties, will be led into providing an equal capacity by electrification of the old trackage."

American Institute of Electrical Engineers' Papers.

To the Editor of the Electrical Review:

About a year or so ago I read an editorial in the Electrical Review regarding the papers read before the American Institute of Electrical Engineers. It was suggested that the number of papers be cut down to one per meeting, together with prepared discussion on same. By such adoption the Papers Committee would have a wider range of choice to select the best papers available, which, in turn, would mean that the authors would be better prepared for questions and answers, and papers would not be read at all which were presented with the apology that they were prepared at the eleventh hour.

It is a great pleasure to note that in this month's proceedings of the American Institute of Electrical Engineers, "the Meetings and Papers Committees propose to accept but one paper for each meeting during the present season, to be followed by prepared discussion."

Supplementary to same, I respectfully suggest the following two points for the assumed benefit of the engineering profession in general:

First, that the Committee on Papers confer with engineers, whether members or not, and secure by invitation, in concrete form, compact researches and studies on subjects covering a wide range, with numerous comparisons drawn.

Second, to invite engineers who are up to date in European practice to present papers on modern European subjects.

Practically all the papers read before the American Institute of Electrical Engineers are of domestic practice; my observation during seven years' residence in the United States is that many of these papers contain what are apparently basic features, but which have existed in Europe for a number of years in every-day practice.

In connection with my latter suggestion it must be borne in mind that the early familiarization with European ingenuities greatly facilitates domestic problems. Further, as an example, permit me to call attention to the fact that the papers presented to the Verein Deutscher Ingenieure (German Society of Engineers) comprise about twenty per cent of foreign, especially American, topics. In addition it is recognized abroad, also to a certain extent in this country, that the European engineer reads more American technical literature than *vice versa*.

What we need is a more frequent and friendly interchange of ideas whereby we can profit from one another. The advantage is fully recognized by competent engineers who make studies abroad to ascertain conditions there. That the argument is not one-sided is shown also by the trips of foreign commissions sent here to study our methods.

Frank Koester.

New York, October 20.

Hudson River Electric Power Reorganization.

The reorganizing committee which has undertaken to readjust the affairs of the Hudson River Electric Power Company in order to meet its financial obligations, has announced the terms of the agreement under which the holders of the $5,000,000 of bonds, whose interest has been in default since August 1, are invited to submit their holdings for participation in the reorganizing plan which is to be announced later.

The bondholders' committee in its original announcement provided that "if the final plan which the committee proposes to submit does not meet with their approval, said depositors may withdraw their bonds within ten days after written notice that fifty-one per cent in face value of the depositors have adopted the plan."

THE KERR MILLS OF THE AMERICAN THREAD COMPANY, FALL RIVER, MASS.

A DESCRIPTION OF THE NEW STEAM TURBINE POWER PLANT.

In the early part of 1907 the American Thread Company decided to make an addition to its plant at Fall River. The old plant consisted of a spinning and twisting mill, dye and gassing house. The power for the main mill was derived from a double tandem-compound engine of about 1,600 indicated horse-power; and the dye and gassing houses were driven by small engines, the power from these and the main engine being distributed throughout the various mills by belts and shafting.

It was decided to drive the new mill electrically, principally on account of the probability that, as the business increased, various additions would have to be made, and the electrical drive lends itself particularly well to this end.

The building of the new plant necessitated the complete rearrangement of the machinery in the old main mill.

It was first proposed to merely make a new arrangement of the shafts and belts, and at some future time—when it became necessary to install a new engine—to change to electrical drive. An accident, which might have had serious results, occurred to the main engine before this plan had been carried out, which decided the management to abandon the engine and immediately install electric drive, not only in the new mill but in the old mill as well. The new power-house described in this article was, therefore, designed to furnish power for the complete plant and is arranged so that it can be conveniently enlarged to care for future power requirements.

The power-house is located on South Watuppa Pond. The tracks of the New York, New Haven & Hartford Railroad run between the power-house and the pond, cutting off a small body of water from the main pond. Connection was made with the main pond at two points, the water being brought into the power-house through one of these connections and a trench, and the water from the condensers flowing into the small pond and thence under the railroad, through the other connection, into the main pond. These connections were placed some distance apart so that the used water would have no tendency to return to the power-house.

The power-house building consists of a turbine room, forty-three feet by fifty-six feet, and a boiler room, fifty-eight feet by 132 feet. The building is of brick with concrete floors and roofs. The boiler room contains twelve horizontal tubular boilers built by the Bigelow Company, of New Haven, Ct., each rated at 200 horse-power. These boilers are hung from beam supports and are brick set, the setting being arranged so that superheaters can be installed in the rear end of the setting. Three Foster superheaters have been installed for the purpose of testing their durability and efficiency. The gases from each battery of six boilers pass through a flue to a Green fuel economizer and thence to the chimney. The flue back of each battery is arranged so that the gases can either pass to the chimney or through the economizers.

All of the boilers are arranged for burning low grades of fuel and are equipped with "Parsons" blowers and arrangement of setting.

A Warren Webster open feed-water heater and purifier is located at the end of the boiler room next to the turbine room.

Two skylights are placed in the roof of the boiler room, one over the firing space and one over the tops of the boilers

The wall opposite the front of the boilers and back of the firing space is made of galvanized iron, as any future addition to this boiler room will be a duplication of the present layout, the new boilers facing the present ones.

The boiler-room floor is level with the yard. Coal will be brought from the storage piles by a conveyer system and dropped in front of the boilers.

The steam piping is arranged so that superheated or saturated steam can be supplied to the turbines or to the auxiliaries, either separately or in conjunction. This arrangement was made primarily for use in testing the efficiency of the different types of apparatus.

The feed water is delivered to the open heater and purifier and is then pumped to the boilers. The feed-water main is of cast iron and so arranged that water can be supplied either from the pond or from the heater and purifier, and delivered directly to the boilers or through the economizer.

The drips from all of the high-pressure steam mains are collected at one point and from there returned to the boilers by the Holly return system.

The turbine room has two floors, but the upper floor where the turbines are located does not extend over the space occupied by the pumps. This space was left open so that the traveling crane, which is of ten tons' capacity and built by the Northern Engineering Company, could be utilized in installing and repairing the auxiliaries as well as the turbines.

The turbine room contains two 1,500-kilowatt Allis-Chalmers alternating-current, turbo-generators; two General Electric seventy-five-kilowatt, direct-current, turbo-generator exciters, and a General Electric switchboard. This apparatus is located upon the upper-floor level.

Incorporated in the main turbines are the various patented features controlled by the builder, the Allis-Chalmers Company, among which may be mentioned channel-shaped shrouds protecting the ends of the blading from injury; machine-cut slots in the foundation rings insuring accurate spacing of the blades; a method of fastening the latter which effectually prevents them from working loose, and improved balance pistons. Other details of special interest will be mentioned briefly under the subjects to which they belong.

The turbines operate at 1,800 revolutions per minute, with a steam pressure of 150 pounds at the throttle, dry saturated, and a vacuum of twenty-eight inches of mercury referred to thirty inches barometer at the exhaust nozzle. Large temporary overload capacity has been provided for in the design of these machines; high efficiency is maintained, and close regulation secured, even under the most unfavorable operating conditions.

The bedplate is divided into two parts, one carrying the low-pressure end of the turbine. The turbine is secured to the former, while the latter is provided with guides which permit the end of the turbine to slide back and forth with differences of expansion caused by varying temperature, at the same time maintaining the alignment.

The "Bulkley" condensers are located outside the building.

The speed of each turbine is regulated within close limits by a governor driven from the shaft through cut gears working in an oil bath. This governor, by means of a relay operates a balanced throttle valve. The entire mechanism is so proportioned as to respond at once to variation of load, but its sensitiveness is kept within such bounds as to secure the best results in the parallel operation of the two turbo-generators in this station. The governors can be adjusted for speed while the turbines are running, thereby facilitating the synchronizing of the generators and dividing the load as may be desired. In order to provide for any possible accidental derangement of the main governing mechanism, there is an entirely separate safety or over-speed governor. This governor is driven directly by the turbine shaft without the intervention of gearing, and is so arranged and adjusted that if the turbines should reach a predetermined speed above that for which the main governor is set, the safety governor will come into action and trip a valve, shutting off the steam and stopping the turbine.

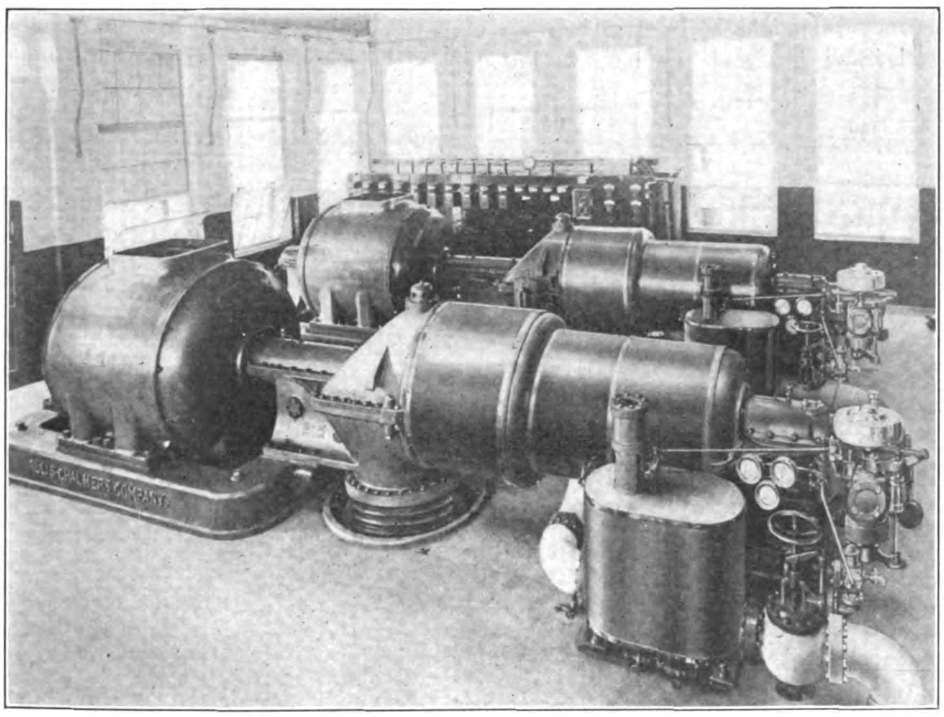
The bearings are of the self-adjusting ball and socket pattern, especially designed for high speed.

The lubrication of the four bearings, two for the turbine and two for the generator, is effected by supplying an abundance of oil to the middle of each bearing by means of a small cycloidal pump driven from the turbine shaft, and allowing it to flow out at the ends. The oil is passed through a tubular cooler with water circulation, and pumped back to the bearings.

It is not necessary to supply the bearings with oil under pressure, but only at a head sufficient to enable it to run to and through the bearings, this head never exceeding a few feet. No oil of any kind is used in the interior of the machines nor in the glands through which their shafts pass. Low oil alarms have been provided for the turbines.

The hot parts of each turbine up to the exhaust chamber are covered with an ample thickness of non-conducting material and lagged with planished steel, so applied that it may be easily removed. The non-conducting covering is also removable at the cylinder joint to facilitate the opening of the turbine for examination.

Between the turbine and its generator a special type of flexible coupling is used to provide for any slight inequality in the alignment of the bearings, to permit axial adjustment of the turbine spindle, and to allow for difference in expansion. This coupling is so made that it can be readily disconnected for the removal of the turbine spindle or of the revolving field of the generator. Provision is made for ample lubrication of the adjoining faces of the coupling.



Two 1,500-Kilowatt Allis-Chalmers Steam Turbines and Generators in the Kerr Mills of the American Thread Company.

The revolving-field alternators driven by these turbines are of the Allis-Chalmers Company's standard type, designed for high efficiency and safe operation at high peripheral speeds. Some of the principal advantages embodied in their construction are summarized as follows:

The field core is built up of steel discs, each in one piece, giving high magnetic permeability and great strength. Coils are placed in radial slots, thereby avoiding side pressure on slot insulation and the complex stresses resulting from centrifugal force, which, in these rotors, act normal to the flat surface of the strip windings. Bronze wedges hold the coils firmly in the slots, making the surface of the rotor a smooth cylinder, reducing windage losses and insuring quick operation. The end connections are securely held by chrome-nickel steel rings.

The stator is completely enclosed, eliminating noise of operation. Coils were completely wound and insulated before being placed on the core, thus obviating the risk of defective insulation. Stator windings are placed in open slots, rendering the coils readily removable. End connections are firmly braced, preventing deformation of coils in case of short-circuit.

For the purpose of obtaining adequate ventilation and for muffling the noise produced by the circulation of the air, the turbo-generators are enclosed in such a manner that the air is taken in at the ends through fans mounted on the rotor shaft which discharge it over the end connections of the armature coils into the bottom of the machine, whence it passes through the ventilating ducts of the core to an opening at the top. This patented system of ventilation is most efficient.

On the lower floor of the turbine room are two engine-driven Lawrence centrifugal pumps for condensing water, one Blake 1,000-gallon Underwriters fire pump, one electrically driven Deane triplex power pump for sanitary water for the mills, one Fairbanks-Morse duplex steam-tank pump for water supply to the heater and purifier, one engine-driven Deane triplex power pump and one Heisler duplex steam pump for boiler-feeding purposes.

The engine-driven triplex boiler-feed pump is arranged so that it is automatically controlled by the opening and closing of the boiler feed valves, a constant pressure being maintained on the feed line. Any lowering or raising of this pressure causes the pump to run faster or slower according to the demand for water.

The switchboard is located on the same floor as the turbines and consists of two panels controlling the exciters, two panels for the main turbo-generators, one panel for a Tirrill regulator, seven panels for the power circuits and one panel connected to the lighting circuits.

This switchboard has a complete equipment of instruments and all switches are oil-immersed, except the main generator switches, which are solenoid-operated circuit-breakers. The feeder mains are carried under ground to each mill through fibre conduits.

Taken all in all, this plant is very complete, being so designed as to secure both maximum economy and low operating costs. The plans for it were made and its construction superintended by S. M. Green, consulting engineer, of Holyoke, Mass.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

System of Simultaneous Telegraphy and Telephony Over Telegraph Wires.

Experiments made by Aurio Carletti under the auspices of the Italian Telegraph Department between Caserta and Piedimonti are here described. The work was undertaken for the purpose of testing the Perego separator of simultaneous telegraphic and telephonic messages, but the device was found unsuitable for use between any two subscribers and could only be employed between the two offices at the extreme ends of the line. Better results were obtained with the arrangement shown herewith. The telegraph currents are separated from the telephone currents by means of a condenser C; T is a telephone transformer of the kind usually employed for connecting a single-wire to a double-wire line; *j* is the jack at the switchboard. In order to make the variable period of the telegraph currents slower and deaden the noise produced by them in the telephone receiver the well-known arrangement of Van Rysselgerghe was employed, which consists chiefly of a coil *g* with strong self-induction connected in series with the line, and of a condenser C of two microfarads in multiple with the line. The coil *g* also serves for resisting the leakage of the telephone currents through the telegraph apparatus, the coil acting in this case as an impedance against the high-frequency telephone currents, so that they will pass preferably through the condenser C and the secondary of the transformer T. To the telegraphic currents, on the other hand, which are continuous, the coil *g* offers only its ohmic resistance. This arrangement gave good results and permitted communication from Piedimonti with subscribers in Caserta, Naples and Rome. However, there still was a considerable leakage of current through the telegraph instrument, which was detrimental. One way of reducing this leakage was to increase the impedance of *g*, but that would have disturbed the telegraph service too much. Furthermore, the impedance depends chiefly on the frequency, and consequently the leakage of the telephone currents will not be equal for all harmonics: it will be greater for the lower sounds and smaller for the higher ones, and thus the voice will be distorted. Another cause of serious disturbance is the intermittent exclusion of the telegraph receiving circuit. In the receiving position the electromagnet of the telegraph instrument will be in series with the coil *g* and add its impedance thereto; in the transmitting position the line is connected to the battery and the telephone currents can leak away freely through the battery, and thus the telephone current will be alternately weak and strong. To remove this difficulty an impedance coil might be inserted between the telegraph key and the battery, but this arrangement would be too complicated and would greatly increase the resistance and inductance of the telegraph circuit. A simpler artifice, which gives the same results, is to put the telegraph receiver in series with the line. In this case the Morse receiver acts also as an impedance, and therefore the coil *g* may be eliminated. An arrangement which has not yet been sufficiently tested, but which might completely remove all the difficulties referred to is to put the transformer T in series with the telegraph line. In this manner all the telephone current is utilized, because it passes entirely through the transformer T, while in the arrangement shown herewith only a part of it passes through the transformer and the remainder escapes at A through the telegraph receiving group. The arrangements described are not suitable when the telegraph wires are disturbed by industrial currents.—*Abstracted and translated from L'Elletricista (Rome), September 1.*

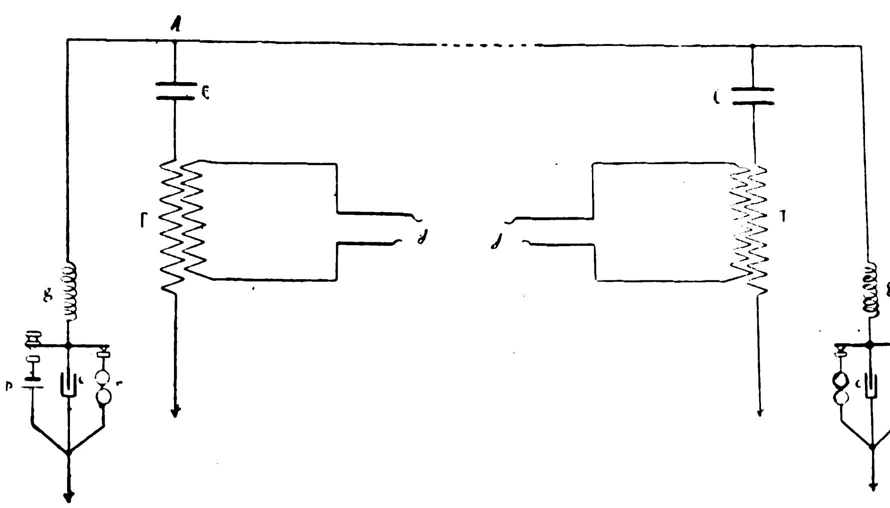


Diagram of Circuit for Simultaneous Telephony and Telegraphy.

Effect of Wireless Telegraph Transmission on a Telephone System.

In the north of England a wireless telegraph station recently caused considerable trouble to the local telephone exchange. The telephone circuit was provided originally with an aerial line, two spans of which came within the staying ground of the wireless mast, which is 225 feet high. These wires were not adjacent to or parallel with any leads or wires of the radiotelegraph system. The telephone wires were twisted in the usual way, and immediately outside the station grounds were connected with wires for other local subscribers. Originally the telephone circuit was provided with a battery at the station for signaling purposes, both wires being used for signaling as well as for speaking. At the wireless station the spark system was in use, absorbing several kilowatts of energy. Not only was the speaking difficult from the telephone station itself, but other circuits traversing the same routes were seriously interfered with and false rings were received from time to time by various subscribers, and sparking was also observed at the telephone exchange. Arrangements were made to substitute cable for the aerial line on the station grounds. Meanwhile the local telephone system was changed over to common battery working. This greatly accentuated the difficulty, due, no doubt, to the fact that one of the wires was normally joined to earth for signaling purposes. The disturbance to speaking was not increased, but the heat coils at the exchange were continually being burned out. The lightning protectors were also affected. A lead-covered cable was buried in the ground and terminated a few yards from the hut by means of unsheathed cable. This reduced the disturbance considerably but did not entirely overcome it. Finally the lead-covered cable had to be extended into the hut and terminated close to the telephone instrument before the difficulty was entirely overcome. At the wireless station an arc system was installed, but no difficulty was experienced with the undue oscillations. —*Abstracted from the Post Office Electrical Engineers' Journal (London), October.*

The Arc Between Identical Electrodes as a Rectifier.

Dr. Johann Sahulka describes some investigations of the rectifying effect of an alternating-current electric arc. In his previous writings he has pointed out that such an effect takes place not only in an arc between dissimilar electrodes, but also, though in a smaller degree, between electrodes of identical material, as carbon, for instance, if they do not have the same dimension or position. With an arc between two equally thick carbons in a vertical position the lower one is always electrified positively toward the upper one, so that outside of the arc a direct current flows in the direction from the lower to the upper one. The difference of potential of the rectified current depends on the intensity of the alternating current; with homogeneous carbon rods, seven millimetres in diameter, it amounted to a maximum of 2.8 volts. If the alternating-current arc is produced between two electrodes of different thicknesses the thinner carbon rod is always electrified positively toward the thicker one; the potential of the rectified current depends on the current intensity and position of the carbons. The alternating-current arc between two identical electrodes is always predominatingly negative toward both electrodes, so that in a branch circuit between either one of the electrodes and a test rod inserted into the arc a strong direct current is obtained. The manifestation of a direct current in an alternating-current arc between two identical electrodes is explained by the unequal temperature of the electrodes. The chief condition for the maintenance of an arc is that the cathode has a high temperature and that the space surrounding it is conducting. If one of two carbon electrodes is hotter than the other, therefore, the current flows through the arc from the colder to the hotter electrode more easily than in the opposite direction, and the corresponding half waves of the alternating current are stronger for this reason. It is evident that this rectifying effect will be increased, if the temperature difference of the two electrodes is made as great as possible, as by cooling one electrode or establishing favorable cooling conditions. If an arc is produced between a carbon rod and a carbon plate, a direct current must flow through the arc from the rod to the plate. The rectifying effect of the arc increases with its length, and it would be expected that it might be lengthened to such an extent as to allow only the passage of those half waves of the alternating current flowing from the carbon plate to the rod. But if an attempt is made to approach this extreme condition, the arc becomes unsteady and breaks off. It is easy, however, to obtain a direct current equal to about one-seventh of the intensity of the entire current. In order to increase the temperature difference still more, he has produced an arc between a carbon rod and a rotating disc. The highest proportion of direct current obtained was thirty-one per cent of the total current consumed, which result is unfavorable. The efficiency might possibly be increased by providing for a better cooling of the disc or by carrying out the experiment in a vacuum. —*Abstracted and translated from Elektrotechnische Zeitschrift (Berlin), October* 1.

Explosion Gas Turbine or Combustion Gas Turbine.

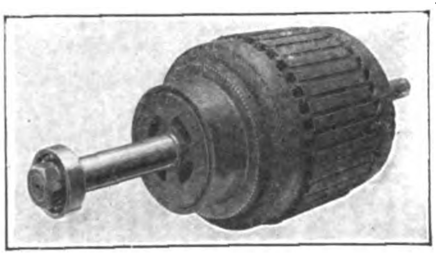
The question which of these two types of turbine offers the greater practical possibilities seems important enough to deserve to be determined by calculation, says Dr. Phil. Wegner-Dallwitz in this article. Whenever reference is made to a gas turbine, it is usually a combustion turbine, although published calculations show that, with the technical means at present available for its construction, the practical possibilities of this engine are very poor, while an explosion turbine can already be constructed which, though its heat economy may not be brilliant, can compete with the steam turbine, particularly in view of its greater simplicity (absence of the steam boiler). In the present article the combustion turbine is dealt with. The operation of such an engine is briefly as follows: Air and gas of a pressure equal to about that of the atmosphere and also of about the same temperature are compressed by pumps to a higher pressure, with an eventual rise in temperature, and are pressed into a combustion chamber, where the gas is burned by aid of the air in such measure as it is delivered by the pump, but so that the pressure in the chamber is not changed by the combustion process and the resulting heat and expansion. The inflow of gas is offset by an equally great outflow. The combustion raises the temperature of the chamber contents and causes them to expand through Laval nozzles to a lower pressure and temperature, whereby they attain a certain velocity with which they flow into any desired turbine system and perform work. The practicability of the combustion gas turbine is largely dependent on the efficiency of the compressor. It seems that only a turbine compressor, which rotates on the same shaft as the gas turbine, can be considered. A compressor of this kind by Parsons has been reported, which is said to compress gases to 1.4 atmospheres with an efficiency of sixty per cent. But it is not indicated whether this figure refers to adiabatic or isothermal compression. In technical circles generally the statements concerning this high efficiency are regarded skeptically. But even assuming this high compressor efficiency to be possible, and taking into account the thermal efficiency of the combustion process, the author reaches the following conclusions: If we are limited to adiabatic compression, the thermal efficiency of the combustion gas turbine at low pressures will be extremely small, and even at the high combustion pressure of fifty atmospheres it will be only 3.4 per cent in spite of the high compressor efficiency. If it should become possible to approach the compression curve to that of the isothermal, then the efficiency will rise to utilizable values at the higher combustion pressures. With a pressure of ten atmospheres in the combustion chamber and isothermal compression the absolute efficiency will be twenty-one per cent. Such a turbine would, therefore, be capable of competing with other engines, that is, if the compression could be effected with an efficiency of sixty per cent. If we figure only with the Parsons compressor under the assumption that the efficiency of sixty per cent really refers to isothermal compression, a combustion turbine could be constructed that would work with a thermal efficiency of three to eight per cent. Such a turbine could not be put on the market.—*Abstracted and translated from Die Turbine (Berlin), September* 20.

INDUSTRIAL SECTION

ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

Lincoln Variable-Speed Motors.

Considerable success has been attained in shop as well as in electrical results in the last two years by the variable-speed motor of the armature-shifting type made by the Lincoln Motor Works Company, of Cleveland, Ohio, formerly the Lincoln Electric Manufacturing Company. This motor, when it was first put on the market, was described in the September 15, 1906, issue of this paper. Since then the motor has proved itself especially useful for the individual driving of machine tools throughout various machine shops in the United States and Canada. It is also used extensively in the machine shops of the United States Navy. The motor is conservatively rated, as the standard motor without undergoing any change meets the requirements of the United States Army and Navy.



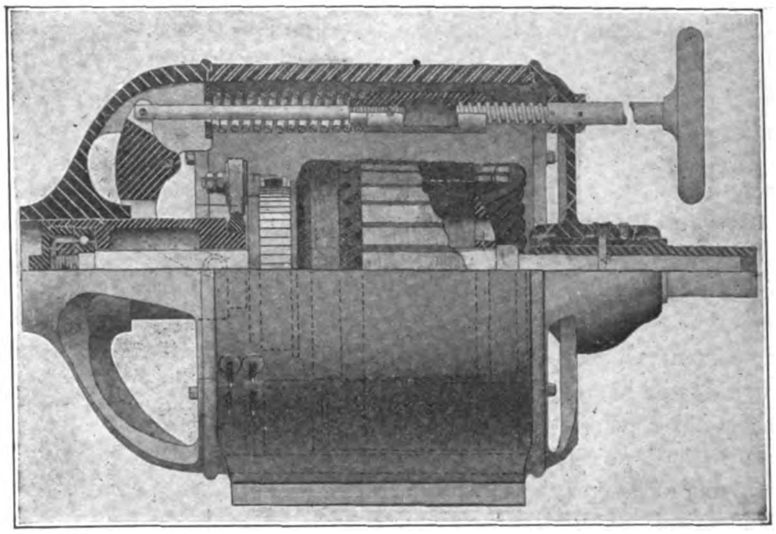
ARMATURE OF LINCOLN VARIABLE-SPEED MOTOR.

The accompanying cross-section shows the principal parts and working mechanism of the Lincoln variable-speed motors. It may be noted that by turning the hand wheel the slightly cone-shaped armature is withdrawn laterally away from the tapered field which at the same time gradually increases the air-gap, decreases the magnetic flux, and increases the speed.

Sparkless commutation is provided by the use of a commutating pole. The Hess-Bright bearing on the commutating end of the armature provides for both the radial bearing and end thrust due to the slight magnetic pull of the armature back toward the field. The pinion or pulley is carried on the sleeve which is the bearing and into which the armature shaft is keyed so the end movement occurs only in the armature shaft.

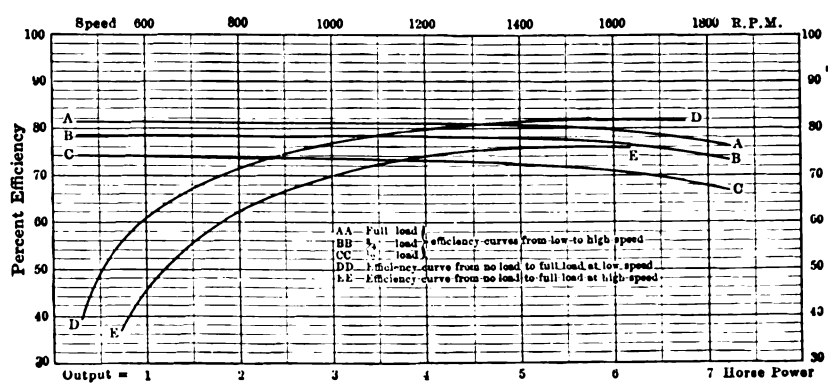
The principal features claimed for the Lincoln variable-speed motors are as follows:

No electrical controller is required. The speed variation is obtained by the simple mechanical device of shifting the armature. The motor is wired up and installed on a regular two-wire circuit in the same manner as any direct-current, shunt-wound, constant-speed motor. The motor is reversible and will run with like results in either direction. Ranges in speed as high as 1 to 10 are practicable. An infinite number of speeds can be obtained at will between the minimum and maximum speed limits of the motor, the speed change being smooth, continuous and gradual. The motor will develop its full rated capacity at all speeds, that is, with constant input the torque varies inversely as the speed, giving constant output. There is no decrease in capacity as the speed decreases. When set for any given speed the motor maintains a constant speed under varying load. In fact, the drop in speed from no load to full load at any speed is exceedingly small, comparing with the best constant-speed motor practice. By the use of special commutating poles, sparkless commutation is obtained to fifty per cent overload when running at any speed in either direction. By the use of steel frames and economical design, a light and compact motor is obtained for a given horse-power rating and efficiency.



SECTIONAL VIEW OF LINCOLN VARIABLE-SPEED MOTOR.

One of the special advantages of the Lincoln variable-speed motors which appeals to foremen and superintendents of machine shops is that if a machine tool is set for a certain speed and the operator stops the machine for calipering, on starting up again, he obtains his original cutting speed.



EFFICIENCY CURVE OF LINCOLN VARIABLE-SPEED MOTOR.

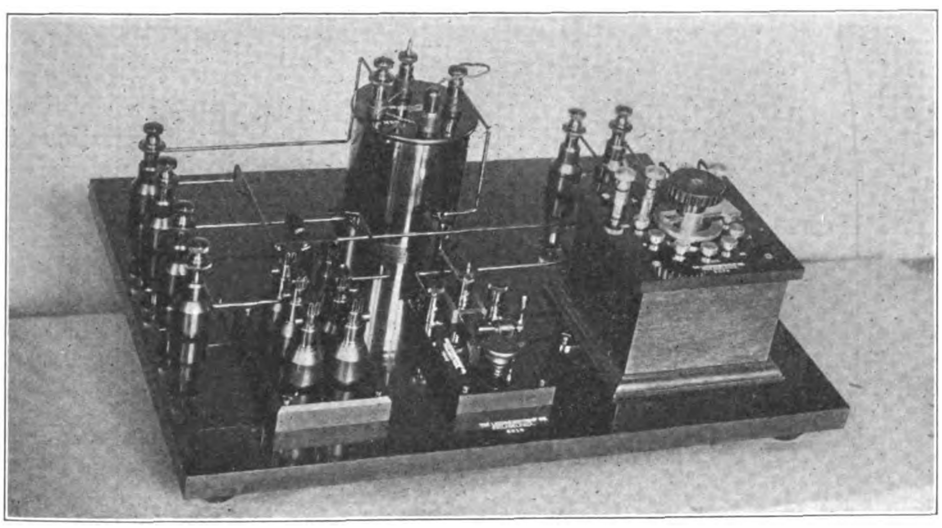
Factory Cable-Testing Apparatus.

The greater the experience of a manufacturer in insulation testing, the more will be the stress which he lays on the complete insulation of all parts of the equipment with which his product is measured. The touch of a damp hand at some critical point, a film of moisture on a hard-rubber surface, or a transient ground on a nearby lighting circuit, may introduce costly errors in the readings of the apparatus by which the quality of his product is gauged.

In maintenance tests, which must necessarily be performed in the field, portability is an absolute necessity in the testing apparatus, and, to a certain degree, the insulation of the various parts of that apparatus from each other and from ground must be sacrificed to secure this primal requisite. In factory measurements, where the testing apparatus is permanently located, it is most distinctly advisable that no precaution be neglected which may guard against the effect of transient grounds, so dangerous because so intangible. It is best to mount the individual instruments of such a set so as to secure for them ample insulation, and then to make their connections entirely visible, and open to frequent inspection. This is best accomplished by running heavy copper wire through the air, making direct connections between the instruments.

The best practice to-day avoids corrugated posts and substitutes the petticoated type. Hard rubber under the action of light deteriorates, owing to the slow conversion of the sulphur in the rubber to sulphuric acid, producing a conducting film over the surface. The petticoated post not only increases the length of the insulating surface, without a corresponding increase in the height of the post, but has the further advantage that in it almost two-thirds of the insulating service is shielded from light, moisture and dirt.

The Leeds & Northrup Company, of Philadelphia, Pa., is making up to order testing outfits comprising high sensibility galvanometer, Ayrton shunt, tenth megohm resistance, standard condenser, and necessary switches and keys. These are mounted, as described and illustrated herewith, on a highly polished base of hard rubber, which is supported on rubber insulators. All connections are polished nickel plate, and contribute to the handsome appearance of the set.

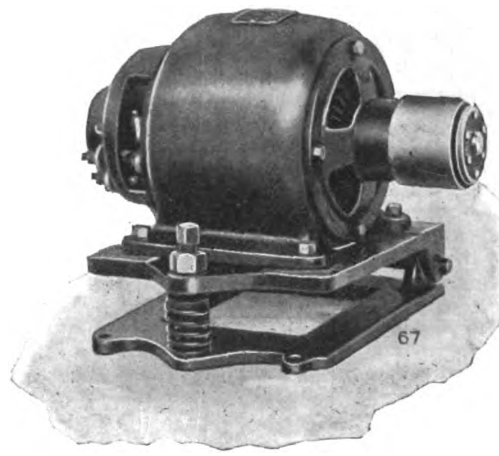


Leeds & Northrup P-83 Testing Set.

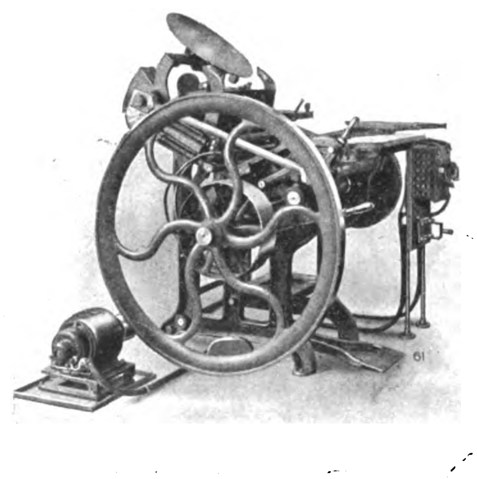
Friction Drive for Printing Presses.

The advantages of electric motor drive for printing presses have become so well known that it is unnecessary to comment upon them. At the present time there is hardly a printing plant of any size that is not driven by individual motors. Many of these, however, still use belts to connect the motors with the various presses.

There are certain classes of light machinery where belts are objectionable, owing to danger to the machine operators and the dirt which is necessarily thrown off. This is particularly the case in printing plants. Here it is very important that there shall be a minimum of dirt in the atmosphere. Compactness of the equipment is also important, as the presses must be capable of arrangement with special reference to light. In driving small printing presses a further objection arises. Presses are seldom run at a higher speed than 200 revolutions per minute, while the small size of motor required is usually built for speeds above 1,000 and even as high as 1,600. This would necessitate using a belt reduction of 5 to 1, or greater; or else a special low speed motor, with higher cost for the same power. When the motor is placed close to the driving wheel of the press, a condition required in printing shops, unless a special motor is used this large reduction means driving a very large pulley from a very small one, which can not be done satisfactorily with belt drive, even with a belt-tightening idler. The idler itself is objectionable, owing to the power which it wastes when made sufficiently tight to be effective.



Motor Equipped with Spring Base for Friction Driving.



Motor with Spring Base Applied to Printing Press.

For these reasons friction drive was adopted several years ago. This works satisfactorily as long as the friction wheel on the motor remains in contact with the driving wheel of the press, but requires considerable attention when the rigid form of motor base is used. Besides, the large flywheel on the standard makes of printing presses seldom runs true, which allows the motor to slip during part of each revolution of the flywheel. To overcome these objections the

Crocker-Wheeler Company, of Ampere, N. J., has devised the spring-base attachment shown in the accompanying illustrations. The motor is mounted on a base supported at one end with a hinge and at the other end by a heavy steel spring. An adjusting screw and locknut are provided so that the spring may be adjusted to any desired tension. The friction wheel of the motor is applied directly to the flywheel of the press. Any eccentricity of the flywheel is taken up by the spring in the motor base, so that the friction wheel makes positive contact throughout the whole revolution of the flywheel.

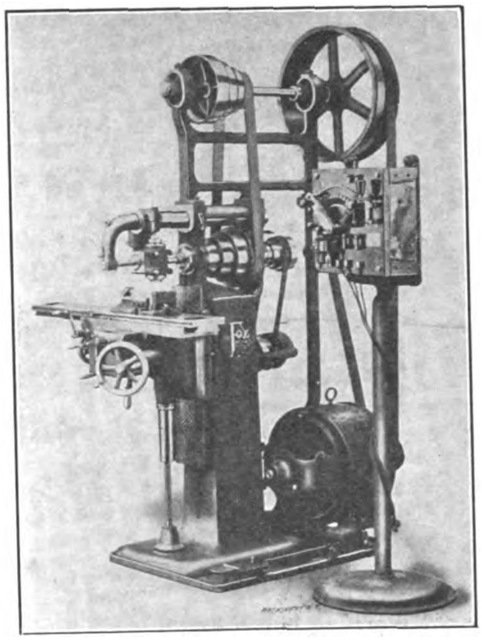
This arrangement permits the use of a high-speed motor, and therefore one of small size and low cost, and makes a very compact equipment. It enables the presses to be placed close together and very close to windows, a very important consideration. The switch and speed regulator are conveniently mounted on a stand or under the feeding shelf near the feeder's right hand, which puts the speed of the press under instant control. The absence of belts adds considerably to the cleanliness of the plant and removes the expense of furnishing new belts occasionally. There is also no belt tightening required, as the spring base, once adjusted, will take up the wear of the friction wheel almost indefinitely.

A large number of motors with spring-base attachments have been recently installed by the Crocker-Wheeler Company in printing plants and the demand for them has become so great that the bases are carried in stock for all of their form L motors from one-quarter-horse-power to two-horse-power. These motors have been on the market a number of years and have become celebrated for their high efficiency and low maintenance cost. They are carefully designed and contain the best of materials and workmanship. They are built in sizes ranging from one-twentieth to five horse-power are of the same rugged construction as the larger machines built by the same company.

Fox Milling Machine.

The simplicity of a machine designed for a wide range of speed is well shown in the accompanying illustration where the Fox light milling machine is shown fitted with a Westinghouse type "S" direct-current motor. The specifications under which this machine was manufactured required the speed of milling spindle to be adjustable over a range of 20 to 1, namely, from twenty-one to 425 revolutions per minute. Although but sixteen speeds were called for in these specifications, and these were obtained by using back gears and speed cones of four steps, it was decided to supply an adjustable speed motor.

This motor has a speed range of 2 to 1, that is, the speed may be varied from 660 to 1,320 revolutions per minute in fourteen steps. This permits of much finer adjustments in the speed of the spindle than would be possible with a constant-speed motor. This means that the cutter may at all times be run at the maximum speed it can stand, whatever the type of work it is performing.



Fox Milling Machine.

The speed of the motor is controlled by means of field regulation, that is, the controller varies the resistance in the field circuit and the motor changes its speed accordingly. This controller is mounted on a pedestal that is independent of the motor, and may be moved somewhat and located at the most convenient point for the workman.

An interesting feature of the outfit is the method of mounting the motor on an extended sub-base which is pivoted at one side. The free end of the motor bracket is supported by the short arm of a foot lever which raises the motor and slackens the tension on the belt and allows the spindle of the machine to come to rest without waiting for the motor to stop. The motor is held in the raised position by a foot catch on the front lever. Depressing the catch allows the motor to settle and tightens the belt.

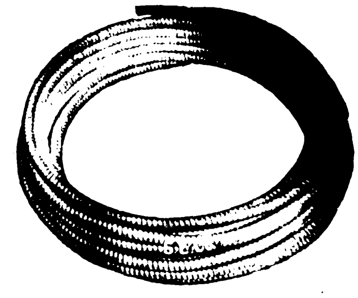
This outfit was supplied by the Fox Company to the United States Government for use at the Navy Yard at Charlestown, Mass. It is supplied with several special attachments which extend its range of work very largely, particularly adapting it for cutting small gears, milling squares, hexagons, etc., including taps and reamers, as well as a large variety of similar work.

This outfit represents the application of a motor to a standard belt-driven milling machine with a special modification of the base for mounting the motor, and shows how compact the complete outfit with a motor may be, even when the method of applying the power has not been altered. The convenience of electric drive is clearly shown, for the speed may be varied within the range of the motor by the movement of the controller handle, which the operator may locate wherever it will be most convenient to reach while at the tool.

A New Type of Conduit.

Beginning with the earliest introduction of a tube for carrying wires for electric wiring, the Sprague Electric Company, New York, has continued its efforts in the perfecting of interior conduit construction.

The latest improvement now introduced by the Sprague company is the single-strip type of conduit shown in the accompanying illustration. This differs from the well-known Greenfield double-strip type in that it is formed with a single strip of galvanized steel, interlocked and gasketed in such a manner as to be extremely serviceable in concrete construction as well as in locations liable to dampness.

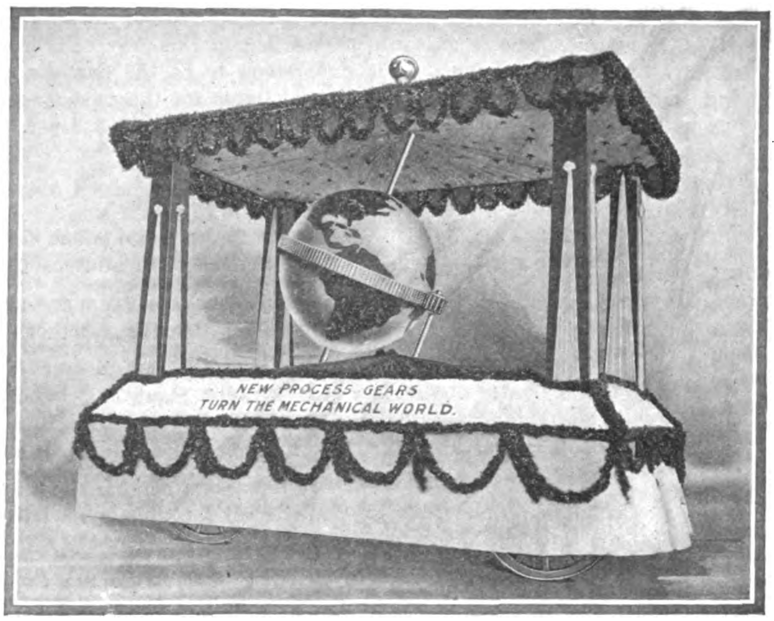


Sprague Single-Strip Conduit.

This new single-strip type of flexible steel conduit is designed particularly for fireproof building construction, but is equally suitable for new non-fireproof work or for the wiring of existing buildings. The company also manufactures a full line of fittings for use with this new type of conduit.

A Prize-Winning Machinery Float.

The accompanying illustration shows a float entered by the New Process Rawhide Company, of Syracuse, N. Y., in the Commercial float parade of the Ka-Noo-No Karnival, which is held annually in Syracuse in connection with the New York State Fair. This float won first prize in the machinery division as "the best appointed and most symbolic." The globe was supported on an upright shaft passing through the centre, and having a bearing at the top and bottom. The globe proper was about five feet in diameter, and was made of one-ply rawhide formed in two hemispheres which were attached to a large gear ring at the centre. Inside the globe there were thirty incandescent lamps, and as New Process rawhide is quite translucent, the night effect was striking. The pinion was of rawhide carried on an upright shaft with a bearing at the bottom. This pinion was rotated by chain drive under the wagon from one of the rear wheels, and imparted motion to the globe when the wagon was moved.



A Prize-Winning Machinery Float.

Electrical Supplies for the Navy Department.

The Bureau of Supplies and Accounts will open bids in Washington, D. C., on November 10 for the following electrical material: Two cabinets and panel-boards, 1,800 feet cable and 4,000 feet rubber-covered wire for delivery at Norfolk, Va.; miscellaneous cable and cable conductors, for delivery at Philadelphia, Pa.; fifty-six grammes of sheet platinum and 585 grammes of platinum wire for delivery at Brooklyn, N. Y.

Electrical Friction Tapes.

In the manufacture of insulating tapes and cloths, the Massachusetts Chemical Company, of Walpole, Mass., has year by year studied the needs of the electrical art, in the development of insulations for all kinds of electrical apparatus under all conditions of operation. Scientific research has steadily kept pace with the exacting requirements of the electrical industries.

The essentials of a first-class modern friction tape, that give it the necessary electrical and mechanical qualifications, are: Lasting quality, chemical neutrality, adhesiveness and moisture-proof quality.

First is the durability of the tape in service—its "lasting quality." It must not only have good initial adhesiveness, but must be free from all risk of drying out under the severe and repeated temperature changes to which it will be subjected, or under atmospheric conditions. When used to insulate joints in line conductors, exposure to alternating extreme heat and cold, and rain and dry weather, winds, acids or alkaline vapors, and varying mechanical strain, must not cause it to unwind, or otherwise affect the continuity and insulation of the protecting envelope that it provides. When used in the insulation of electrical machinery the heating that it gets, buried as it may be in the vitals of the windings where it is subjected for long periods to the maximum temperature attained by the machine in operation, must not deteriorate or "age" it in any way—as by partially carbonizing it—as to lower the insulation which it is depended on to give.

The material of the tape must be perfectly neutral; it must contain nothing that will attack the fabric or the impregnating insulation, or that will undergo chemical decomposition into such corroding substances. This quality is shown in practice by a test of the mechanical strength of the material, made several months after impregnating and coating it with the compound—a tape perfect in this respect showing no loss of strength after such lapse of time. Neither must there be present any substances that can corrode or deteriorate the copper over which the tape is wound.

Adhesiveness is an important feature. The experienced and discerning buyer, in deciding upon a tape that will give genuine and permanent protection to wire joints, and in all uses in the construction of electrical apparatus, looks further than to initial adhesiveness.

Moisture-proof quality is a feature that is specially required in tapes used in connection with the winding of electrical machinery. Owing to the fact that cotton absorbs moisture very readily, tapes to resist moisture must be thoroughly impregnated with the compound, and the latter must be of good quality.

The Massachusetts Chemical Company has recently begun the construction of a new addition to the Walpole factory. This extension, comprising 15,000 square feet of floor space, will be used in connection with the tape department, which has outgrown its present accommodations.

Hudson Tunnels Progress.

William McAdoo, president of the Hudson tunnel system in New York and New Jersey, announced recently that the entire work of construction was nearing completion, and that trains would be running under the river on all lines early next summer.

The tube between Hoboken and Christopher street has been open for several months. The down-town tubes have been completed, save for a small piece of excavation beneath the piers on the New York side, and a small section in the Lackawanna freight yards.

A force of 3,000 men is employed on the work of excavation.

Milwaukee Council Votes for Municipal Light Plant.

The municipal council of Milwaukee, Wis., on October 13, voted to direct the board of public works to build an electric light plant capable of furnishing current for 1,000 arc lamps of 2,000 candle-power each.

Current Electrical News

DOMESTIC AND EXPORT.

NORTHERN CALIFORNIA POWER COMPANY—An issue of $10,000,000 of bonds is contemplated by the Northern California Power Company, Consolidated, to retire the present bonded indebtedness of various subsidiary companies and provide funds for extension. These include the Northern California Power Company, which has a capital stock of $10,000,000. The shareholders meet on November 11 to vote the bonded indebtedness.

NEW POWER COMPANY—The Popo Agie Power, Fuel and Oil Company, capital stock $1,000,000, has filed articles of incorporation and proposes to construct a large power plant near Lander, Wyo., and generate power through the burning of crude oil. This company will be a rival of the Big Horn Power Company, which is building a plant to generate 10,000 electrical horse-power from the flow of the Big Horn River at a point near where the oil-power plant will be located.

CANADIAN PACIFIC RAILWAY ELECTRIC PLANS—Sir Thomas Shaughnessy, president of the Canadian Pacific Railway, says that the company has spent $10,000,000 double-tracking the line between Winnipeg and Thunder Bay in the last year. It will now start on similar work through to the coast, for which $50,000,000 of new stock was voted recently. The company is preparing to operate trains over the mountains for 700 miles by electricity generated by water power.

MEXICAN ELECTRICAL NOTES—The work of installing the underground system of the Telefonos Comerciales of Morelia, Mexico, a corporation made up of local business men, has been completed. The work has been under the direction of the Siemens-Schuckert Werke and cost $40,000. The legislature and the state government of Puebla have conceded a concession to the Cia. Hidro-Electrica de San Agustin, exempting it from all state and municipal taxes for a period of twenty-five years.

WASHINGTON WATER POWER COMPANY LETS CONTRACTS—The Washington Water Power Company, of Spokane, Wash., has awarded a contract to the I. P. Morris Company, of Philadelphia, for the installation of four water-wheels, each weighing 650,000 pounds, and each having a capacity of 9,000 horse-power, with a head of sixty-eight feet. The plant will be located on the Spokane River, fifteen miles west of Spokane, to furnish electric light and power for towns in the vicinity.

MINNESOTA & ONTARIO POWER COMPANY—The Minnesota & Ontario Power Company has been incorporated with a capitalization of $7,000,000. The corporation plans to develop idle water power, establish a paper-manufacturing centre and conduct lumbering operations over a territory of 150,000 square miles. The board of directors is as follows: Edward W. Backus, William E. Brooks, Warren Curtis, John A. Davis, of New York; W. A. S. Peabody, Alexander Smith, of Chicago, and Warren Curtis, Jr., formerly of Corinth, N. Y.

LIGHT COMPANY MORTGAGED—A chattel mortgage for $5,000,000 has been filed at Wapakoneta, Ohio, given by the Indiana Lighting Company, incorporated under the laws of Indiana, to the Central Trust Company, of New York, on all its property in Indiana and Ohio. The mortgage is given to secure a fifty-year four per cent gold bond issue. In addition to all its machinery, pipe lines, gas wells, etc., in various counties, the mortgage covers artificial and natural-gas plants, electric light and power plants in the following cities and towns: Greenville, Ansonia, Lima, Celina, Wapakoneta and St. Mary's, in Ohio, and Ft. Wayne, Lafayette, West Lafayette, Logansport, Peru, Wabash, Frankfort, Lebanon, Bluffton, Montpelier, Geneva and Anderson, in Indiana.

EXTENSIVE SOUTHERN POWER DEVELOPMENT PLANNED —D. G. Zeigler, a consulting engineer and architect, of Atlanta, Ga., has made an inspection of the Suwanee Falls, a few miles above White Springs, Fla., on the Suwanee River, with a view to developing the power at that place. It is said that a large company has purchased the falls and will begin at once the work of development. The falls have a capacity of about 90,000 horse-power in good seasons and a minimum capacity of 30,000 horse-power when the river is high. The concern has a capital of $3,000,000. Blue prints have been made of the territory within seventy-five miles of the falls, extending nearly to Douglas on the north, Thomasville on the west, and taking in Palatka on the south, Jacksonville and Fernandina on the east. It is said that interurban electric lines are to be established between the towns within this circle. One of the lines will go from Valdosta toward Quitman and Boston on the west, to Waycross on the east, thence toward Fernandina and Jacksonville. Another line will go from Valdosta to Jasper and on toward Live Oak, Lake City and other Florida points. Several lines will run out from Jacksonville, Lake City and other large towns in the circle. The territory to be reached in this way embraces over half a million people. It is understood to be the purpose of the company to also furnish power and lights for the various towns. It is said that the power can be developed for about $35 per horse-power per annum.

ELECTRIC LIGHTING.

GUERNSEY, OHIO—Frank C. Smith has applied for a twenty-five-year lighting franchise to light the town of Byesville.

ANDERSON, CAL.—The citizens of Anderson are arranging to have the village electrically lighted by the Northern California Power Company.

CONROE, TEX.—The electric light plant has recently changed hands, F. K. Nance having sold the plant to Lee Ouалline, of Keenan, Tex., who has already taken charge.

CENTRAL CITY, COL.—It is announced that the Hampton Consolidated Mines Company will install a complete electrical plant for the thorough development of the property.

CHATHAM, N. J.—A contract made with the Commonwealth Water and Light Company, of Summit, for a supply of electric current during the daytime has been accepted by the borough council.

CODY, WYO.—The Reclamation Department has decided to install an electric plant at the Corbett dam of the Shoshone reclamation project and to supply electricity at cost to the settlers under the project.

CORONADO, CAL.—The board of trustees has signed a five-year lighting contract with the Coronado Beach Company for fifty sixty-candle-power lamps, the town to pay $87.50 per month for the service.

DELAWARE, OHIO—The Delaware Electric Light and Heating Company has been awarded the contract for lighting the city for the next ten years. The cost of each arc light will be $75 and there are 148 in the city.

BURLINGAME, CAL.—The city council has entered into a contract with the United Gas and Electric Company whereby the company will furnish the municipality with twenty-six arc lights during the coming year for $56.50 each.

BAY CITY, TEX.—A. L. Strong, of New York, has purchased an interest in the electric light and ice plant and will put about $30,000 into the company. The capacity of the ice plant will be increased to forty-five tons daily and a larger generator installed.

WATERLOO, IOWA—The city council at Waverly, where the electric light and water plants were burned recently, has decided to submit to the electors a proposition to issue $30,000 in bonds for the erection of new plants. As the council is limited by law in the expenditure of funds to one and one-fourth per cent of the actual value of the property, a special election must be called to authorize its action.

BURLINGTON, WIS.—The contract for street lighting for five years has been let to the Burlington Electric Light and Power Company. Ten 1,200-candle-power arc lights at $65 each a year and ninety eighty-candle-power incandescents at $27 a year will be used.

ST. LOUIS, MO.—The Glasgow estate is contemplating the construction of a waterworks and electric light plant to supply the 600 acres on the hill to the west of the present city waterworks reservation, and the subdivision of the property for suburban homes.

OSWEGO, N. Y.—Edwin L. Huntington, of Mexico, has sold the electric lighting plant at that place to the Mexico Lighting Company for $15,000. The lighting company has executed a mortgage on its property for $10,000 to Charles A. Peck as trustee.

MINNEAPOLIS, MINN.—The Minneapolis General Electric Company will increase its distributing capacity a fourth in the residence and business districts of Minneapolis. This announcement is made by A. W. Leonard, manager. Additional feeders will be put in.

ATLANTA, GA.—On the application of the Knickerbocker Trust Company, of New York, the Gainesville Electric Railway Company has been placed in the hands of a receiver by Judge Newman, of the United States Court here. Samuel C. Dunlap, of Gainesville, was named receiver and his bond was fixed at $10,000.

SPARTANSBURG, S. C.—F. H. Knox, vice-president and general manager of the Electric Manufacturing and Power Company, which concern owns the power plant at Gaston Shoals, on Broad River, states that the company is figuring on building another power plant either on Broad River or at Nesbitt Shoals, on Tyger River.

HUNTINGTON, L. I.—The Huntington Light and Power Company, the stock of which is held principally by Brooklyn and Manhattan men, wno are summer residents here, has decided to more than double the capacity of the plant at Halesite. This is made necessary by the constantly increasing business of the company.

FARRAGUT, IOWA—A company has been formed by Farragut citizens, with J. J. Whisler at the head, to be known as the Farragut Light and Power Company, and this company will take over the franchise secured by J. A. Masters and J. J. Whisler. The contract provides for forty street lights at a minimum price of $300 per year.

WAYCROSS, GA.—J. E. Wadley, president of the Waycross Electric Light and Power Company, has offered the entire electric light plant, with present contracts, to the city of Waycross for $50,000. If no inclination is shown on the part of the city to purchase the plant, Mr. Wadley will have it enlarged considerably and improved throughout.

LA CROSSE, WIS.—Preliminary steps are being taken in order to determine the advisability of establishing a municipal lighting plant in this city. The plant will cost about $40,000 and will be used to serve only the city buildings and the streets. Application will be made to the state railroad commission to ascertain whether permission will be granted to erect the plant.

DAYTON, OHIO—F. M. Tait, general manager of the Dayton Lighting Company, has closed a deal for the purchase of the Middletown Electric Lighting Company's plant. The purchase price, it is understood, is $100,000. Associated in the deal are Albert Emanuel and L. A. Coppock, of this city. The Middletown plant needs repairs and the company expects to spend about $50,000 for this purpose.

BATAVIA, N. Y.—Judge Hazel, of the United States District Court, at Buffalo, has appointed Marc W. Comstock, a Buffalo lawyer, as receiver for the Genesee County Electric Light, Power and Gas Company. The company has been in business but a few months and distributes Niagara power in Batavia, Oakfield, Akron and Clarence, obtaining its power from the Niagara & Lockport company.

NEWBURGH, N. Y.—The Public Service Commission, Second District, has consented to the lease by the Electric Light Company of New Paltz to the Newburgh Light, Heat and Power Company of the right to use, so far as it may be practicable, for a term of ten years, part of its electric pole system in the village of New Paltz, and to string and erect thereon a high-tension transmission line.

AUGUSTA, GA.—Incorporation of the Georgia Power Company, of Gainesville, is announced. The concern has been formed with a capital stock of $500,000 to develop water-power properties and build electric plants for distribution of power among manufacturing plants and also to promote cotton-mill building in this territory. Jack J. Spaulding, H. G. Pryor and James A. Rudolph are the incorporators.

GRIDLEY, TENN.—The village board of trustees has entered into contract with two citizens, Messrs. Miller and Kirk, for arc lights to illuminate the business section of the town. There are to be sixteen arcs in all. Miller and Kirk agree to supply the sixteen arcs for $83.33 per month. Work on the plant is to be started at once, and it is hoped to have the system in operation by February 1.

BRISTOL, TENN.—Judge S. K. J. Kirkpatrick, J. Frank Toney, W. S. Erwin and W. T. Tucker and others have made application for a charter for the Southern Electric and Power Company, which proposes to do business at Erwin, Unicoi County, using the water power of the Chuckey River. The purpose of the company is to light the town of Erwin by electricity and to eventually furnish power for power purposes.

LUCEDALE, MISS.—At a recent meeting the Lucedale Light and Power Company was organized with the following officers and directors: Dr. W. D. Ratliff, president; C. N. Buffum, vice-president; P. J. Goodman, secretary and treasurer; Dr. W. D. Ratliff, C. N. Buffum, T. A. Banks, G. M. Luce, F. M. Young, Dr. J. A. Dorsett and T. R. James, directors. Work on the installation of an electric light plant has been started.

STOYESTOWN, PA.—Stoyestown and Sprucetown will be lighted this winter by electricity, according to the men at the head of a new light company recently formed and granted a franchise. A plant will be located between the two towns and work on its construction will be started soon. The poles are being planted along the principal streets of the town. The officers of the company are as follows: President, Daniel Long; secretary, Valentine Muller; treasurer, Earl Fulton.

DANVILLE, IND.—The Danville Light, Heat and Power Company has purchased ground along the Big Four Railroad, on the south edge of Danville, and will at once begin the erection of a new and much larger power plant. The building will be of steel, brick and cement and will be 50 by 114 feet. The new plant will furnish a twenty-four-hour service, and in addition to lighting Danville, will also furnish the current for Plainfield and Brownsburg and to farmers along the line.

PINE BLUFF, ARK.—A deed has been filed transferring all of the property of the old Pine Bluff Light and Water Company to the Pine Bluff Corporation. The property was recently publicly sold to satisfy judgment in Federal Court. The purchase price was $450,000. Mortgages signed by the Pine Bluff Corporation to the New York Trust Company for $750,000 were also placed on record. The proceeds of this transaction will be used in rebuilding the gas, water and electric plants to be operated by the company.

SCRANTON, PA.—George N. Tidd, general manager of the Lackawanna Valley Electric Light and Power Supply Company, of this city, which was recently taken over by the American Gas and Electric Company, makes the announcement that the latter concern has made an appropriation of $200,000 to be expended on the local plant. It is proposed to change the service from 1,200 to 2,300 volts. The transformers will be renewed and the plant given a thorough overhauling. A transmission line from Scranton to Carbondale will be erected.

DENVER, COL.—Electrical power for mines and mills in Clear Creek County will be furnished by the Continental Mines, Power and Reduction Company, which has just completed a hydroelectric water and power transmission plant at Yankee. Water power is secured by impounding the waters of River Fall River, Cumberland and Silver creeks. The three streams are united and carried by means of an 8,000-foot flume to a fore-bay and penstock. From the penstock to the power-house there is a fall of 550 feet. George H. Sethman is consulting engineer of the power company.

ELECTRIC RAILWAYS.

BERKELEY, CAL.—The town board has granted the Key Route Company a forty-eight-year electric railway franchise.

BALTIMORE, MD.—R. W. Beall, of the real estate firm of Moore & Hill, is behind a project for the building of another electric line between Baltimore and Washington, D. C.

IOWA CITY, IOWA—Iowa City voters will pass upon the granting of a franchise for the construction and operation of a street-car system in Iowa City at the general election November 3.

SHERMAN, TEX.—Citizens of Sulphur, Okla., have begun active work to build a road from there to Sherman. The line will connect with the electric interurbans running to Oklahoma City, Dallas and Fort Worth.

OMAHA, NEB.—At a meeting of the Independent Transportation Company, of this city, it was decided to abandon the proposition to establish an automobile bus line, and instead to plan for a track railway with gasolene motors or electric cars.

CLEVELAND, OHIO—The Municipal Traction Company has awarded a contract to the Cincinnati Car Company for the changing of fifty old-style cars to pay-as-you-enter cars. Side seats will be replaced by cross seats, with centre aisles.

WACO, TEX.—It is announced that a bonus of $100,000, right of way and franchises in Waco, Temple and Marlin, will be given the parties who will build the interurban connecting these towns. The offer was decided on at a joint conference here.

SYRACUSE, N. Y.—Work has been started on the final survey of the extension of the Rochester, Syracuse & Eastern electric road from Port Byron to this city, and it is expected that building operations on the road will be commenced the first of the year.

TRENTON, N. J.—Chancellor Pitney has continued the receivership of the Camden & Trenton Railway Company, with Wilbur F. Sadler as receiver, until December 29, that the bondholders' committee may confer further, looking toward a reorganization of the company.

BUFFALO, N. Y.—The Pinckerton Construction Company, of Philadelphia, has been awarded a contract for completing an important link of the trolley system of the Buffalo Southern Railway, from the Seneca street city line. The contract covers a six-mile stretch from the city line.

SNOHOMISH, WASH.—Application has been made to the city council for a street-car franchise for the operating of an electric system of railways in the city. The application was made by J. M. Shawhan, formerly chief clerk of the Oregon Railway and Navigation Company, and J. D. Brown.

EDGEFIELD, S. C.—The incorporators of the Augusta & Edgefield Electric Railway have awarded the contract to survey the line to Jones, Requarth & Kelsey, of Charleston. The survey will cover two routes, one from Augusta to Newberry, *via* Edgefield and Saluda; the other from Augusta to this place and to Greenwood.

SPRINGFIELD, ILL.—Officials of the Illinois Traction System announce that the right-of-way for the proposed Saline county line connecting Carrier's Mills with Eldorado and incidentally a step in the direction of the proposed Cairo-East St. Louis line has been secured and that operations on that road will be inaugurated at once. A franchise to operate cars through Eldorado has been granted.

SPIRIT LAKE, IOWA—At a meeting of Spirit Lake aldermen and citizens, presided over by A. B. Funk, it was voted that the Sioux City-Spirit Lake interurban line be granted a franchise on the streets of that city, together with an electric light franchise and the use of a ten-acre tract of land for the location of a power-house and terminals.

HARRISBURG, PA.—Governor Stuart approved an application for the extension of the route of the Cumberland Railway Company, which was granted a charter recently, to operate in Middlesex Township, Cumberland County. The extension covers thirteen miles of Carlisle streets and the various townships in that vicinity. W. E. Glatfelter, of Balfour, is the president.

JEANNETTE, PA.—The contract for grading and building the Jeannette, West Newton & Monongahela Valley Street Railway has been awarded to the A. W. Sperry Company, of Connecticut. Engineers are at work setting the grade stakes and the contractor will follow with a large force of men grading and building the road. The intention at present is to build the road from Jeannette to West Newton and later to the Monongahela Valley.

WASHINGTON, D. C.—The Washington, Alexandria & Falls Church Electric Railway has placed on record a mortgage on all of its property to secure an issue of $1,000,000 in bonds. The Girard Trust Company, of Philadelphia, is trustee under the mortgage, the object of which is to pay off two previous mortgages aggregating $350,000 and to devote the remainder to repairs and purchase of new equipment. The company was recently relieved of receivership.

SAN RAFAEL, CAL.—At a meeting of the board of supervisors Charles Murphy, a San Francisco capitalist, made application for an electric railroad franchise to include practically all the towns of Southern Marin. He plans to run one trolley line from Sausalito to Mill Valley, another from Mill Valley junction across the marshes to Belvedere and Tiburon and a third from Alto station to Corte Madera, Larkspur, Kentfield, Ross, San Anselmo and San Rafael.

PITTSBURG, PA.—A new traction system is proposed here to connect with the Pittsburg Railways Company and traverse portions of the suburbs. The Carnegie & Castle Shannon Railway Company, Banksville & West End Traction Company and the Liberty & West Liberty Traction Company are being formed to develop sections south of the Ohio and Monongahela rivers. They have applied for permission to construct lines on the new country roads to the several towns indicated in the names of the companies.

DOYLESTOWN, PA.—It is said that the Philadelphia Rapid Transit Company has acquired control of the Philadelphia & Easton Electric Company, which runs a trolley line, thirty-six miles long, from here to Easton, which cost more than a million dollars to build. This will give a continuous line from Philadelphia to Easton under one management. It is also reported that the company operating the trolley line from here to Bristol will furnish a certain amount of money to build the Doylestown-Perkasie trolley, provided a certain sum is subscribed by those interested along the line.

TAYLORVILLE, ILL.—A contract has been let by the Taylorville Light and Heat Company for the construction of the street railway track and overhead equipment to the Chicago Installation Company for $61,800. The track is to be four miles and 100 feet long and will extend from the extreme northeast end to the extreme southeast part of Taylorville. The company also purchased forty acres of land from L. D. Hewitt at the southwest terminus of the track for the purpose of laying out a city park. The power-house is now under course of construction. The company is capitalized at $150,000.

MOLINE, ILL.—Engineer W. H. Kimball has made his report to the stockholders of the proposed Davenport and Manchester interurban road of the result of the preliminary survey. The report shows that the Manchester line will be 94.9 miles, exclusive of sidetracks and one or two branches that were merely investigated. The cost will be $1,242,610, exclusive of railroad crossings, sidetracks and depots. The cost of fencing in the right of way will be $30,800 additional. George T. Baker, who has been president, has resigned and the road is at present under the direction of J. A. Voorhees, vice-president. F. W. Rank, of this city, is secretary.

COOPERSTOWN, N. Y.—The Oneonta & Mohawk Valley Railroad, an electric line connecting Herkimer and Oneonta, has been sold by auction to Joseph A. Starrett, New York. The sale was made under mortgage foreclosure brought by the Knickerbocker Trust Company, of New York. Mr. Starrett was the only person present who qualified to bid, and his first offer of $200,000, the minimum figure set by the order of the court, was accepted by the referee. The sale was made subject to receivers' certificates and other obligations amounting to over $300,000. It is reported on good authority that the purchase was made for Herbert T. Jennings, who as promoter constructed the road.

PERSONAL MENTION.

MR. CLEMENT C. SMITH, of Milwaukee, Wis., has been elected president of the Wisconsin Electric Company to succeed O. C. Fuller.

MR. BERTRAM M. DOWNS has been elected vice-president of the Brookfield Glass Company, with headquarters in the United States Express Building, New York city.

MR. F. V. L. SMITH, who has been in charge of the Sprague Electric Company's office in New Orleans, La., since its establishment, has opened a branch office for the company in Atlanta, Ga. Mr. Smith will be in charge of both offices.

MR. J. M. BAKER, for several years district manager for the New England Telephone and Telegraph Company at Lynn, Mass., has been promoted to the office of district plant chief, with headquarters at Salem. Fred A. Phillips has been placed in charge of the Lynn office.

MR. MATTHEW A. SAMMETT has severed his connection with the Montreal Light, Heat and Power Company as engineer in charge of tests and design, and will hereafter devote his entire time to consulting engineering work, with headquarters in the Canadian Express Building, Montreal, Canada. Mr. Sammett has had a wide experience in the electrical field, having been connected for a long time with the General Electric Company and a number of other companies.

LORD NORTHCLIFFE (Alfred Harmsworth), the celebrated English publisher, and Lady Northcliffe spent some time last week inspecting the power developments at Niagara Falls. On the morning of October 21 Lord and Lady Northcliffe visited the plant of the Ontario Power Company, on the Canadian side. After inspecting the plant Lord Northcliffe declared that the transmission of electric power to such great distances was a wonderful thing, and expressed his belief that in time that section of the country would be one of the greatest manufacturing centres of the world. Lord Northcliffe had not visited Niagara Falls in fifteen years and was greatly impressed with the growth of the city since his earlier observation.

OBITUARY NOTE.

COLONEL W. W. RIDER, of Allentown, Pa., during the past two years traffic manager of the Consolidated Telephone Companies of Pennsylvania, died on October 24 from typhoid fever at St. Luke's Hospital, South Bethlehem, Pa., aged fifty-eight years. He was connected with the telephone business many years.

NEW INCORPORATIONS.

YONKERS, N. Y.—Westchester County Automatic Telephone Company. $100,000.

HARRISBURG, PA.—Macungie Electric Light, Heat and Power Company, of Macungie. $5,000.

DENVER, COL.—Telluride Power Company. Capital increased from $2,500,000 to $10,000,000.

BOSTON, MASS.—Rock Hill Telephone Company, Boston. To carry on a telephone and telegraph business. $50,000. President, S. R. Smith; treasurer, P. Workman, Rock Hill, S. C.

ALBANY, N. Y.—Summit Telephone Company, of Schoharie County. $2,500. Directors: George Skidmore, Eli Baker, Alvin Joslin, C. F. Wharton, Frank Cox, of Summit, and Myron Grey, of Fulton.

LITTLE ROCK, ARK.—Eldorado Telephone Company. $50,000, all of which is subscribed. Incorporators: P. C. Blain, president; W. P. Ritchie, B. Arrett, T. F. Gaughan, B. C. Powell and H. S. Powell.

RICHMOND, VA.—Craig Water Power Company, Roanoke. To generate power for use in Roanoke. $5,000 to $200,000. A. L. Sibert, president; L. A. Scholz, vice-president; Henry Scholz, secretary and treasurer, all of Roanoke, Va.

ALBANY, N. Y.—Dwaas Electric Company. $20,000. Directors: Edward E. Sabourin, Sandy Hill; George Gifford, Schenectady; Harold J. Werner, Mechanicsville; Adam Rathgeber, New York city; Andrew T. G. Wemple, Schenectady, and Alfred Stoodley, Schenectady.

ELECTRICAL SECURITIES.

The market last week, while not displaying any very pronounced upward tendency, gave unmistakable evidence of the soundness of underlying conditions. The presidential election is still an important factor in the situation, but from the present indications it would appear that a considerable betterment in business generally is to be hoped for. The iron and steel trade shows some improvement, although, as elsewhere, a hesitating pre-election tone tends to curtail betterment.

Dividends have been declared upon the following electrical securities: Electrical Securities Company; semi-annual dividend of 2½ per cent, payable November 2. Montreal Street Railway Company; quarterly dividend of 2½ per cent, payable November 2. Butte Electric and Power Company; quarterly dividend of 1¼ per cent, payable November 2. American District Telegraph Company of New York; regular quarterly dividend of 1 per cent, payable November 15 to stock of record November 1. Ohio Traction Company; regular quarterly dividend of 1¼ per cent on the preferred stock, payable November 2. Montreal Light, Heat and Power Company; regular quarterly dividend of 1½ per cent, payable November 16.

ELECTRICAL SECURITIES FOR THE WEEK ENDED OCTOBER 24.

New York:	*Closing.*
Allis-Chalmers common	11¼
Allis-Chalmers preferred	35½
Brooklyn Rapid Transit	49¼
Consolidated Gas	144
General Electric	140
Interborough-Metropolitan common	10
Interborough-Metropolitan preferred	29⅛
Kings County Electric	125
Mackay Companies (Postal Telegraph and Cables) common	79½
Mackay Companies (Postal Telegraph and Cables) preferred	69
Manhattan Elevated	136
Metropolitan Street Railway	24
New York & New Jersey Telephone	114
Western Union	60¼
Westinghouse Manufacturing Company	81

At a meeting of the board of directors of the Western Union Telegraph Company all of the present officers and members of the executive committee were re-elected.

Boston:	*Closing.*
American Telephone and Telegraph	127
Edison Electric Illuminating	230
Massachusetts Electric	50
New England Telephone	120
Western Telephone and Telegraph preferred	70

Philadelphia:	*Closing.*
Electric Company of America	9¾
Electric Storage Battery common	36
Electric Storage Battery preferred	36
Philadelphia Electric	11
Philadelphia Rapid Transit	22⅝
United Gas Improvement	87¼

Chicago:	*Closing.*
Chicago Telephone	124
Commonwealth Edison	108¼
Metropolitan Elevated preferred	—
National Carbon common	68
National Carbon preferred	110

DATES AHEAD.

American Electrochemical Society. Fall meeting, New York city, October 30-31.

Association of Car-Lighting Engineers. First annual meeting, Chicago, Ill., November 18.

National Society for the Promotion of Industrial Education. Annual meeting, Atlanta, Ga., November 19-21.

International Independent Telephone Association. Annual convention, Chicago, Ill., December 1-3.

American Society of Mechanical Engineers. Annual meeting, New York city, December 1-4.

American Roentgen Ray Society. Annual meeting, New York city, December 28-30.

Chicago Electrical Show. Coliseum, Chicago, Ill., January 16-30, 1909.

American Association for the Advancement of Science. Annual meeting, Baltimore, Md., January, 1909.

Northwestern Electrical Association. Annual meeting, Milwaukee, Wis., January, 1909.

TELEPHONE AND TELEGRAPH.

HAMILTON, ONTARIO—The city council has granted a new franchise to the Bell Telephone Company.

WICHITA, KAN.—A new $12,000 multiple switchboard is being installed in the offices of the Independent Telephone Company.

MINNEAPOLIS, MINN.—The Rolling Stone Telephone Company will conduct a rural telephone system in the vicinity of Rolling Stone with a capital stock of $10,000.

INDIANAPOLIS, IND.—An underground telephone system is to be placed at Fort Benjamin Harrison which will cost between $12,000 and $15,000. Work has been commenced.

CHARLESTON, W. VA.—The Charleston Home Telephone Company will install during the next year 50,000 feet of new cable, which will accommodate 1,000 additional subscribers.

GAFFNEY, S. C.—A corps of telephone men is at work building a telephone line from Gaffney to Pacolet, a distance of about eighteen miles. About twenty telephones will be installed along the route.

DUBUQUE, IOWA—At a meeting of the directors of the Interstate Telephone Company and the local Bell company, held in Dyersville, a contract for toll connections between the two companies was signed.

SAN BERNARDINO, CAL.—The city councilmen have notified the Home Telephone Company that work on the underground system must be commenced within sixty days and completed within six months from date.

LEESVILLE, TEX.—Business men of Leesville and farmers on the route are building a rural route telephone from this place to Union, Wilson County, connecting with the one running through that county; also from there to Nixon and Dewville.

LA CROSSE, WIS.—The Wisconsin (Bell) Telephone Company has absorbed the Western Wisconsin Telephone Company, which has 1,500 subscribers and exchanges in Galesville, Arcadia, Trempealeau, Fountain City, Blair, Ettrick, Whitehall and Independence.

ELDORA, IOWA—The contract for the erection of a building for the Eldora telephone exchange has been let to F. X. White, of Eldora, whose bid was $4,760. The erection of the building is to be begun immediately, and it is to be ready for occupancy by January 1.

SIOUX FALLS, S. D.—Under an order from Judge Carland, of the United States Court, the property of the Citizens' Telephone Company, of Sioux Falls, has been sold to the New State Telephone Company, of Iowa. The purchasers say the local system will be maintained as an independent company. The New State company bid in the property at $94,700. The bidding started at $50,000.

MAHANOY CITY, PA.—In order to improve its telephone system throughout the lower western sections of Schuylkill County, the officials of the American Union Telephone Company are building new lines. During the ensuing two months there will be about seventy-five miles of additional wire strung. The first extension consists of a line from the central station at Pottsville to a point in Mount Carbon.

SHELBURNE FALLS, MASS.—At the annual meeting of the stockholders of the Heath Telephone Company it was voted to authorize the directors to execute a lease of the lines and property of the Deerfield Valley company, a sublicensee of the New England company, and arrange with the latter for long-distance connections, provided satisfactory terms can be made. The following directors were elected: W. E. Kinsman, F. L. Totman, A. J. Patterson, F. H. Smith, W. A. Barber, C. S. Goodwin and H. Newell.

TROY, N. Y.—At a meeting of the stockholders of the Buskirks & South Cambridge Telephone Company Amos Broughton was elected chairman and George Cornell secretary. The report of the treasurer showed a balance on hand of $235. The following directors were elected for the ensuing year: Edward Whiteside, Edgar B. Chase, G. Grant Rich, Charles King, Fred M. Dewey, Ira S. Durfee, Edwin T. Cornell, S. S. Sisson and Harmon Beadle. At a meeting of the directors Edward Whiteside was chosen president, Edgar B. Chase vice-president, Ira S. Durfee secretary and Fred M. Dewey treasurer.

INDUSTRIAL ITEMS.

THE LOMBARD GOVERNOR COMPANY, Ashland, Mass., in bulletin No. 110, gives brief descriptions of those types of Lombard governors which are most frequently used. In addition to the descriptive matter there is incorporated a series of letters concerning the satisfaction many prominent power-users have had in adopting these governors.

THE JEFFREY MANUFACTURING COMPANY, Columbus, Ohio, is distributing some attractive literature devoted to Jeffrey "Century" rubber-belt conveyers, conveying machinery for sawmills, lumber mills and wood-working plants, coal tipples and shaking screens (bulletin No. 22), and coal-washing plants and equipment (bulletin No. 27).

THE SPRAGUE ELECTRIC COMPANY, New York city, is distributing circulars Nos. 432 and 433, the former describing a new line of fittings for use with its flexible steel conduit, and the latter describing the new single-strip type of flexible steel conduit, designed especially for fireproof buildings. Copies of these circulars will be sent upon request.

THE GENERAL ELECTRIC COMPANY, Schenectady, N. Y., in circular No. 3702, describes its new Type CR feeder regulator and the benefits to be derived from the use of such apparatus in connection with alternating-current lighting systems. This regulator is designed for operation on single-phase, 220-volt, sixty-cycle circuit, and may be used with either hand or sprocket control.

THE PHILIPS METALLIC GLOW LAMP WORKS, LIMITED, Eindhoven, Holland, has published a very interesting bulletin describing the Philips metallic glow lamp. The filaments in these lamps are composed of fine pure metal, and the lamp is stated to have a life of 1,000 hours. The lamps are made suitable for burning in any position, and a special form of packing insures against breakage.

MURALT & COMPANY, New York city, have secured the contract for the enlargement and improvement of the hydroelectric plant of the Riverhead Electric Company, of Riverhead. Long Island. The old water-wheels now in use will be taken out and new Trump turbines of the vertical-shaft type will be installed. The electrical equipment will be of the three-phase, alternating-current type, with a frequency of sixty cycles, operating at 11,000 volts. There is also an auxiliary steam plant for emergency purposes.

THE KELLOGG SWITCHBOARD AND SUPPLY COMPANY, Chicago, Ill., has issued a folder describing and illustrating its new push-button intercommunicating telephone system. Five views showing wall and desk-set styles, both open and closed, are given. The accessibility and rigidity of these sets are clearly shown in the illustrations of the open views. Both wall and desk sets are finished in either oak or mahogany, and are made up very attractively. Copies of this folder will be sent to any one interested upon request.

THE WARD LEONARD ELECTRIC COMPANY, of Bronxville, N. Y., announces that its catalogue A3 and catalogue A4, covering Ward Leonard navy-type motor-starting panels, fulfilling specifications of the Bureaus of Construction and Repair, Equipment and Steam Engineering, Nos. 2 M1. 1906, should not be used in quoting upon the latest specifications dated 1907 and 1908 of the Navy. Enclosing cases for panels are specified in these latest specifications, and several minor changes. Until the company's new bulletin is issued, customers should write for special quotations.

THE CINCINNATI MILLING MACHINE COMPANY, Cincinnati, Ohio, is distributing a catalogue devoted to high-power millers. This catalogue illustrates an entirely new line of horizontal and vertical milling machines. The machines are built on the unit system, each group of mechanisms being assembled as a complete unit. All the units are interchangeable between the horizontal and vertical machines. This makes it possible to supply these machines not only with constant-speed drive, but with right-angle drive, constant-speed motor drive and variable-speed motor drive. A change from one style of drive to another is easily made.

THE STANDARD GAUGE MANUFACTURING COMPANY, which has been actively engaged in the manufacture of indicating and recording gauges at Syracuse, N. Y., will move its plant and main office to its new factory at Foxboro, Mass., on or about November 1. Through this change the manufacturing capacity will be greatly increased, since the two main buildings alone have available floor space of one hundred thousand square feet, besides separate buildings for the foundry, blacksmith shop, carpenter shop and power plant. The growth of the Standard Gauge Manufacturing Company has been steady since its inception in 1899, so that this epoch in its development will not surprise its many patrons. The sales offices addresses will be as heretofore: New York, 1770 Hudson Terminal, Fulton Building, and Chicago, 725 Monadnock Building.

Record of Electrical Patents.

Week of October 20.

901,322. ELECTRICAL ACCUMULATOR. Charles Busch, New York, N. Y. Filed July 15, 1908. The active surface is held by burs on adjacent perforated electrodes, and an elastic binder holds the electrodes together.

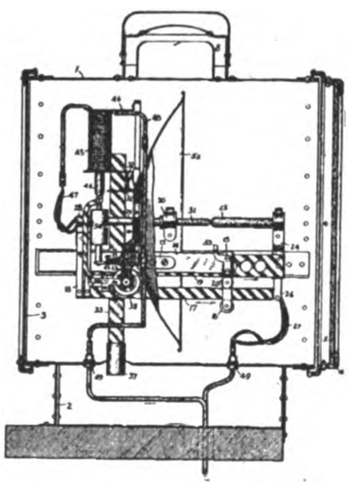
901,331. ELECTRIC RAILWAY SIGNAL. Edward A. Everett, Detroit, Mich. Filed June 27, 1906. The circuit is closed by means of a liquid conductor, and means are provided to open the contact should the fluid conductor fail.

901,332. INSULATING MATERIAL. Willis E. Everette, Tacoma, Wash. Filed May 17, 1906. The material is formed of insoluble fireproof threads composed of calcium, aluminum, silicon and oxygen.

901,336. AUTOMATIC ELECTRIC LIGHTING SYSTEM. Carl J. Gardeen, Columbus township, Anoka County, Minn. Filed December 5, 1907. The system includes a storage battery, a battery for an ignition system, a generator which may act as a motor by reversing the polarity of the armature, and circuit-closing and regulating switches.

901,341. ALTERNATING ELECTRIC-CURRENT MACHINERY. Alexander Heyland, Brussels, Belgium. Filed May 2, 1903. A commutator is provided for simultaneously commutating and decomposing a portion of the current.

901,368. APPARATUS FOR MAGNETIC SEPARATION. Clarence Q. Payne, Stamford, Ct., assignor to the International Separator Company. Filed October 3, 1903. The rotating cylinder is composed of alternately disposed magnetizable laminæ, and revolves in a magnetic field.



901,432.—Arc Lamp Headlight.

901,372. TELEGRAPHY. Louis M. Potts, Baltimore, Md., assignor to the Rowland Telegraphic Company, Baltimore, Md. Filed March 9, 1907. The constants in one circuit are balanced until the constants in a plurality of circuits are brought into equilibrium.

901,377—901,378—901,379—901,380—901,381—901,382—901,383. ELECTRIC RAILWAY SYSTEM. William Robinson, Brooklyn, N. Y. A series of patents embracing broad claims for an electric railway system, employing both direct and alternating currents, signal and relay systems, and means for insulating against the propulsion current sections of the track other than that occupied by the train in motion.

901,393. DEVICE FOR TESTING CANS. Charles W. Sleeper, Lancaster, N. H. Filed April 25, 1908. An incandescent lamp is placed in the bottom of the receptacle.

901,397. APPARATUS FOR RECORDING AND REPRODUCING BY THE TELEGRAPHONE PRINCIPLE. Harve R. Stuart, Wheeling, W. Va. Filed March 2, 1908. The telephone diaphragm imparts movement to a vibratory shaft which energizes reciprocal electromagnets.

901,422. CONNECTOR FOR ELECTRICAL CONDUCTORS. Frank B. Cook, Chicago, Ill. Filed April 2, 1908. The external surface of a tapered one-piece sleeve is threaded to engage with nuts gripping the strands over a wedge piece.

901,423. SWITCH FOR CHARGING AND DISCHARGING STORAGE BATTERIES. James H. Cormick, Belleville, N. J., assignor to the Union Switch and Signal Company, Swissvale, Pa. Filed February 29, 1908. Means are provided upon one panel for effecting different connections.

901,424. ELECTRICALLY CONTROLLED SWITCH. Archibald S. Cubitt, Schenectady, N. Y., assignor to General Electric Company. Filed April 22, 1908. Means are provided for varying the permeability of the current-carrying coil.

901,427. VAPOR ELECTRIC APPARATUS. Leonard E. Dempster, Schenectady, N. Y., assignor to General Electric Company. Filed October 31, 1904. The conductor is embedded in a radiating sleeve consisting of a vitreous material.

901,432. ARC LAMP HEADLIGHT. Richard Fleming, Lynn, Mass., assignor to General Electric Company. Filed June 16, 1905. The electrodes and arc-lamp carriage are supported on horizontally disposed rack rods.

901,440. DYNAMOELECTRIC MACHINE. Arthur L. Hadley, Fort Wayne, Ind., assignor to General Electric Company. Filed May 14, 1906. The field pole has a central section of laminæ interposed between two side sections.

901,441. SELECTIVE SIGNALING SYSTEM. Orlando W. Hart, Fall River, Mass. Filed August 10, 1907. A transmitting device is provided with means to cause a signal to become set.

901,445. PRIMARY BATTERY. Karl Heintz, Munich, Germany, Filed December 26, 1907. A galvanic cell of the Bunsen type with a sulphuric-acid solution and a nitric-acid solution separated by means of a carbon diaphragm.

901,448. FUSE HOLDER. Bryson D. Horton, Detroit, Mich., assignor to Horton-Massnick Company, Detroit, Mich. Filed August 29, 1904. A spring making indication on the exterior of the fuse is attached to the fusible material.

901,477. ELECTRIC RAILWAY SYSTEM. William Robinson, Brooklyn, N. Y. Original application filed July 20, 1904. The working conductor is formed in independent sections, and the power-current feeder is normally disconnected therefrom.

901,479. ELECTRIC PROTECTIVE APPARATUS. Charles A. Rolfe, Adrian, Mich., assignor, by mesne assignments, to Rolfe Electric Company, Rochester, N. Y. Filed April 20, 1903. A non-conducting softenable material is placed in combination with circuit-controlling, spring-actuated devices.

901,497. CARBON ELECTRODE. Joseph T. Szek, London, England. Filed September 23, 1907. The electrode is provided with longitudinal grooves throughout its length and a transverse groove at its base.

901,498. CONDENSER. Elihu Thomson, Swampscott, Mass., assignor to General Electric Company. Filed May 5, 1904. The dielectric sections are graded.

901,499. COMBINED MOTOR AND COMPRESSOR. Charles P. Tolman, New York, N. Y., assignor, by mesne assignments, to the Roteng Manufacturing Company. Filed November 16, 1905. The motor and compressor are mounted on a mechanically continuous shaft.

901,506. VAPOR ELECTRIC APPARATUS. Willis R. Whitney, Schenectady, N. Y., assignor to General Electric Company. Filed October 31, 1904. A metal tube forming one electrode is sealed about the other electrode.

901,509. SWITCH FOR CHARGING AND DISCHARGING STORAGE BATTERIES. Asbury G. Wilson, Wilkinsburg, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Filed February 28, 1908. Two pairs of discharging knives in combination with two pairs of clip contacts pivotally supported.

901,512. RHEOSTAT. Paul H. Zimmer, Schenectady, N. Y., assignor to General Electric Company. Filed May 20, 1907. The controlling arm is spring-pressed toward its initial position, and a circuit-controlling element is independently spring-pressed and arranged to hold the spring pressure from the said arm.

901,513. INDUCTION-MOTOR CONTROL. Ernst F. W. Alexanderson, Schenectady, N. Y., assignor to General Electric Company. Filed July 12, 1906. Means are provided for connecting the primary windings of two polyphase induction motors in parallel with one phase connected to the source, and means for connecting either motor mechanically to the load.

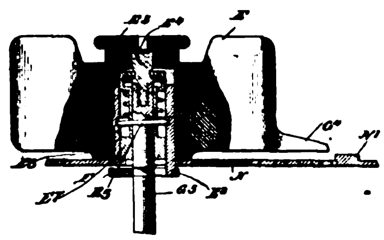
901,514. SYSTEM OF MOTOR CONTROL. Hans Alexander, Berlin, Germany, assignor to General Electric Company. Filed May 20, 1907. Means are provided for controlling the field strength of the generator to vary the voltage supplied to the motor.

901,529. ARC LAMP. Richard Fleming and Cromwell A. B. Halvorson, Jr., Lynn, Mass., assignors to General Electric Company. Filed May 16, 1904. The electrodes are given a somewhat violent engagement at intervals in the operation of the lamp.

901,540. COMBINED ELECTRIC ALARM AND LIGHT. William A. Lindsey, Narberth, Pa. Filed July 18, 1907. A relay-controlled lamp system is interpolated in the alarm circuit.

901,570. TELEPHONIC TRANSMITTER. Frederick G. Warrell, Lansdowne, Pa., assignor to the Euelectric Company. Filed October 3, 1907. The loose material occupies all the space between the vibrating diaphragms.

901,593. OUTLET BOX. Harry A. Coffin, Malden, Mass. Filed January 12, 1907. Means are provided for limiting the vertical movement of the bushing and covering plate.



901,630.—Operating Means for Circuit-Controlling Devices.

901,613. ELECTROMECHANICAL REGULATOR FOR ELECTRIC TENSION. Joseph M. C. Herrgott, Valdole, France. Filed April 27, 1906. The solenoid-operated plunger is assisted by the action of pneumatically or fluid-controlled valves.

901,614. CIRCUIT-BREAKER. Edward M. Hewlett and Theodore E. Button, Schenectady, N. Y., assignors to General Electric Company. Filed October 22, 1904. The circuit-breaker is provided with a scale and means for indicating the adjustment of the armature on the scale.

901,627. INSULATOR. Royal T. Langlan, Boston, Mass. Filed December 10, 1907. The two separable sections have abutting faces, one section constituting a spacer and the other being formed to enclose the lower end of a bolt.

901,630. OPERATING MEANS FOR CIRCUIT-CONTROLLING DEVICES. Julius K. Lux, Washington, D. C. Filed July 31, 1906. Means are provided to allow the indicator to rotate independently of the switch when power in excess of a predetermined amount is applied thereto.

901,649. SPACE TELEGRAPHY. Oscar C. Roos, Newton, Mass., assignor to Stone Telegraph and Telephone Company, Boston, Mass. Filed June 10, 1907. An elevated conductor has a parallel branch circuit connected in series therewith, containing capacity and inductance in each of its branches.

901,668. SAFETY APPARATUS FOR RAILWAYS. Samuel L. Adelson, New York, N. Y., assignor of one-half to Maurice Adelson, New York, N. Y. Filed March 18, 1908. The track apparatus is arranged in blocks, and the alarm is carried in the car.

901,669. MULTIPARTY-LINE TELEPHONE-EXCHANGE SYSTEM. Garrison Babcock, Rochester, N. Y., assignor to Stromberg-Carlson Telephone Manufacturing Company, Rochester, N. Y. Filed August 4, 1904. A normally open passing contact switch at the substation is adapted to momentarily close the circuit upon depression of an associated receiver hook.

901,672. MULTIPLE-SWITCHBOARD JACK. Jules A. Birsfield, Rochester, N. Y., assignor to Stromberg-Carlson Telephone Manufacturing Company, Rochester, N. Y. Filed February 13, 1905. The bending of the switch spring affects the bending area of the supporting shelf.

901,683. SUPERVISORY SYSTEM. Merritt S. Conner, Chicago, Ill., assignor to Stromberg-Carlson Telephone Manufacturing Company, Rochester, N. Y. Filed March 5, 1904. In a supervisory signal an armature is provided, absolutely controlling a circuit through the said signal.

901,684—901,685—901,686—901,687—901,688—901,689. TELEPHONE-EXCHANGE SYSTEM. Merritt S. Conner, Rochester, N. Y., assignor to Stromberg-Carlson Telephone Manufacturing Company, Rochester, N. Y. A series of patents covering various features of a telephone-exchange system.

901,696. TELEPHONE-EXCHANGE SYSTEM. William M. Davis, Chicago, Ill., assignor, by mesne assignments, to Stromberg-Carlson Telephone Manufacturing Company, Rochester, N. Y. Filed April 26, 1901. A combination with a telephone switch hook at subscriber's station for opening and closing the telephone circuit thereat.

901,698. AUTOMATIC TELEPHONE-EXCHANGE SYSTEM. Bert G. Dunham, Chicago, Ill., assignor to Stromberg-Carlson Telephone Manufacturing Company, Rochester, N. Y. Filed October 5, 1904. An automatic telephone system.

901,704. RECEIVER. John S. Goldberg, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company, Rochester, N. Y. Filed November 23, 1903. The casing consists of a continuous one-piece shell of magnetic material, of which diametrically opposite regions are oppositely polarized.

901,738. SUBSCRIBER'S TELEPHONE CIRCUIT. Howard M. Post, Chicago, Ill., assignor to Kellogg Switchboard and Supply Company, Chicago, Ill. Filed July 31, 1905. The path for the signaling circuit contains the coils of a suitable ringer.

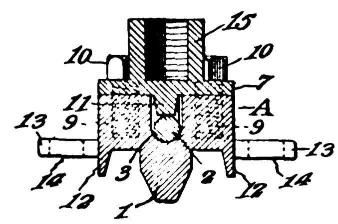
901,758. ELECTROLYTE. Abraham Van Winkle, Newark, N. J., assignor to the Hanson & Van Winkle Company, Newark, N. J. Filed October 24, 1907. The electrolyte comprises fluoride of zinc in solution.

901,765. MAGNETIC SEPARATOR. Reuben I. Wright and Homer E. Frost, Cleveland, Ohio, assignors to the Electric Controller and Supply Company, Cleveland, Ohio. Filed May 10, 1907. Mechanical connections with the valve-operating mechanism close the switch contacts prior to the opening of a hopper valve.

901,785. TELEPHONE SYSTEM. Elmer R. Corwin, Chicago, Ill., assignor to Corwin Telephone Manufacturing Company, Chicago, Ill. Filed December 26, 1906. A multiple selectively controlled telephone-exchange system.

901,816. TROLLEY-WIRE ANCHOR. Allan McIsaac, Hartford, Ct. Filed March 4, 1908. A horizontal plate-like bridge-piece has a tongue extending into a reciprocal groove for gripping the wire.

901,847. ELECTRIC MAIL-DELIVERING AND COLLECTING MACHINE. Otto E. Stout, Ozark, Ill. Filed June 30, 1908. The combination of a trackway and a motor-driven movable carrier.



901,816.—Trolley-Wire Anchor.

901,850. TELEPHONE-RECEIVER HOLDER. George J. Thomas, New York, N. Y. Filed August 14, 1907. An arm is pivotally mounted upon the bifurcated portion of a telephone-receiver holder.

901,861. TELEGRAPHIC SOUNDER. Vincent C. de Ybarrondo, Los Angeles, Cal. Filed May 6, 1907. An attachment comprising a U-shaped metallic member in combination with a hammer.

901,869. PROTECTOR FOR TELEPHONE TRANSMITTERS. Josef Baumgarten, New York, N. Y. Filed January 18, 1908. The mouthpiece is furnished with a collapsible funnel of flexible material.

901,871. ELECTRIC HEATER AND DRIER. George N. Blanchard, San Francisco, Cal., assignor of one-half to the Electric Manufacturing Company, San Francisco, Cal. Filed February 21, 1908. The air is discharged through a pyramidal electric resistance fixed within a tube.

901,878. TROLLEY-WHEEL BEARING. William M. Caswell and Joseph A. Schofield, Warren, Pa. Filed December 16, 1907. The bearing comprises fixed and hinged sections.

901,885. ELECTRIC CONTACT SPRING FOR TROLLEY HARPS. Albert L. Cole, Auburndale, Mass., assignor to United Copper Foundry Company, Boston, Mass. Filed September 28, 1905. A normally compressed washer portion is expansible both radially and transversely.

901,894. INDICATOR FOR TELEPHONE CALLS. Eugene T. Ducharme, Boston, Mass. Filed November 15, 1907. An indicator disc is carried upon the clapper arm.

901,899. ELECTRIC SIGNALING SYSTEM FOR RAILWAYS. William J. Higgins and Christopher J. Sheridan, Buffalo, N. Y. Filed December 27, 1907. A motor actuates the danger-signal semaphore arm in combination with secondary coils mounted upon the car.

ELECTRICAL REVIEW
AND
WESTERN ELECTRICIAN

VOL. LIII. No. 19. CHICAGO, SATURDAY, NOVEMBER 7, 1908. ISSUED WEEKLY

BY THE
ELECTRICAL REVIEW PUBLISHING COMPANY.
CHARLES W. PRICE, President.
STEPHEN H. GODDARD, Vice-President. H. S. TUTHILL, Secretary.
C. W. FORBRICH, Assistant Treasurer.

PUBLICATION OFFICE: 204 DEARBORN STREET, CHICAGO.

The present publication comprises: ELECTRICAL REVIEW, VOL. LIII, No. 19; WESTERN ELECTRICIAN, VOL. XLIII, No. 19.

EASTERN DEPARTMENT . . . . 13 Park Row, New York.
Philip S. Dodd and E. E. Wood.
WESTERN DEPARTMENT . . . . 204 Dearborn Street, Chicago.
Frank L. Perry.
EUROPEAN OFFICE . . . . 42 Old Broad Street, London, E. C.
Henry W. Hall.

CONTENTS.

PUBLISHER'S ANNOUNCEMENT.

With the present issue the ELECTRICAL REVIEW, of New York, and the WESTERN ELECTRICIAN, of Chicago, join forces, and make their bow as the "ELECTRICAL REVIEW AND WESTERN ELECTRICIAN." The success with which both these journals have been conducted in the past is an assurance that the combination of forces will create a great national electrical weekly of influence and value to readers and advertisers alike. The ELECTRICAL REVIEW is the product of twenty-seven years' service in the development of all that is best in the electrical industry. The WESTERN ELECTRICIAN was founded in Chicago twenty-two years ago, maintaining a prominent position as a thoroughly representative journal, receiving the support of the entire western electrical fraternity.

In consolidating these two publications the editorial and business organizations of both have been continued and merged, and the western and eastern offices have the support of strong editorial and business departments. Those characteristics which have made each journal distinctive, and which have been rewarded with loyal support, will be preserved, and a constant effort made to improve the ELECTRICAL REVIEW AND WESTERN ELECTRICIAN along every line which good judgment and the necessity of the electrical reading public may dictate. This journal will continue to be of interest and value to the technical man with its contributions and editorials concerning highly specialized fields of research and operation; and along those lines which interest the practical man and indicate the best methods of conducting public service utilities of the smaller size, the paper will be strengthened in every direction.

THE ELECTION.

On November 3 the voting citizens of the United States cast their ballots and elected to office for the conduct of the national administration the candidates of the Republican party. So considerable was the majority that it would appear that the question, shall the people rule, has been definitely settled nationally for the next four years at least. The policies of the present administration have been endorsed, and the attitude of all good citizens should now be to support the incoming administration without respect to partisanship. The constant betterment in industrial circles which has been going on for the past three or four months has been an indication of the growing confidence of investors in general in the stability of the institutions in which their fortunes were involved. It remains now for a healthy continuation and stimulation of this confidence to bring about a new era of prosperity, and a golden opportunity for all men to make the best of life and liberty and the pursuit of happiness.

Statewise it appears that in those commonwealths where public service commissions have been inaugurated through legislative action, and where a change in administration might have jeopardized the continuation of these commissions, that the will of the people has spoken for their continuance. Already there has been a concession of admiration on the part of public utility corporations for the sanity and benevolence of properly governed and practically restricted regulating commissions, the companies realizing that no commission can effect the confiscation of a real investment so long as the courts are open to the public and the public service corporation alike. The old bugaboo of municipal ownership seems not to have been raised at all in the recent campaign, and it can be stated with little prospect of controversion that municipal ownership has died a peaceful death, and that its demise has been due to the turning on of the light of intelligent publicity by the public service corporations in the largest cities in the country, particularly those where public service commissions have been instituted.

In Illinois the International Improvement Commission issued a circular asking votes in favor of a proposed $20,000,000 bond issue to be used in constructing a waterway from Lockport to Utica, Ill. This will provide an important link in the deep waterway from the lakes to the gulf. The matter came up before the voters as an amendment to the constitution permitting the bond issue. The present drainage canal extends twenty-nine miles from the south branch of the Chicago River, in Chicago, to the city of Lockport, where it connects with the Desplaines River. There is a further extension of one and three-quarters miles to the powerhouse between Lockport and Joliet, where there are at present three 4,000-kilowatt generators, a fourth being in process of erection, and where four more are to be installed as the power demands require. Under the plans of the International Improvement Commission four power plants are to be erected, with a gross estimated development of 140,000 horsepower. The returns from the ballots on election day showed a tremendous majority in favor of the issuance of the bonds. Not only is the state of Illinois interested in this development, but the entire West has congratulated itself upon the active interest which the voters of Illinois have taken in this issue, because it required not only a majority of the votes cast to be in favor of the bonds, but every vote that was not cast for or against it counted against the issue.

The great publicity which has recently been given to the conservation of our waterpower resources, to the canalization of our barely navigable rivers, and the necessity of the development of our inland waterways and our cheaper sources of power going hand in hand, has directed the attention of all thinking men to this problem, and it is only through this publicity, which has been secured through the open-minded and forceful co-operation of the press of the country, that the result announced herewith has been possible.

CAN WE USE A NEW COMBUSTIBLE?

For years the dream of inventors has been the production of power by some direct means of breaking down the chemical associations which render inefficient, to a high degree, so many of our present-day methods of utilizing the potential energy of our known combustibles. Great effort upon the part of assiduous workers, and the expenditure of large amounts of money, have resulted time after time in apparent failure, and today it would not appear that we are not much nearer the solution of this problem than we were several decades ago. Within the last few years there has not been chronicled much in the way of development in this direction, so that the suggestions made by Mr. Edward C. Warren, in the current issue of *The Engineering Magazine,* in an article entitled "Fuel for Power Generation," should excite considerable interest.

Mr. Warren delivers himself of the postulate that "power costs nothing." By this he means that we should secure our means for the provision of energy, not by any elaborate process of combustion, which apparently wastes the material involved, but we should use our combustibles under much the same conditions as we utilize the power of the waterfall; that is, by simply taking as a natural thing the energy-producing condition, and being obliged to expend money only for the harnessing of the natural element.

It is ingeniously pointed out that Nature, in bringing back to the watershed in the form of rain and dewy precipitation the source of power which has already caused the mill to grind and the water turbine to turn, points the way to the short-circuiting of the ordinary cycle of the utilization of our known combustibles. Carbon and hydrocarbons, our most popular forms of fuel at the present day, in combination with oxygen, form a combustible material. After the generation of heat the atom of carbon unites with its two atoms of oxygen, and ages are necessary to bring about the reorganization of these elements, through the evolution of plant life, so that the matter which is being used up today will not be available again for the present generation.

Why not use hydrocarbon for fuel? This is the leading question in Mr. Warren's communication. Its symbol is H, its chemical equivalent is 1, its heating value in combustion with oxygen is 60,000 British Thermal Units per pound. What are the special qualifications of hydrogen as a fuel? Its heating value per pound is four times that of the best coal. But where are the natural deposits or supplies of hydrogen? All of the foregoing belongs to Mr. Warren. He is of the opinion that the supply is inexhaustible, and that its natural cycle through the processes of isolation, combustion and re-isolation is so short as to render feasible a continuous re-use of the same volume of fuel substance. It has the practicability of perfect combustion, without ash, smoke or soot, without vitiating gases; for the sole product of combustion is water. The combustion being perfect, the product of combustion is aqueous vapor, immediately condensable and susceptible of ready decomposition, and yielding ready to hand, not merely the original volume of hydrogen, but the oxygen requisite for its immediate recombustion. With this statement the author concludes that we shall derive our supply of both hydrogen and oxygen from the waters of the earth, and that we shall simply insert or interpose our mechanisms or harness in a natural fuel cycle, and derive unlimited supplies of power by intelligently short-circuiting a naturally simple and expeditious cycle of one of Nature's elements.

So far so good. The elucidation of a practicable and commercial means of isolating the constituent elements of our projected combustible is left for another time and place. The matter is worthy of investigation. Possibly there are flaws in the author's reasoning. If so, we shall be sure to hear of them in the near future. He says that the power user has never asked the chemist whether this were possible, and that because someone long ago instituted the use of certain forms of combustibles, and let it go at that, that we have been content to plod along the lines laid out for us and utilize in wasteful fashion that which in the nature of things must some day be materially exhausted. The subject is of great interest, and the fuel problem of the future is pregnant with the possibility of development. Mr. Warren's further ideas on the subject will be watched for and welcomed.

A DIFFICULT PHASE OF POWER SOLICITATION.

In most large communities where the central-station power business has shown a gratifying growth in the past few years there exist a number of private plants which for one reason or another are extremely hard to convert to the operating company's service. The chances are that each of these isolated installations has been approached at least three or four times by representatives of the central station, with the apparent net result of making little or no progress. When a rival interest like a local gas company is hard at work to keep out the electric motor, the problem of securing this business is rendered doubly difficult. To give up the attempt to secure the business, however, is poor policy, and the central station should never erase the name of an isolated plant from its list of prospects. Sometimes it may be a year or two before any chance occurs to introduce the subject of power purchase to the isolated-plant owner, but the probabilities are that if the conditions are watched with keen attention, some day there will be an opportunity to install at least a small motor-connected load as an entering wedge. Unless the plant is operated with more than ordinary skill it is almost certain to fail to give continuous service at some critical period, and even if there are no interruptions, it is probable that the total operating costs, if rigorously set down, would surprise the owner, especially where new types of equipment are in service.

Close observation of the growth of the isolated-plant-owner's business, the need of fresh space in his store or factory, occurrence of accidents, probable excessive cost for repairs, troubles with labor in the engine or fire room, complaints of other parties regarding noise, smoke or dirt, with the possibility of interesting him in new designs of motors or lamps specially adapted to his conditions, should all be kept in mind. The acceptance of some famous rush order for a manufactured product may require more power to prevent severe overloading of the existing apparatus. Or again, the motor drive may permit the rearrangement of machinery in such a fashion that the efficiency of production will be increased many per cent. Conditions alter in the isolated plant, as in every other commercial agency, and by never ceasing to watch for a turning point in affairs it is probable that the central-station man will in time have some chance to show what he can do.

In some cases where the power rates offered by a central station are lower than those of a rival gas company, the owner has been known to advance the argument, that by installing tungsten lamps he can reduce his output enough to give a good margin for future power requirements. The effect of so reducing the load on a gas-engine equipment of low power is at once apparent to an electrical engineer, but it needs to be emphasized in a way that the private-plant owner will not fail to appreciate. Any notable reduction in load on a small prime mover means a serious loss in economy, which can often be figured pretty closely in terms of dollars and cents. When a local gas company is obliged to pay the cost of installing a gas-engine equipment in an isolated plant, the price being gradually paid back by the owner on installments along with his monthly bills, it is clear that electricity is pushing matters close to the wall. In order to gain a good customer of this sort there would seem to be no reason why the central station could not adopt the same plan with regard to motor installations in exceptionally hard locations. It will pay to emphasize to the owner facing such a proposition from a gas company that by the time the gas engines are paid for the depreciation is certain to have rendered them worth but a small percentage of their original cost, unless the most expert skill is available for the care of these small units.

THE PENNSYLVANIA ELECTRIFICATION.

From time to time announcement has been made that various commissions had under way the study of plans for the electrification of the terminal zone of the Pennsylvania Railroad. The great expansion of the local service of this transcontinental system by reason of its tubes under the Hudson River, Manhattan island, the East River, and in Long Island, in connection with the Long Island Railroad, has made imperatively necessary the utilization of electricity as a means of propulsion. It is with satisfaction therefore that we read the announcement that an appropriation of $5,000,000 has been made to begin the work of electrification, and that a contract has been let to a large manufacturing company to lay down the initial electrical equipment.

American Electrochemical Society.

Fourteenth General Meeting, New York, October 30-31.

The fourteenth general meeting of the American Electrochemical Society was held in the city of New York on Friday and Saturday, October 30 and 31, 1908. The session of Friday was held in the chemistry building of the College of the City of New York.

President Edward G. Acheson of Niagara Falls, N. Y., called the meeting to order on Friday morning at 9:40 o'clock.

The first paper considered was "The Use of a Mercury Cathode in the Determination of Metals," by A. Harold Porter and Francis C. Frary. The conclusions reached in this paper are:

1. The electrolytic determination of zinc in a mercury cathode gives low results, due to loss of both zinc and mercury in the process of washing with alcohol and ether.

2. Pure mercury does not lose weight appreciably when washed with water, alcohol and ether, nor by liberation of hydrogen on its surface even at high temperatures (100 degrees).

3. The loss in weight during washing seems to be peculiar to zinc, since copper amalgam shows no signs of it, and the determination of copper by means of mercury cathode is quite satisfactory.

The discussion was opened by Dr. H. E. Patten, who requested that the exact voltage, current and current density used in these determinations be given in the final report on the subject.

Walter T. Taggert then discussed the subject at length, giving details of the methods he had successfully used and precautions that must be observed to get reliable results.

Prof. J. W. Richards also spoke critically about the paper.

The second paper, entitled "The Passivity of Nickel and Iron," by Dr. E. P. Schoch, was read by Dr. Patten. The author was led into his study of these phenomena while working on the potential of the reversible electrode. The paper was briefly discussed by W. D. Bancroft and Dr. Patten.

A paper on "Chemical Energy," by J. E. Mills, was then presented. In this paper the author seeks to ascertain the ultimate origin of energy liberated in a reaction and show its amount varies under different conditions. The argument is based on the reaction occurring when the gases hydrogen and oxygen combine to form water. Among the conclusions reached is one that the attractive forces, whatever their nature, whether chemical, molecular, magnetic, electrical or gravitational, which proceed from a particle are definite in amount. If this attraction is exerted upon another particle the amount of the attraction remaining to be exerted upon other particles is diminished by an exactly equivalent amount. The relationship between chemical and electrical forces is considered in its bearing on the conductivity of substances. This paper was briefly discussed by E. Durant and L. F. Guttman.

Prof. Charles Baskerville, director of the laboratory of the College of the City of New York and chairman of the local committee that had arranged for the meeting, then presented President John H. Finley of the College of the City of New York.

President Finley welcomed the society in a pleasant speech, in which he grew reminiscent of the chemical and general scientific training he had received in his early college days and contrasted it with the advances that had been made in the teaching of science at the present time.

G. A. Hulett then presented his paper on "Equilibra in Standard Cells." It was discussed at length by Dr. W. D. Bancroft, who argued that the basic salt cannot coexist with mercury sulphate except at one concentration of the sulphuric acid.

A paper was then read by G. W. Morden on "The Formation of Nitric Acid from Air by Means of Low-voltage Direct Current." The discussion was participated in by A. L. Cushman, F. A. Lidbury, L. F. Guttman and the author. It related mostly to the influence of the portions of the arc, from which the gases were removed, upon the composition of the gas. As the arcs were only from three to six millimeters in length, with four millimeters average, conclusive results on this point were not obtained.

FRIDAY AFTERNOON SESSION.

At the afternoon session the first subject considered was introduced in an informal address by Prof. A. F. Ganz on "The Corrosion of Underground Structures." He said the corrosion of underground metal surfaces may be divided into two general classes, first, corrosion due to purely chemical causes or ordinary rust; second, corrosion due to electrolysis from stray electric currents. Whether or not all chemical corrosion is also electrolytic in its nature does not alter this decision from the standpoint of the practical engineer.

When an electrical engineer is called upon to make an electrolytic investigation of, say, a pipe system, he may have two distinctly separate problems to solve. The first problem is to determine the electrical conditions of the metal system, that is, the potential at various parts of the system with reference to the surrounding ground, and with reference to other underground metal. He must determine the current flowing, and if possible the point where the currents leave the structure for the ground, because these are the points where corrosion may develop. If in this investigation he finds that the system is in electrolytic danger, then his second problem is to recommend some method whereby the danger can be substantially removed and at a reasonable cost, which is always an important element.

Attention was called to a wholly incorrect method which has been used in this country, and has been published in a certain class of electrolysis reports, in which the potential differences are measured between pipe and rail, and the earth resistance is measured at the same points, or to be more correct, the resistance is measured between the pipe and rail, which is called the earth resistance between these two points. This resistance is then divided into potential difference, and the current so found is stated to be the current flowing between these points. This is repeated, every block for a given system, and the currents are added up, and the total current so found is stated in all seriousness to be the current which flows in that street between the pipe and rail. The absurdity of that method should be clear to all, and every member of the society was asked to take every opportunity to show up in every possible way such fallacious methods, because they have done a great deal of harm.

The question has often been asked whether the steel foundations for bridges and buildings which are usually imbedded in concrete are also suffering from corrosion, due to these stray railway currents. These metallic underground structures do not have the same opportunity of picking up currents from any extended area. There is one case, however, where such structures may be in serious danger. If a pipe comes in contact with such a structure mechanically, as is sometimes the case, and the pipe is carrying current, it is positive to the surrounding ground. Under these circumstances a current picked up over an extended negative piping area may be delivered to the metallic underground structure and, leaving it, produce corresponding electrolytic corrosion. In a number of instances special precautions have been taken to insulate the steel foundations of structures from piping systems, and it seems to be a safe precaution to take in all cases.

Where dangerous conditions in an underground system are found, the second problem that the electrical engineer has to meet is to recommend proper preventive measures which will not be prohibitive in cost. It is there that the electrical engineer can get the most help from the electrochemist. If the underground metal system is continuous it may be connected to the negative return system of the electric railroad. That is, however, a matter which invariably greatly increases the current flow on the pipes and produces other dangers. For instance, at a high resistance point, which may develop in the joint, the current may shunt around such a point and produce corrosion. The greater danger, however, lies in the danger that such a bonded system is to all other underground metal systems. If one connect one piping system to the negative bus-bar, one renders it highly negative to all other underground metallic structures and introduces current flow to this pipe system, and thereby this system becomes a part of the railway return circuit and a party to any damage that may be done.

Professor Ganz then submitted five questions which embodied the points that he wished to open up for general discussion. The first related to the activity or passivity of iron in street soils. As Professor Harber of Karlsruhe, who is investigating this question pretty thoroughly, concludes that under the ordinary soil conditions iron is always in the active state, that practically the passive state does not exist in underground metal systems, the question was raised what can be done to render active iron passive. Some one had suggested to cover an underground pipe with lime for that purpose. Question No. 2 referred to means for identifying the causes which have produced a given corrosion. As a practical example of this, Professor Ganz showed a number of lead cable and pipe samples that had been submitted to him to find out whether they were pitted by electrolysis. Question No. 3 was, "Can we protect an underground metal structure, such as a piping system, by coating it with an insulating material in such a way as to prevent current entering or leaving that pipe?" Question No. 4 related to the breaking up of the continuity of underground metallic structures, as, for instance, by the use of insulating joints, the point being whether this method can make such a pipe system substantially safe from electrolytic corrosion. The last question was, "What is a safe current density per square foot of pipe surface for current leaving for ground?"

Dr. Allerton L. Cushman called attention to corrosion of plates of steamships and of pipe lines remote from electric circuits that was as destructive and of the same nature as that known to be due to electrolysis by railway return currents, and argued that this corrosion is due to electrolytic action whether an extraneous current is present or not.

Maximilian Toch corroborated what Dr. Cushman said with reference to the corrosion of these pipes and plates. He said it is settled in his mind that all corrosion is an electrolytic function. That is the fundamental basis of it. He believes that stray electric currents aggravate this corrosion. With reference to coating gas pipes with asphaltum, it was found by a natural gas company that built a pipe line from Peoria to Chicago and coated it with asphalt about a quarter of an inch on the inside and half an inch on the outside, that since fuel gas is a powerful solvent for all bituminous compounds, in a very short time the entire pipe was so clogged up with the dissolving bitumen and bituminous compounds that it became useless, so that bitumen or asphalt or tar should be excluded from the interior of a gas pipe.

Professor Ganz said the distinction he made in his remarks was not a distinction between chemical corrosion and electrolytic corrosion, but a distinction between corrosion produced without outside electric currents and corrosion produced with outside electric currents, which is an engineering problem. He knew of some private corporations owning very considerable underground pipe systems—one in particular where a single pitting in a pipe caused a damage of $50,000 indirectly, and these companies will gladly spend any reasonable amount of money if a method can be devised for permanently protecting such important pipes. He did not propose this method for the distributing system for water or gas in any city where the whole system would have to be treated, but there are many cases of importance, such as high-pressure lines, where generally any reasonable expense will be gladly paid if permanent protection can be assured.

Carl Hering believed that current cannot leave the pipe for the soil, that is, if there are liquids in the soil, without causing corrosion. There is one method by which a pipe might possibly be protected. If there is a pipe from which it is known that current is going to flow out, by attaching to the pipe metallically a block of zinc buried in the ground, any current which is bound to go into the ground would prefer to leave through the zinc than through the pipe, because it takes less voltage, and as long as the zinc is there and is not destroyed the pipe would be protected, the zinc being replaced after it is consumed. As to coating pipes to prevent corrosion, while this may prevent it, where it keeps the electrolyte from coming in contact with the pipe, such coatings are very apt to be injured in spots, which means that the corrosion instead of being spread over a large surface will be condensed into a small surface, and will therefore do all the more damage, because if the current is condensed on a small area it will eat through the pipe in shorter time. What current density is a safe limit should be answered by saying definitely none. That is, no current density leaving the pipe is safe, because one never knows whether it is going to leave from that area or to be confined to a quarter of a square inch. In a number of cases, when a pipe was in danger at a certain place and was protected there, it was thought that that was sufficient. To Mr. Hering this seems very incorrect reasoning, as it simply shifts the danger point to another place.

R. H. Gaines cited a case of a pipe line near the city of Rochester, where all the elements of corrosion showed that it was simply due to stray currents, yet no potential difference could be found with the millivoltmeter between the pipe and the ground, and there was known to be no source of commercial electricity anywhere in the neighborhood.

The discussion of Professor Ganz's subject was concluded by I. L. Roberts, W. D. Bancroft and S. S. Sadtler.

A paper on "Correct Methods of Measuring Stray Currents," by Dr. Clayton H. Sharp, of the Electrical Testing Laboratories, New York city, that was on the programme for Saturday morning, was then taken up. Dr. Sharp had no written paper and presented his views on the subject verbally. The chief point to be found out is whether there is at any point any considerable amount of electric current leaving the pipes. The problem is easily stated, but it is not so easily answered, for the reason that in general it is not possible to destroy the continuity of the system of piping in order to insert instruments, and it is not possible to insert instruments in the surrounding soil without disturbing the conditions as they actually exist in practice.

The electrical instrument which is used chiefly in investigations of this nature is the voltmeter or the millivoltmeter, and this instrument has sometimes been used with very distressing and alarming results. However, one can gain a great deal of information by the proper use of the voltmeter. One may feel quite sure that where the trolley line and other structures are positive in potential with respect to the pipe, the pipe is quite safe. Also, that where the pipe is positive to other structures, that it may be in danger. It is wrong to conclude that, because it is so, that it is actually in danger—for instance, it may be quite well insulated by passing, say, to dry sand or gravel from moisture, so that the discharge of electricity from the pipe to the soil electrolytically is prevented.

Having determined by the use of the voltmeter what the possible danger areas are on a system of piping, the next step is to determine the current flowing on the pipe, and especially the current leaving the pipe. To determine this the most satisfactory method would be to interrupt the electrical continuity of the pipe by inserting an insulating joint, and then spanning that joint with wires passing through an ammeter and measuring directly. This, however, is often not feasible. Consequently, it is necessary to revert to indirect methods for measuring the current. The principal one is by means of the fall of potential on the pipe. Electrical connections are made at two points on a single length of pipe to a sensitive low-reading voltmeter, preferably one of high internal resistance, and the indications of this voltmeter or millivoltmeter are read over a sufficient period of time to show what the average condition of the pipe is. Then, if the resistance per unit length of pipe is known, it is possible to interpret these millivolt readings in terms of amperes of current flowing on the pipe. The difficulty with this method is the determination of the resistance per unit length of pipe. Now pipes are made in standard sizes and of material which varies a good deal, but which has fairly fixed average values of resistance, and since it very often happens that one is concerned only with rather rough quantitative values, one assumes from the known dimensions of the pipe, and the known resistances of the material, the resistance of the length of pipe which is being dealt with, and in this way makes the interpretations of current.

It is possible sometimes to get at a rather better value by resorting to a procedure which consists in attaching to the pipe heavy leads that are brought out and connected with an ammeter. The potential difference between two portions of the pipe close to the place where these heavy leads are brought out is measured when these leads are not connected, and again when they are connected through the ammeter, and at the same time the value of the current, as shown by the ammeter, is measured. In the second case, when the ammeter is in circuit, the potential difference as shown by the millivoltmeter will be less than in the first case, and the reduction of voltage due to drawing a certain measured current from the pipe, gives an indication of the resistance of that length of pipe. For instance, if we find that by connecting the heavy leads we reduce the potential difference between the two points on the pipe to one-half of its former value, then we know surely that the original current flowing through the length of pipe was twice what the ammeter indicated.

However, the problem not only involves the determination of the current flowing in the pipe, but more particularly the current which is escaping from the pipe. How shall we determine that? The only way Dr. Sharp knows of doing that without seriously disturbing the normal conditions of the pipe is by taking some potentiometer measurements of the current flowing on lengths of pipe separated from each other by suitable distances. This may be taken by suitable instruments, and observers reading at the same time, or by sensitive and accurate recording instruments, which are also obtainable for this purpose. The interpretation of these results will give at least a rough measure of the current which is leaving the pipe at points between.

We can also get some indications of the probable escape of current from the pipe by exploring the electrical condition of the soil in its vicinity. If we start from the pipe and find a continuous fall of potential as we go from point to point away from the pipe, the indications are that current is flowing along such lines, and that these lines are stream lines of electricity. In making measurements of this kind it is advisable of course to use electrodes not subject to error due to polarization, that is, electrodes in zinc-sulphate solution, or similar electrodes, and make the measurements by a method which does not draw any current so as to eliminate resistance drop at the point where the electrode is inserted in the soil, that is, some form of potentiometer is indicated as the proper one here. Professor Harber's earth ammeter, as it is sometimes called, is also used for this purpose.

The discussion of Dr. Sharp's address was rather brief, Dr. Carl Hering questioning the value of the shunt method. Dr. Sharp admitted that it was satisfactory only with pipes of moderately high resistance.

The paper on "Electrolytic Corrosion of the Bottom of Oil Tanks," by A. A. Knudson, was then read and discussed by S. S. Sadtler, Carl Hering, A. L. Cushman, C. F. Burgess, W. H. Walker and J. W. Richards.

A paper on "The Function of Oxygen in the Corrosion of Metals," by W. H. Walker of Boston. It was not discussed.

Professor Baskerville was then called on to make an address. He spoke at length on the equipment and general educational work of the College of the City of New York, and particularly of the methods used in its chemical laboratories.

"The Theory of Electrolytic Paints," by Dr. W. D. Bancroft, was next presented, and its reading was followed without further discussion by "Simple Methods for the Prevention of Electrolytic Corrosion," by Prof. Maximilian Toch.

A. A. Knudson added another question to those that Professor Ganz had presented, which he set before the convention in the following words: "I have in mind two wrought-iron water pipes which are undergoing corrosion probably from chemical processes. These pipes run in a creek partly submerged and are negative to the soil at that point. There is a current of electricity flowing through it, sometimes reaching seventy-five and eighty amperes. I wish to ask if this current of electricity flowing through these pipes tends to assist the electrolytic action of corrosion on the surfaces from the chemical effect?"

Prof. Albert F. Ganz inquired if it it is necessary first to coat an underground pipe with a solution paint before applying the coating which will keep away the water. Mr. Toch explained that it would not be necessary to paint the pipe, although it is best to apply an insulating hydrocarbon paint, pouring half-neat cement around the pipe. This would be as cheap and better than pitch.

Allerton L. Cushman explained that the object of the inhibitor is to keep in contact with the surface of the steel a slightly soluble compound so that if any water gets through the excluding paint surface, upon reaching the steel the water must contain in solution some protecting derivative of iron. It was hoped, he said, that the scheme would work out practically, as theoretically the idea seemed to be all right.

Mr. Toch replied that in actual practice, when a beam or a billet is coated at the mill and transported, great chains being wrapped around it to hold and support it, besides the other surface injury to which it is subjected, no protective coating of .001 of an inch in thickness has been made that will withstand these attacks.

SATURDAY MORNING SESSION.

The Saturday morning session was held at the Chemists' Club on West Fifty-fifth street, and President Acheson, after calling the meeting to order, announced the paper on "The Lash Steel Process and the Electric Furnace," by F. A. J. FitzGerald, consulting chemist, Niagara Falls, N. Y.

Henry D. Hibbard spoke of the great advantage of the electric furnace in the production of heat without oxidation. When steel is made in the open hearth furnace, all the effects of oxygen are produced, the mingling of the carbon and silicon is carried out by oxygen, and in fact oxygen is the great servant used in produsing the results, but oxygen, while an excellent servant, always lies in wait to give all kinds of trouble, if one does not know how to handle it at the latter end. The oxygen must be fairly eliminated from the metal or the result is poor. In the electric furnace heat can be produced without oxygen, and from a steelmaker's point of view the process of making steel by such a furnace is simplified more than one can realize.

Prof. J. W. Richards said that there are two ways of making steel—one is simply to melt the ingredients together, and the other is to oxidize the pig iron so as to eliminate the impurities and get down to steel. These two processes require essentially different kinds of apparatus, for the reason that in the melting process it is simply a case of melting. In the oxidation process it is largely a case of having surface to oxidize the bath by means of the iron ore which is added. These two requirements are going to give rise to two different classes of furnace, each best adapted for its purpose. As to the question of losing iron in slag, that is not such a very serious one, because in ordinary open hearth processes there is considerable loss in slag. Electrochemists should not think that a process to be commercially successful must reduce the iron in the slag to a low point. There are open hearth furnaces running making steel successfully where they lose something like fifteen or twenty per cent of iron in the slag, but yet are commercially successful. The third point that Professor Richards made is that the electric furnace is being developed very largely by electricians and electrochemists, who in many cases are not experienced steel men, and the ideal combination is to get the experienced steel man with a first-class electrochemist to work on the proposition. Where a firm which is experienced in making steel secures the assistance of an electrochemist or an electrometallurgist to do the electrical work for them, the combination succeeds very nicely.

W. S. Landis contended that as he understood the Lash process, it is intended particularly for the reduction of iron ores and the final production of steel directly from them in the same operation, and it seemed, therefore, that the loss of iron in the slag is rather an important item.

At the request of W. H. Walker, Mr. FitzGerald described the Lash process as consisting in making an intimate mixture of the cast iron, oxide of iron and carbon. The cast iron is in the form of bars, or shelf pig iron, and is supposed to act as a carrier for the carbon and also some metalloids contained in it; it undoubtedly acts as a reducer. The process seems to be extremely simple and has been carried out on a very large scale, many hundreds of tons of steel having been made in the open hearth process, showing economies over the regular practice. In the Lash process a much larger percentage of ore can be used and in the open hearth furnace there is no difficulty in reaching a yield of ninety-four per cent, which means a loss of six per cent in the metallic contents. The method of working has been to have a blast in the furnace and then to add the Lash mixture. In the electric furnace, in the experiments made, there was about sixty per cent of ore, about twenty-three per cent of cast iron, and the remainder fluxes and carbons.

A paper, entitled "The Latent Heat of Vaporization of Zinc," by W. McA. Johnson, was then read. It was discussed briefly by Dr. Hering and Professor Richards.

Dr. Carl Hering next presented a paper on the subject, "Heat Conductance Through Walls of Furnaces." It related to methods for decreasing the loss of heat through the walls of electric furnaces.

P. M. N. Dennie spoke of the value of a gas envelope about a furnace in increasing its efficiency. C. F. Carrier, Jr., discussed Mr. Hering's constant K or coefficient of conductivity and regarded it rather as variable. J. W. Richards said that in studying recently the heat radiation from a certain sort of furnace it was shown by experiment that after a certain wall thickness was reached there was no more use in putting on protecting material outside, as the increased effect from the additional material was practically negligible. Others discussing the subject were H. D. Hibbard, J. C. Parker, F. A. Lidbury and W. S. Landis.

The next subject on the programme was an address on "Utilization of Power Stations for Electrochemical and Electrothermal Processes During Periods of Low Load," by E. A. Sperry of Cleveland. Mr. Graves, of the Brooklyn Edison Company, then read the paper on "Electrochemical Loads and the Central Station," written by John Meyer of Philadelphia.

The discussion on these topics was opened by President Acheson, who, speaking of the carborundum furnace, said the duration of its run is thirty-six hours, so that it would overlap all the high points and valleys, and it is not, therefore, available for central-station work, but there should be many industries that could be fitted in. Probably not so largely in the case of the electric furnace, because after the furnace is once fairly heated up it is not well to let it go out because the initial heat in warming up the work represents a large amount of energy.

Edward R. Taylor said that there are many electric furnaces capable of intermittent work in that respect, but of course not to as good advantage as though running continuously for twenty-four hours. It would not be advisable to shut the current entirely off during the peak load. For example, if the furnace were run twelve hours and then stopped twelve hours, it would barely get started again. On the other hand, on the peak load the furnace could be kept hot, and just below the point of production, and then when the valley load came an increase of power could be put on, and the production proceed for twelve hours. The current could probably be cut off best for the two or three hours of the peak load.

Dr. Carl Hering declared that the energy required for heating up a furnace is generally so great that it is doubtful whether it would pay to use furnace processes intermittently, unless the loss during the non-working period can be made very small. He thought, therefore, that the more probable field of usefulness for spare current would be for electrolytic processes, which can be more readily stopped.

W. E. Wells thought that if the electrochemical interests could get together with the central-station men, arrangements might be made whereby during the greater portion of the year current could be furnished continuously; during another portion of the year current could be furnished continuously except on Saturday nights, and during another and very short portion of the year, amounting to not more than forty-five days, current could be furnished continuously, excepting a one-hour peak, or a peak ranging from one and a half minutes to five minutes. It may not be generally known, but the last twenty-five per cent of the capacity of a large number of electric-light stations is used only one hundred hours per year. That twenty-five per cent of capacity could be used the other 8,000-odd hours to a very good advantage.

Lawrence Addicks said that for copper refining plants the price of current would have to be very low to be attractive, as the process is very sensitive to changes in conditions, an alteration of even ten per cent in current density at different times of the day disturbing seriously the silver and gold alloys.

C. F. Carrier, Jr., believed there is one factor that is apt to be overlooked in this question. He had found as the result of a complete calculation of a plant for making metallic sodium that was to be located near a central power station that, if the central power station made any money, he could not make any money, and, if he made any money, the central power station could not make any money.

G. M. Kibbe argued that while waterpower is cheaper in most instances than power from any other prime mover, a location at a remote waterpower may still make the production costs higher than a location near a central station at tidewater, for instance. Tidewater shipping facilities, cheap labor and a nearer market for finished products may more than offset the economy of waterpower.

Prof. J. W. Richards referred to an electric-furnace plant in Switzerland which runs one heat in the morning and one in the afternoon, and is then shut down for the rest of the day. Such plants could arrange to make another heat, so as to fit in with hours that would be satisfactory to the central-station managers. There are also some electrolytic processes which can be absolutely stopped for a certain number of hours, not run on light load, but more easily stopped entirely for four or five hours, and then started up again without practically any hindrance at all. It would be well for electrochemists, in considering different kinds of processes, to consider whether the process cannot be modified, or practically stopped, to fit in with the number of hours when current can be got at the cheap rate.

P. M. N. Bennie said the large generating companies at Niagara Falls are also acquainted with the load-factor problem, and they have been looking for the same solution right among these works, and they have not found it. He thought perhaps there has been a good deal of dreaming on this idea of getting an intermittent load and making it a success. There has been a great deal of work done on it, but there has not been any solution of it.

Lawrence Addicks believed that the relative importance of the power cost in the electrochemical industry to the total cost is not fully understood. There is an impression that it is a much larger item. From his experience in the copper-refining business the power runs at about twenty-five per cent of the cost, so that a saving in power may easily be outbalanced by other factors..

Others discussing the subject were Messrs. FitzGerald, Hibbard, Graves, Kohn, Wells, Breed, Sadtler and Sperry.

Edward R. Taylor was then called on to outline the objects of the appointment and the work of the national conservation committee.

On motion of Dr. Hering a vote of thanks was tendered to those who had participated in making the arrangements and promoting the success of the convention. The meeting then adjourned.

Among the entertainment features provided were a luncheon and organ recital on Friday noon at the College of the City of New York, a dinner at Reisenweber's on Friday evening and a smoker at the Chemists' Club on Saturday evening. On Saturday afternoon a visit was made to the Balbach Smelting and Refining Works at Newark, N. J., where the process of smelting and refining of lead, copper, silver and gold were inspected with much interest.

Electrical Ordinance for Atlanta, Ga.

What fire underwriters and electrical men in general regard as a model electrical ordinance, has just been adopted by the city council of Atlanta, Ga. The ordinance provides for a board of electrical control and regulates the construction and installation of electrical work and equipment. It goes further than almost any set of regulations previously framed anywhere for this purpose, and if properly observed should reduce to a minimum the hazard from improper wiring. A digest of the text of the ordinance is given here. The ordinance was framed by A. M. Schoen, chief engineer of the Southeastern Underwriters' Association, at the request of the city authorities.

The ordinance creates a board of electrical control, to consist of the chairman of the committee on electric lights, telegraph and telephones, the city engineer, the chief of the fire department and the chairman of the committee on electric and other railroads, the first named official to be the chairman of the board. It is the duty of the board of electrical control to have inspected all electrical construction, installations and equipments of any kind which it has the power to order removed, repaired or rebuilt, when, in the board's judgment, life or property will be better protected thereby. The board is charged with the duty of enforcing all laws relating to electrical energy and construction, and is empowered to pass upon the ability and responsibility of applicants to do electrical contracting in the city of Atlanta.

In January of each year the city council is to elect a competent man for the position of superintendent of electrical affairs, who is to receive a salary of $1,800 per annum and be subject to the orders of the board of electrical control. The superintendent of electrical affairs regulates and determines the placing of wires or other appliances for electric light, heat or power. In the discharge of his duties the superintendent is privileged to enter any building, manhole or subway, or to climb any pole, for the purpose of examining and testing electrical appliances. He has also authority to compel the removal of superfluous poles which may impede travel. The superintendent of electrical affairs inspects, approves and issues certificates of satisfactory inspection of all wiring. With the aid of the officers of the police department who report the operation of lights in the district, he has general supervision of city lights, requiring all concerns furnishing lights to the city to comply with the terms of their contract.

All electrical construction, material and appliances must conform to such special rules as may be adopted by the board of electrical control, and to the rules and requirements of the National Board of Fire Underwriters. No wiring or alteration in wiring for light, heat or power, or increase in the load carried is to be made without a written permit from the superintendent of electrical affairs.

The superintendent has authority to cut off the current in case of failure to comply with the ordinances. The use of metal conduits only is permitted for wiring buildings within the fire limits.

Failure to comply with the ordinances or an order or request made by the electrical superintendent by the authority of these ordinances is punishable by a fine of not less than $25 nor more than $100 for each offense, or thirty days' imprisonment. Before engaging in electrical construction it is first necessary to obtain a license, the fee for which is $25, although an establishment employing a man of electrical knowledge and experience may have the employe take the examination and be granted a license to do electrical work only in the establishment or building in which he is employed, upon payment of a fee of $5. Any person, firm or corporation found doing electrical work in the city of Atlanta without a license is subject to a fine of $100 or imprisonment for thirty days, or both. Licenses are for one year only and are not transferable.

Brooklyn Modern Science Club.

The Modern Science Club, 125 South Elliott Place, Brooklyn, N. Y., under whose auspices illustrated lectures on civil, electrical, hydraulic, mechanical and marine engineering subjects are held, announces the following forthcoming numbers on its fall programme:

November 10—L. J. Wing, of L. J. Wing Manufacturing Company, "Practical Results in Forced Draft Installation."

November 17—William T. Donnelly, M. E., "Transportation by Water."

November 24—C. J. Simeon, of the Avery Scale Company, "Automatic Scales in Modern Industries." With particular reference to the weighing and handling of coal.

Saturday, November 28, will be the date of a special lecture and general discussion upon the subject of "Patent Office Experiences."

Use of Electric Power for Safety in Mines.

The United States Geological Survey has issued a report on the prevention of mine explosions, submitted by three foreign experts, Victor Watteyne, inspector-general of mines, Belgium; Carl Meissner, councilor for mines, Germany, and Arthur Desborough, his majesty's inspector of explosives, England.

Among the recommendations of the report are these on the use of electricity:

"Electricity in mining operations offers so many advantages and has been so generally adopted that no reasonable objection can be made to its use under proper restrictions. The electrical equipment, however, should be installed, maintained and operated with great care, and so safeguarded as to minimize danger from fire or shock. The fact that the effectiveness of some insulating materials is soon destroyed in most mines should not be lost sight of.

"We recommend the following precautions: For distribution underground the voltage should not exceed 650 direct current or 500 alternating current, these voltages being intended for transmission to machinery operating at 500 volts direct current and 440 volts alternating current, respectively. Even lower voltages are preferable. The trolley wires should be installed in such manner as to render shocks least likely—that is, placed either high enough to be beyond easy reach or at one side of the track and properly protected.

"Where current at a potential of more than 650 volts is employed for transmission underground, it should be transmitted by means of a completely insulated cable; and where a lead or armored covering is used, such covering should be grounded.

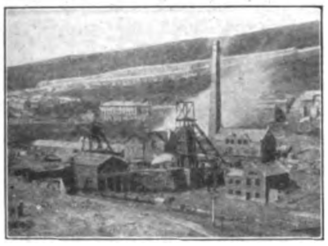
"In all mines having electric installation special precautions should be taken against the setting on fire of coal or timber. Inclosed fuses or cut-outs are recommended, and each branch heading should be so arranged that the current may be cut off when necessary.

"No live electric wire should be permitted in that part of any mine in which gas is found to the amount of two per cent.

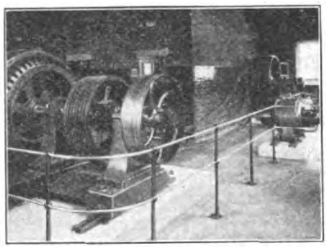
"In all mines producing gas in dangerous quantities, as indicated by a safety lamp which will detect two per cent of gas, the working places should be examined for gas by a qualified man using such a lamp immediately before any electric machine is taken or operated there."

ELECTRIC POWER IN THE COLLIERIES OF SOUTH WALES

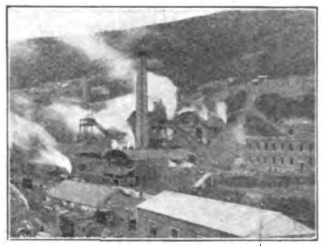
BY A. H. BRIDGE.



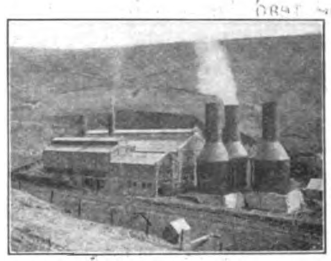
NOS. 8 AND 9 PITS, TYLORSTOWN.



NO. 9—FAN HOUSE INTERIOR.



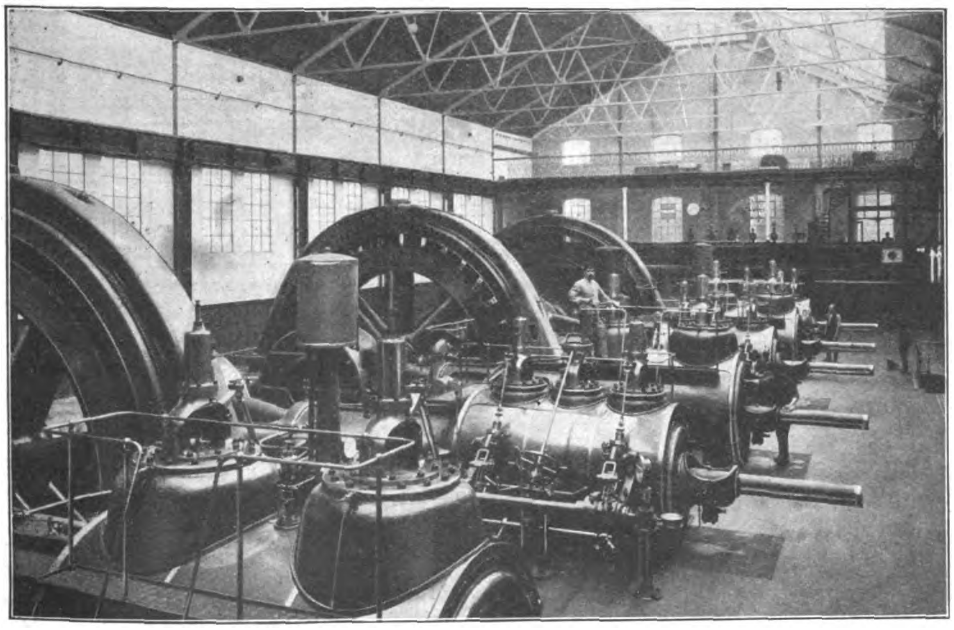
NOS. 1 AND 5 PITS, FERNDALE.



POWER STATION.

During the last few years the South Wales district has been the most fruitful one in the United Kingdom for the electric mining engineer, for in it quite a number of important installations have been put down for some of the principal colliery owners. It is reasonable to expect that the next few years will be even more satisfactory in this respect, both in the matter of new plants and in the extension of those already down. Two things of interest as leading to this anticipation are matters of general comment just now. One is the almost certain extension of electrical application in mines now that the demands for heavy output of coal which have been a remarkable feature of the last year or so, have lessened somewhat, giving a favorable opportunity for bringing the equipments of the mines up to date. The other is the greater application of electricity that is expected to follow as one result of the proposed, but at present deferred, legislation for a miners' eight-hour day.

It will be remembered that it was in the South Wales district that a large power company carried on extensive operations supplying large power users from several generating stations, but came to such a disastrous experience, ending in financial breakdown, loss to a number of firms in British electrical engineering industry, disfavor for electrical investments —indeed it was one of the severe blows that our electrical industry sustained a few years ago and has not recovered from yet. The company came to such a pass that the customers who were colliery and works owners dependent upon it for the supply of energy necessary for preventing an interruption of their industrial operations, had to step in and take the helm. The company, as has been recorded in these pages, has since passed through various other stages in which several smaller subsidiary companies have been formed to operate certain of the stations and supply energy in their neighborhood. Before the crash came, however, the company did excellent educational work among many of the mines, and there was promise of a most satisfactory development straightaway. Whether the course of colliery electrification in South Wales was greatly interfered with by reason of the Power Company's tribulations is one of those matters upon which a pretty safe guess might be made. However, things are now undoubtedly going ahead well, and nothing appears likely to stay the progress that has well begun. Three interesting undertakings, each of which has had its own electric generating station put down, may be mentioned in this article, namely: (1) The Aberdare collieries of the Powell-Duffryn Company; (2) the Cambrian collieries, in Clydach Vale; (3) the Ferndale collieries—the most recently completed system of the three.



FERNDALE COLLIERIES—POWER STATION ENGINE ROOM

THE ABERDARE COLLIERIES.

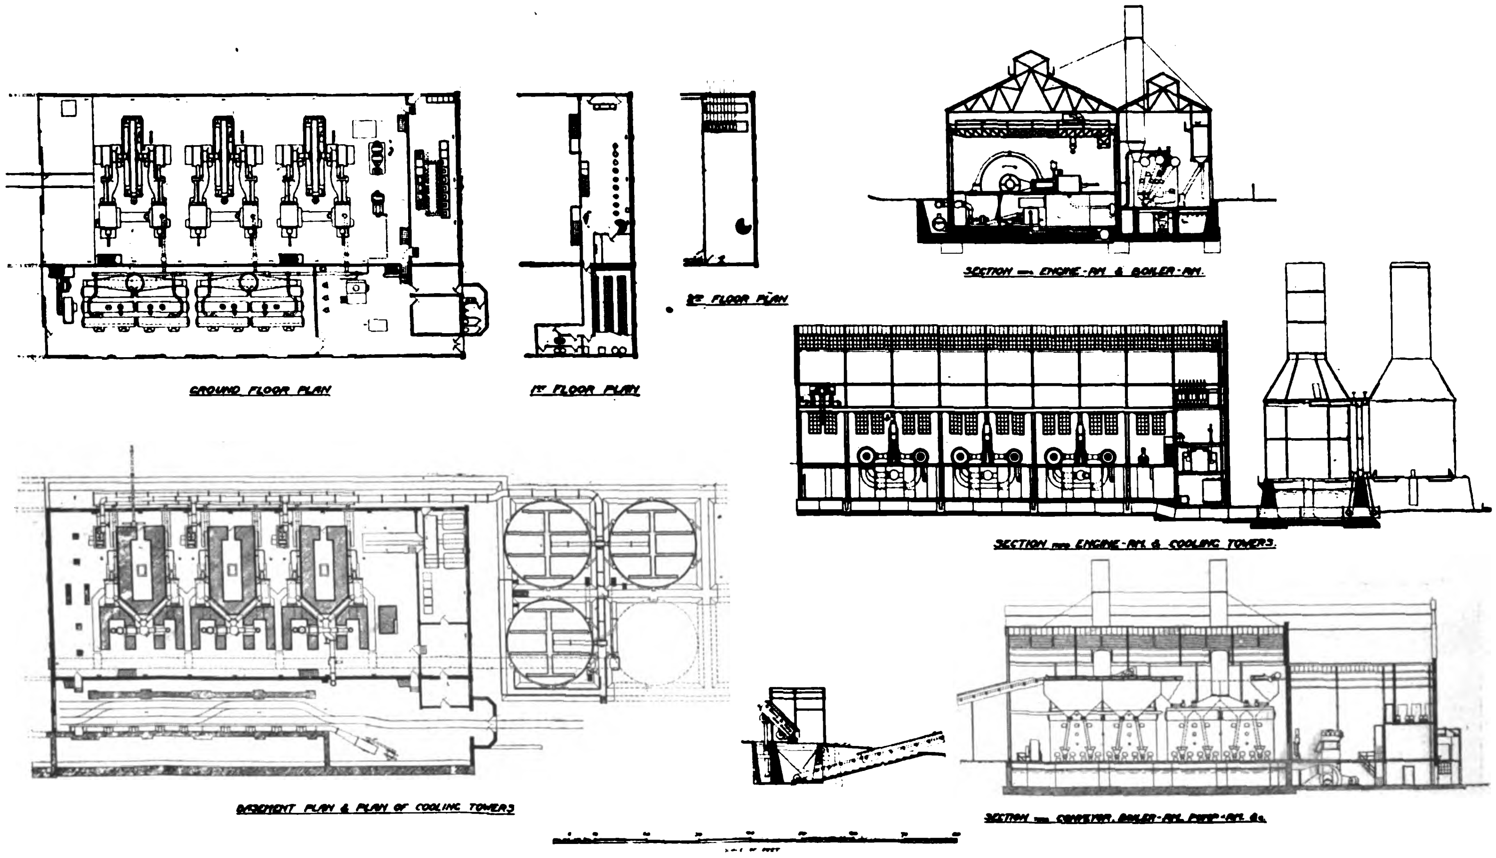
The equipment of the Aberdare collieries was put down to the designs of Charles P. Sparks, who acted as consulting engineer. He was responsible for the rearrangement of the electrical system under which a number of the pits had worked for several years, and for a great extension scheme. The Aberdare collieries, which are about twenty miles northwest of Cardiff, raise about half the annual output of the Powell-Duffryn Company, which was, a year or two ago, close upon three million tons. Six out of the nine pits were worked by isolated direct-current plants (200 and 400 volts), but these small plants gave way in the development scheme to one large power station for serving the entire pits in the valley, 3,000-volt, fifty-cycle, three-phase current being generated, and overhead transmission lines being employed. When this new power station commenced operations some three years ago 4,600 horsepower of motors were at work out of a total of 6,000 horsepower. The power-station plant comprised a number of 2,000 and 1,000 kilovolt-ampere, three-phase alternators, supplied by the Electrical Company, Limited (A. E. G.), each driven by Yates & Thom horizontal cross-compound, jet condensing type steam engines, which were served from Babcock & Wilcox water-tube boilers. A very detailed account of the plant, transmission lines, sub-stations, and the various operations performed in the mines was given by Mr. Sparks in a paper that he read before the Institution of Electrical Engineers in London.. A number of main and tail haulage machines driven by 150-horsepower, 3,000-volt, 290 revolutions per minute, variable-speed motors; fans driven by 180-horsepower motors of the same speed and pressure; screens rope-driven from sixty-horsepower, 3,000-volt, enclosed motors (485 revolutions per minute); an aerial ropeway driven by fifteen-horsepower motor; three-throw ram-pumps; winding machine with 100-horsepower motor (depth of pit ninety yards), giving an output of seventy tons of coal per hour, also a winder in a staple pit, driven by an eighty-horsepower motor—these are some of the representative examples.

THE CAMBRIAN COLLIERIES.

The Cambrian collieries, which are in Clydach Vale, produce in three pits about 1,000,000 tons per annum. Steam working gave way to electrical operation for working haulages, pumps, coal-cutting machines, the supply being first obtained from the Power company to which reference is made above. C. P. Sparks, who was the consulting engineer in this case, also persuaded the authorities to put down their own power plant. This consists of three 1,000-kilovolt-ampere Siemens, three-phase, rotating field type alternators, generating a 2,200-volt, twenty-five-cycle current. These alternators are driven by Belliss steam engines, and the speed of the sets is 250 revolutions per minute. The boilers are thirty feet by nine feet, Lancashire type, with Sugden superheaters. A small steam-driven set and two seventy-kilowatt motor-generators supply direct current for auxiliary purposes. Step-down transformers (2,200 to 400 volts) are fitted at one end of the switchboard for giving the supply to the surface and auxiliary motors. Some twenty-one induction motors aggregating 1,890 horsepower and ranging from 220 horsepower to three horsepower serve for the principal operations. The greater part of the supply is taken into the mine at from 2,000 to 2,200 volts and is received by the motors at that pressure.

THE FERNDALE COLLIERIES.

By the courtesy of W. H. Patchell we are enabled to give in fuller detail the particulars and illustrations of the last completed of the three undertakings named, i. e., the Ferndale collieries installation, for which he was consulting engineer. Here again a special power station has been put down. This is situated at Tylorstown, and the building is constructed on a steel frame which sustains the whole weight of the roof and upper floors, the brickwork serving merely to clothe the skeleton. The reason why this type of building was adopted was the ever present possibility of subsidence at the surface of a colliery. The north end of the station is temporary, so as to admit of future extensions. The building is served by a twenty-five-ton overhead traveling crane having a sixty-seven-foot span.



PLAN AND SECTIONAL VIEW, POWER STATION, FERNDALE COLLIERIES

Four water-tube boilers of the Stirling three-drum type are installed, each having 6,209 square feet of heating surface. Each boiler is provided with two underfeed mechanical stokers and a superheater of the McPhail type with 800 square feet of heating surface, and is capable of evaporating 30,000 pounds of water per hour at a pressure of 180 pounds per square inch and imparting a superheat of 150 degrees Fahrenheit.

The stokers are worked by a system of forced draught, which is supplied by two Musgrave fans, each being belt-driven from a motor.

The boilers are arranged in two batteries, each battery being connected by a breeched piece to a steel chimney seven feet in diameter and seventy-five feet high.

The coal used is run into Messrs. D. Davis & Sons' private siding from the Taff Vale Railway, where the wagons are

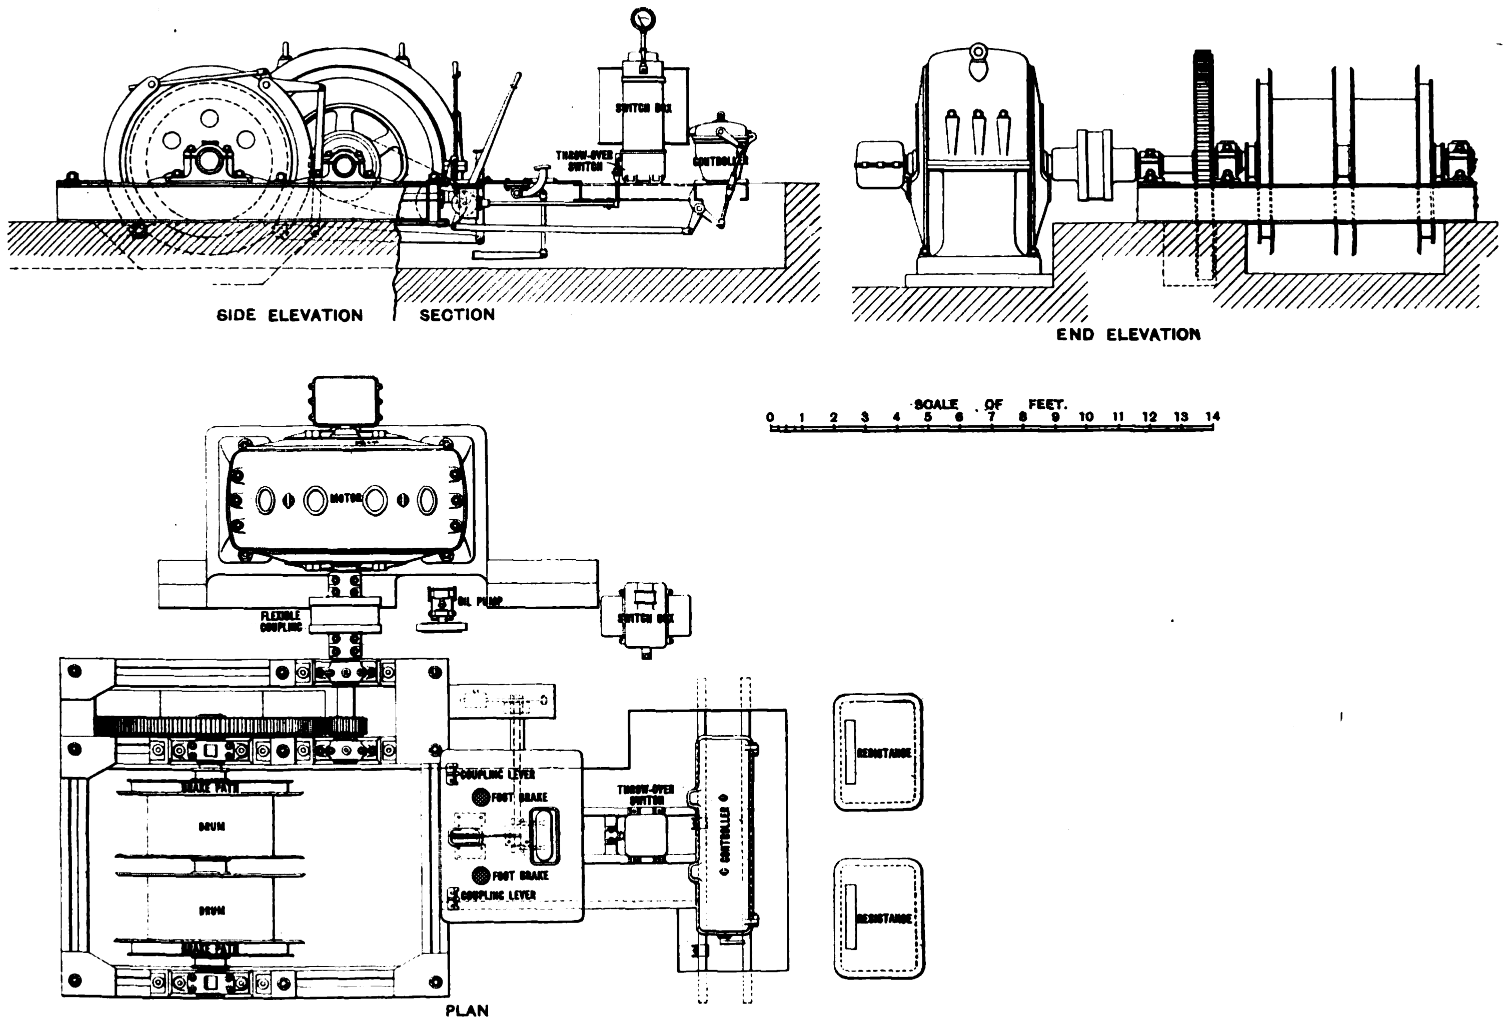
The ash from the stokers is removed by opening a sluice valve under the boilers, when the ash falls into narrow-gauge trucks in the boiler-room basement.

The water supply is pumped from Messrs. Davis's No. 8 pit, close by, and is stored in a large cast-iron tank outside the building. There is also storage in a large tank 100 feet long under the boilers.

The feed pumps, of which there are three, are of Messrs. Clarke, Chapman's make, tandem-compound, each capable of delivering 5,000 gallons of water per hour against the boiler pressure.

The exhaust steam from the pumps is

low-pressure, fifty-six inches; the stroke, fifty-five inches; speed, ninety-four revolutions per minute; working pressure, 170 pounds per square inch, with superheat of 150 degrees Fahrenheit at the stop valve. Each engine is supplied with two jet condensers and feed-water heaters. The injection water is taken from cooling tower concrete tanks through a main four feet in diameter buried in the engine basement floor, and after passing through the condensers is collected in a wrought-iron hot-well main. The circulating water is lifted to the cooling towers by centrifugal pumps connected to the hot-well



ARRANGEMENT OF THE 200-HORSEPOWER HAULAGE, FERNDALE COLLIERIES

tilted by hydraulic rams which are worked from the boiler feed pumps. The coal having been tilted into a hopper, it is then carried by a motor-driven inclined band conveyor into and along the boiler room, where by means of a throw-off carriage the coal is discharged into the bunkers above the boilers, which have a capacity of 150 tons, and is carried by chutes at the bottom of the bunkers to the stoker hoppers. The conveyor carries twenty tons of coal per hour and runs almost noiselessly.

taken to a Cochrane open-type exhaust steam heater, where it heats the feed water on the suction side of the pumps.

For use in emergency there is provided a Worthington tank pump, which draws from the river in the unlikely event of water from the mine failing.

The three main steam engines are of the cross-compound type made by Messrs. Sulzer Brothers, each capable of giving 2,500 horsepower at normal load. The dimensions of the cylinders are, high-pressure, thirty-three and one-half inches;

There are three natural draught wrought-iron cooling towers thirty-three feet in diameter and eighty-three feet high. The circulating water enters about thirty feet from base and is discharged into wooden troughs, which equally divide the water on cross timbers beneath, and so break it up into a fine rain; after cooling the water is collected in the concrete tanks under the towers.

The three-phase generators, coupled direct to Sulzer engines, are of the revolving-field, flywheel type, each having a normal continuous output of 1,600 kilowatts at a power factor of 0.85 and a potential of 2,200 volts, and having an overload capacity of twenty per cent for two hours, or thirty per cent for half an hour. The guaranteed temperature rise is not to exceed forty-five degrees centigrade after ten hours' full load run as measured by thermometer. These generators are of the Lahmeyer Electrical Company's make.

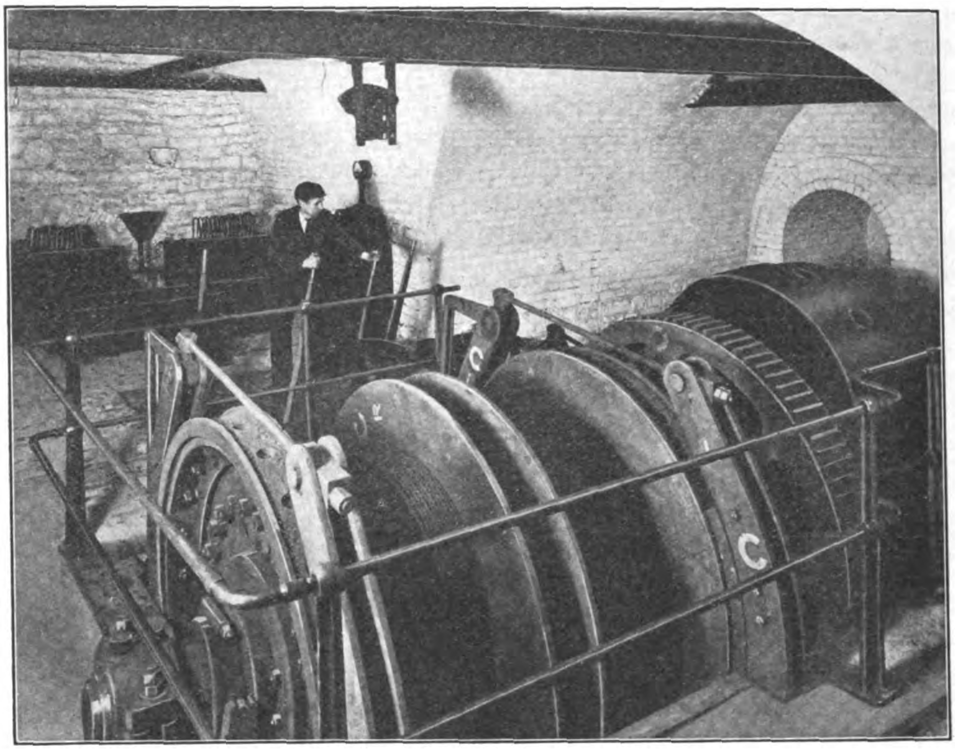
The total weight of each generator is 107 tons; of the revolving field, approximately seventy-five tons. The generators are separately excited at 200 volts from a seventy-five kilowatt Bellis-Lahmeyer exciter running at a speed of 525 revolutions per minute.

As a spare to the Bellis exciter there is a 100-120-kilowatt motor-generator booster set, consisting of a 180-horsepower, 2,200-volt, three-phase motor, coupled to a shunt-wound, 120-kilowatt generator. The booster is mounted at the end of the shaft and is capable of raising the voltage from 200 to 290 volts to charge the Tudor battery; the latter has a capacity of 380 ampere-hours when discharging at a thirty-eight-ampere rate and consists of 115 cells. The regulation is done by hand by a twenty-one-contact regulating switch. The battery can also be charged by the Bellis set, the generator of which is arranged so that its voltage can be increased to 290 volts in order to allow of its acting as a spare in case of a breakdown in the motor-generator set.

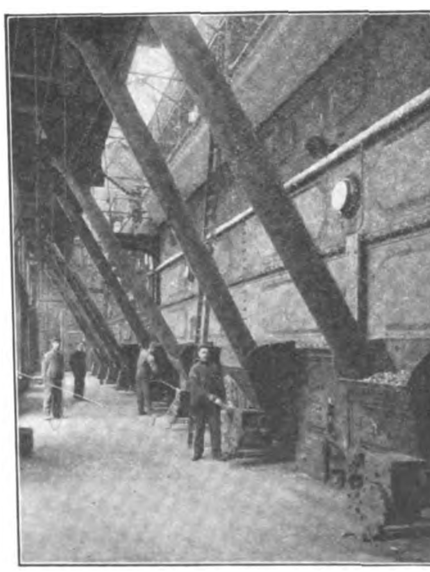
The electric current is taken from the generators to the main switchboard, which is situated at the south end of the building and is of the most modern type. The operating platform is occupied by a series of desks from which the main generators are controlled and switch pillars controlling the feeders. These desks and pillars merely carry switch-handles and low-tension instruments. The actual switches themselves are enclosed in a lower story. This has the advantage of giving ample room for the disposition of the high-tension gear in a chamber which need only be visited for the purposes of inspection and leaves the switchboard operators free to attend to their duties on the platform, which is claimed to be even safer than a switchboard of an ordinary low-tension station. These switches have been provided with Ferranti time-limit relays.

The current is taken from the power station by main feeders to distributing centers at the various pits. The motors are generally worked at 2,200 volts, but in certain places, in accordance with the Home Office rules, the current has to be stepped down by transformers to 400 volts.

Nos. 6 and 7 pits are only about 900 yards from the power station; the current, therefore, is taken direct to them at 2,200 volts. In the case of Nos. 1 and 5 pits, at Ferndale, which are 2,500 yards away, and Nos. 2 and 4 pits, which are some 2,000 yards further up the valley, the current is stepped up to 6,600 volts and transmitted by bare overhead wires which are run on duplicate poles. Step-down transformers are fixed at sub-stations convenient to the pits, where the pressure is again reduced to 2,200 volts, or 440 volts, as required.



200-HORSEPOWER HAULAGE IN NO. 1 PIT OF THE FERNDALE COLLIERIES



BOILER HOUSE IN POWER STATION OF FERNDALE COLLIERIES

Some twenty-two haulages are being installed, varying in size from 200 horsepower to fifty horsepower. The gears were made specially heavy, to Mr. Patchell's specification, by the Uskside Engineering Company. Slow-speed motors have generally been adopted and the electrical equipment is of massive construction supplied by the Lahmeyer Company. The controllers are of a new design arranged by the consulting engineer.

The haulages are generally of main and tail type and work at a speed of six miles an hour. They are principally of single reduction, but in some cases to suit the exigencies of the positions in which they had to be installed, double reduction type has been chosen. In all cases there is a flexible coupling between the motor and the gearing which to a very large extent takes the jar of the gear off the motor. These electrically driven gears are very popular with the drivers; and, owing to their reliability and ease of working, not only have great economies been effected over the old steam-driven haulage gears, but it has also been possible to obtain a greatly increased output, as there are no delays in starting up, the haulage gear commencing work immediately the driver manipulates the lever.

The underground pumping is now being handled electrically; in some cases by three-throw pumps made by the Uskside Company, and in other cases by high-lift Sulzer centrifugal pumps.

VENTILATION.

Ventilation is a most important part of the work, not only from the colliery manager's point of view, but also inasmuch as the continuous user makes it a most desirable load for the power station. At the new pit a "Sirocco" fan has been put down to handle 300,000 cubic feet of air per minute at a four-inch water gauge. This fan is driven electrically from either end of its shaft by two Lahmeyer motors working at 2,200 volts. One of the "Schiele" fans, which has been driven for several years by a steam engine and supplying 300,000 cubic feet of air per minute at 3.5-inch water gauge, has lately been converted to an electrical drive. Two other "Sirocco" fans are at present being installed.

The new pit is being entirely equipped with electrical machinery, including a winder, which is being manufactured by the Lahmeyer Electrical Company. It will work on what is known as the "Ilgner" system and is constructed to raise 1,800 tons of coal a day.

The consulting engineer, W. H. Patchell, of Caxton House, Westminster, has for many years been largely identified with the introduction of electricity for mines and was the electrical member of the Home Office Departmental Committee of Great Britain for the drafting of suitable rules for the use of electricity in mines. He has collaborated throughout with David Hannah, manager to the Ferndale collieries.

We understand that what is claimed to be the first large electric winding engine erected in the United Kingdom has just been put down at the Maritime pit of the Great Western Colliery, Pontypridd. In this case G. J. Hooghwinkel is consulting engineer.

Telephone Company Demands Portion of Telegraph Tolls.

The Cumberland Telephone Company has made a demand on the Western Union and Postal Telegraph companies, at New Orleans, for fifteen per cent of the tolls of messages which they transmit over the telephone instead of by messenger. The telegraph companies assert their right to use the telephones for any legitimate purpose, and refuse to pay the commission demanded, which makes it likely that they will order their instruments removed, for this was done under similar conditions in Chattanooga.

FINANCIAL REPORTS OF ELECTRICAL COMPANIES.

MONTGOMERY LIGHT AND POWER.

The Montgomery (Ala.) Light and Power Company's report for the year ended June 30, 1908, is as follows: Gross, $320,375; expenses, $151,508; net, $168,867; interest, $103,194; surplus, $65,673; reconstruction reserve, $12,000; net profits, $53,673; equal to 2.6 per cent earned on the $2,000,000 capital stock. The net profits for the preceding year were $48,983.

PORTO RICO RAILWAYS.

The report of the Porto Rico Railways Company for the month of September and nine months ended September 30 shows as follows: September gross, $34,082; expenses, $19,649; September net, $14,433; nine months' gross, $277,233; expenses, $159,278; nine months' net, $117,955, as compared with $107,142 for the preceding year, an increase of $10,813.

TWIN CITY RAPID TRANSIT.

The report of the Twin City Rapid Transit Company for the month of September and nine months ended September 30 is as follows: September gross, $583,876; expenses, $276,588; September net, $307,288; charges, taxes and preferred dividends, $138,667; September surplus, $168,621; nine months' gross, $4,765,801; expenses, $2,372,024; nine months' net, $2,393,776; charges, taxes and preferred dividends, $1,145,122; nine months' surplus, $1,248,654, as compared with $1,323,094 for the same period of 1907.

DETROIT UNITED EARNINGS.

The report of the Detroit United Railway Company for the month of September and nine months ended September 30 shows as follows: September gross, $668,489; expenses and taxes, $423,136; net, $245,353; other income, $5,028; total income, $250,381; charges, $135,049; surplus, $115,332, comparing with $114,478 for September, 1907. January 1 to September 30: Gross, $5,324,855; expenses and taxes, $3,395,252; net, $1,929,603; other income, $45,055; total income, $1,974,658; charges, $1,218,860; surplus, $755,798, comparing with $888,241 for the corresponding period of last year.

LITTLE ROCK RAILWAY AND ELECTRIC.

Little Rock Railway and Electric's earnings for September and nine months ended September 30 are as follows: September gross, $54,655; expenses and taxes, $27,340; September net, $27,315; charges and sinking fund, $10,605; balance, $16,710; other deductions, $3,000; September surplus, $13,710, comparing with $21,592 for 1907. Nine months' gross, $495,817; expenses and taxes, $254,909; nine months' net, $240,908; charges and sinking fund, $90,796; balance, $150,112; reserve funds, $27,000; nine months' surplus, $123,112, which compares with $147,753 for the corresponding nine months of 1907.

TOLEDO RAILWAYS AND LIGHT.

The report of the Toledo Railways and Light Company for the month of September and nine months ended September 30 is as follows: Month of September: Gross, $222,891; expenses and taxes, $111,899; net, $110,992; other income, $61; total income, $111,053; charges, $71,976; surplus, $39,077. January 1 to September 30: Gross, $1,864,822; expenses and taxes, $1,019,823; net $844,999; other income, $3,072; total income, $848,071; charges, $635,743; surplus, $212,328. This is a decrease of $7,176 from the surplus for the corresponding months of the preceding year.

MEMPHIS STREET RAILWAY.

Memphis Street Railway's report for September and nine months ended September 30 is as follows: September gross, $143,044; expenses and taxes, $88,971; September net, $54,073; interest charges, $35,532; balance, $18,541; reserve fund, $2,500; September surplus, $16,041, compared with $20,304 for September, 1907. Nine months' gross, $1,199,765; expenses and taxes, $760,319; nine months' net, $439,446; interest charges, $314,970; balance, $124,476; reserve fund, $22,500; nine months' surplus, $101,976, as against $136,037 for the preceding year.

BIRMINGHAM RAILWAY AND LIGHT.

The Birmingham (Ala.) Railway, Light and Power Company's report for September and nine months is as follows: September gross, $177,891; expenses and taxes, $122,266; September net, $55,625; charges and sinking fund, $43,617; September surplus, $12,008, as against $29,363 in 1907. Nine months' gross, $1,586,026; expenses and taxes, $1,037,924; nine months' net, $548,102; charges and sinking fund, $394,772; nine months' surplus, $153,330, as against $190,013 for the corresponding quarters of 1907.

TWO-MOTOR-DRIVE WEB PRINTING PRESS, MANUAL CONTROL.

BY S. H. SHARPSTEEN.

A diversity of opinion exists among newspaper people as to which is the better, manual or automatic motor control. This is due in part to there being no data compiled to which the printer can refer and get the information that will enable him to review clearly all the questions involved.

The man in charge of the apparatus that drives the presses to print one of the large New York city dailies, when asked why he did not install automatic or push-button control on a web press, recently purchased, said, that he had just about press capacity sufficient to produce the editions in the allotted time, and that he was compelled to use apparatus with the least complication to permit of easy inspection.

In another press room of a metropolitan daily, where there is a recent installation of newspaper web presses, the electrician stated that the coils in the automatic devices sometimes burned out. On asking him what was done if a solenoid coil failed while a press was producing, he replied that in such an emergency the press was shut down until a coil could be taken from the control panel of an extra press equipment. The coil could be changed from one panel to another more quickly than the plates could be transferred from press to press.

It is now pretty generally understood in the newspaper world that where automatic or push-button control is used in the press room of a large daily, an extra press and electrical equipment is necessary to allow repairs when the control of an equipment goes out of commission. As a precaution an extra press would probably be installed regardless of the control in a new, large newspaper plant.

The business manager of a New York daily investigated web-press drive and control during eighteen months or more. Newspapers throughout the United States that were using electrical drive and control were consulted and the data thus received were carefully arranged by an electrical engineer. Manual control was chosen and installed; one man at the controller is responsible for the movement of the press. The only remote control used in this installation is the emergency stop, push-buttons being placed in positions of easy access about the press, to be used in case it is desired to stop the press quickly.

The men in a press room are often placed under a mental strain that tends to cause them to do foolish things. As an example: After the stock exchange closes there is a rush from the time the last news comes into the office of an evening publication, until the papers are being delivered. The newsboys are anxious to be first on the street with the Wall Street editions, and the delivery men have trains that should be met. As the last plates are securely fastened and the familiar roar of the presses goes out, there is a general stir among the people who take the papers. The business manager, possibly in a distant office, has been anxiously looking at the indicators, and as the presses are going on time he settles back in his chair with a contented expression on his face. Now let something happen in the press room that cuts short the product about the time the papers commence to pass out, and excitement seizes every man about the place. A short holdup is not important, but long delays at such time are serious, and each pressman is usually very eager to hurry things all he can to get the press running. With control stations located about the press room and possibly on a floor below, men will sometimes push the wrong button or one man pushes a button causing the press to do one thing, and another man at some other station pushes a button to perform a different movement, and serious trouble may follow. Much time and money have been spent to make automatic control devices interlocking to prevent trouble of this kind, but it seems impossible. With automatic control the service switch, through which current passes for all the devices of an equipment, is located, as a rule, on the controller panel in some remote place near a wall to which the panel can be fastened, and which also makes a fireproof back for the resistances. If the complicated devices for quick shutdown operated by a small switch or push-button and many feet of small wire gets out of working condition and some trouble with the press requires a quick stop, the pressman must hunt, possibly, on a long row of panel boards among many switches, for the one that will cut the equipment in distress from the line. If the motor did not respond to the emergency button, the slowdown and stop button would bring the equipment to rest, but might be too slow to save serious trouble. A second or duplicate quick-stop device could be installed to make an emergency stop more sure. In some cases a dynamic brake is used on large press equipments, in connection with an emergency stop, and these should be tried every day, while the press is out of use, to see if they are in good working condition. When a large web press is running at a high speed and is stopped quickly by the use of a dynamic brake there is excessive strain on press and motor, in many cases pitting the commutator; hence, the tests are seldom made, and defects not properly looked after.

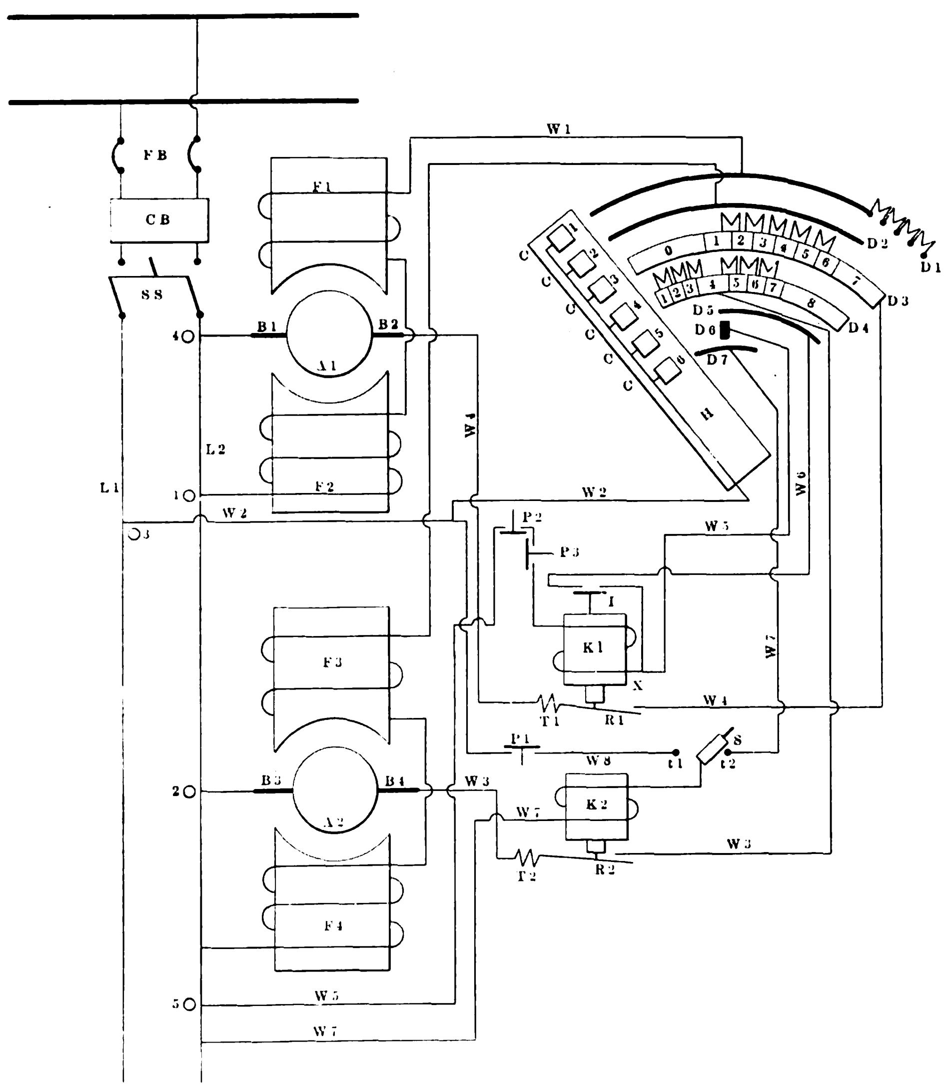
There is another side of this question. The home of a newspaper is of interest to the masses who read the paper. An imposing building, properly equipped inside, is important; a number of modern presses controlled as if by magic is no small factor in swaying the mind of the public.

Important dailies that have automatic control keep a good electrician constantly in attendance, especially when the presses are running. This is a reflection on the electrical industry. The proper electrical apparatus, when well installed, to drive a web printing press, should not demand as much attention to keep it going as a train of cars in the subway. The idea of having an electrician constantly on duty when a web press or presses are running is as unnecessary as it would be to have a high-priced electrician on every subway train. When running pastes are made on the floor below the press room and presses, it is convenient to have a press-control station near the paper supports, to enable an employe that is looking at the paste as it is made, to operate the press in a proper manner. In many cases the manual control could be located to allow the operator to see, through a hole in the floor, the pasting being done. A few signal lamps, a speaking tube, or a similar device, could be used.

The diagram herewith illustrates a simple form of two-motor drive and manual dial-type controller, F B being two cartridge fuses, one in each side of the circuit. If the ordinary bare fuses are used they should be enclosed in a fireproof box.

A web-press equipment should contain a substantial double-pole knife switch provided with a make-and-break device that will prevent arcing at the blades and jaws, especially if it opens and closes the field or fields of the motor or motors. The service switch S S ought not to be left to a contractor to buy in the market what is called standard goods. It should be a first-class article of a type that has proven by long and hard usage that it will stand printing-press work without requiring special attention. In many cases a switch of a certain amperage has been specified, the contractor selecting, from a catalogue, the cheapest one of the required capacity, that the fire underwriters will pass. With an ordinary stationary motor that is stopped and started but twice each day this switch might answer, but in web-press work, with manual control the switch is opened and closed many times each day, and constant use causes the pressman to handle it roughly. This switch ought to be placed on a substantial support near the controller, to enable the pressman operating the press to open it quickly in case of trouble that puts out of commission the other press-stopping devices, and since both polarities of the circuit come close together at the jaws and blades of the switch, it should be located between two slate or marble pieces to prevent wrenches or other tools being carelessly put across it, causing a bad burn. It is a familiar sight to see a careless employe use the hand that contains a wrench or oil can to open a switch on a printing press. In a rush a pressman might unintentionally do the same, causing a short-circuit, burning his arm or hand, and damaging a switch jaw or blade, making a delay in getting off an edition. These switches are sometimes placed in a small fireproof box and provided with lock and key to prevent the circuit being closed by some careless person when the pressmen are away.

When a web press is to be driven by an electric motor, if the current is to be taken from a large generator or from street service, it is well to understand that large quantities of electricity are ready to rush in and cause the motor to develop double its normal power or torque, or make a bad flash and burn if the insulation fails. It takes time for a fuse to blow, and since electricity is so quick, and there is such a large quantity to come, the sure way to protect a motor installation is by installing a double-pole circuit-breaker at C B, made by a responsible company, the breaker having a good record. In the press room of one of the Baltimore dailies a press, equipped with



TWO-MOTOR-DRIVE WEB PRINTING PRESS, MANUAL CONTROL.

motor drive, while standing still, the controller at the off position, was wrecked by the insulation breaking down between the frame of the motor and one of the series coils, allowing an excessive current to pass through the series winding and the armature with small or no resistance in circuit.

A good breaker, properly set, should have prevented the inrush of energy that stripped the press gears and put the equipment out of commission until new parts could be expressed from the press makers.

Consider that A 1 is the armature, F 1 and F 2 the field magnets of the main driving motor, A 2 the armature, and F 3 and F 4 the field magnets of the auxiliary motor for slow speeds.

When ready to move the press ahead, close the service switch S S on the line and the small switch S in the jaw J 2, and move the arm H slowly to the right. When brushes C 1 and C 2 touch on dials D 1 and D 2 the field magnets of both motors will be excited. The field circuit of the main motor connects with one side of the line L 2 at O 1 and is made up of field magnets F 2 and F 1, wire W 1, controller dial D 1, controller brush C 1 and wire W 2, which connects with the other side of the line L 1 at O 3. The field circuit of the small motor takes a similar course, but uses dial D 2 and controller brush C 2. Next, the small motor armature circuit closes in the controller as C 4 touches point 1 on dial D 4. Later, C 6 touches D 7, exciting contactor K 2, making the final close at R 2 in the armature circuit of the small motor, when it should turn slowly. The small armature circuit leaves line L 2 at O 2, and is formed of brush B 3, armature A 2, brush B 4, wire W 3, magnetic blowout coil T 2, contactor make and break R 2, a second portion of wire W 3, dial and part of resistance D 4, controller brush C 4, then by means of wire W 2, it is connected to line L 1 at O 3. When C 4 passes onto point 4, dial D 4, the resistance will be out of circuit with armature A 2, and the small motor will run at maximum speed, the press and large motor at a very low speed.

When ready for press production, continue to move arm H to the right, when C 3 should make good contact with point 1, dial D 3, closing the armature circuit of A 1 in the controller before brush C 5 touches D 5 and D 6. The instant that wire W 5 is closed at C 5, and D 6, the contactor is excited and makes the final close in the circuit of armature A 1 at R 1, when the large motor will develop torque, and drive the press at an increased speed, letting the small motor run free. During the travel of the arm H to the right, resistance will be cut in circuit with armature A 2 and out of circuit with A 1, the result being that the press will come to production speed and when C 6 leaves D 7 contactor K 2 will open at R 2; current will cease to pass through armature A 2, which, being connected to the press shaft or large motor shaft by a ratchet drive, will come to rest. The large motor armature circuit leaves line L 2 at O 4, passes through brush B 1, armature A 1, brush B 2, wire W 4, magnetic blowout coil T 1, contactor make and break at R 1, a second section of W 4, dial and resistance D 3, controller brush C 3 and wire W 2 to line L 1 at O 3.

The contactor is a type of automatic switch, which can be employed in a web printing-press equipment to advantage, especially where hand control is used.

If properly constructed and provided with magnetic blowout T 1, it will make and break the main current in a manner to prevent destructive arcing. It will provide a no-voltage release and can be operated by remote push-buttons to move the press slowly for make-ready and threading.

The exciting circuit W 5 of contactor K 1 leaves line L 2 at O 5, passes through push-button P 2 and P 3 coil of K 1, a second section of wire W 5 to D 6 and by means of C 5 and wire W 2 is connected with the line L 1 at O 3. This contactor provides a no-voltage release, and for this purpose is supplied with an auxiliary controller circuit leaving W 5 at X, and when the plunger is up in K 1, it passes through I, and by means of wire W 6 is connected with D 5.

As the controller arm H moves to the right, brush C 5 leaves D 6 before the motor comes to speed, and the arm is let rest, but the contactor K 1 is kept closed by its second controller circuit W 6. If the current should be cut off the line while running for production, the contactor K 1 would open both the main armature circuit at R 1 and the auxiliary contactor exciting circuit at I, as the plunger fell for want of excitation.

When the normal voltage of the system is returned, the main exciting circuit of K 1 will be open at D 6 and its auxiliary exciting circuit at I. Since no current can pass through the exciting coil it will not close the armature circuit of A 1 at R 1, and the arm H will have to be moved toward the left or off position until C 4 touches point 7, dial D 4, and C 6 touches D 7, starting the small motor, and later when C 5 touches D 6, the starting resistance of the large motor will again be in circuit to allow the large driver to commence furnishing torque under the proper conditions.

The press should be piped for four small wires and provided with outlets at convenient places for push-buttons. One circuit, placed in this pipe and supplied with push-buttons P 2 and P 3, and looped into the coil winding of K 1, will allow the exciting circuit of this contactor to be opened from convenient points by the pressman, and the press stopped while running for production. A second circuit, placed in the pipe and supplied with buttons like P 1, and looped into the coil circuit of K 2, will provide remote control for slowly moving the press.

During repairing or threading paper the press can be moved without a man stationed at the controller H. When the switch S is closed on jaw J 1, the contactor K 2 can be excited, independently of the controller arm, by the use of the button P 1 and the auxiliary circuit W 8, leaving W 7 at the switch S and passing to line L 1 by way of W 2 without going through D 7. When this remote control is desired, the controller arm is moved to the right until C 4 rests on point 1 or 2 of dial D 4 and S is closed on J 1; then, when the open-circuit push-button P 1 is held down, the exciting coil of K 2 is closed across the line, causing R 2 to close and pass current to start the small motor on a portion of its armature resistance.

When the plunger in K 1 falls and opens the armature circuit of the large motor at R 1 it could be made to close part of a dynamic or other brake device. If a dynamic brake were used, it would not be allowable to have this plunger, when it moved down, make the final close in the dynamic or brake circuit across the armature terminals of A 1. It would be necessary to add an automatic brake switch, controlled by push-buttons, about the press, to be used to make the final close in the dynamic-brake circuit. This plan allows the stop-button to be pushed and the press stopped by simply cutting off the current and letting the press come to rest without using a brake. If a very quick stop is needed, after the button for cutting off the current is pushed, the brake-button, if held down, will apply the brake. An automatic switch for this purpose will have to be of a type that will open when the push-button is released.

Water-Power Development at Great Falls, Mont.

Plans are being perfected by Chas. T. Main, engineer, Boston, Mass., for the immediate development of two powers near Great Falls, Mont.

The upper development is to be made at the falls known as Coulter's, Crooked and Rainbow, situated about three miles down the river from Great Falls. At this point the head will be about 105 feet high. A crib dam about twenty-five feet high will be built with masonry head gate, and waste-gate structures. A steel penstock twenty-two feet in diameter and about 2,500 feet long will extend from the intake to the power house. The latter will be of masonry construction, containing about 30,000 horsepower of wheels and electrical apparatus.

The lower development is about twelve miles below Great Falls. Here the fall is about the same as at the upper development. The dam will be of the same construction as at Rainbow Falls, the canal being 500 feet long, and directly below this, the power house. The equipment will be a duplicate of that at the upper development.

The engineering corps, already organized by Mr. Main, is now busily engaged in making surveys and in the preparation of plans. The work on the coffer dams is already begun, and it is expected to push the work of development to completion as fast as possible.

A considerable portion of the power developed will be used at the Boston & Montana Smelter, at Great Falls, Mont. The balance will be transmitted to more distant places.

Engineers' Society of Milwaukee.

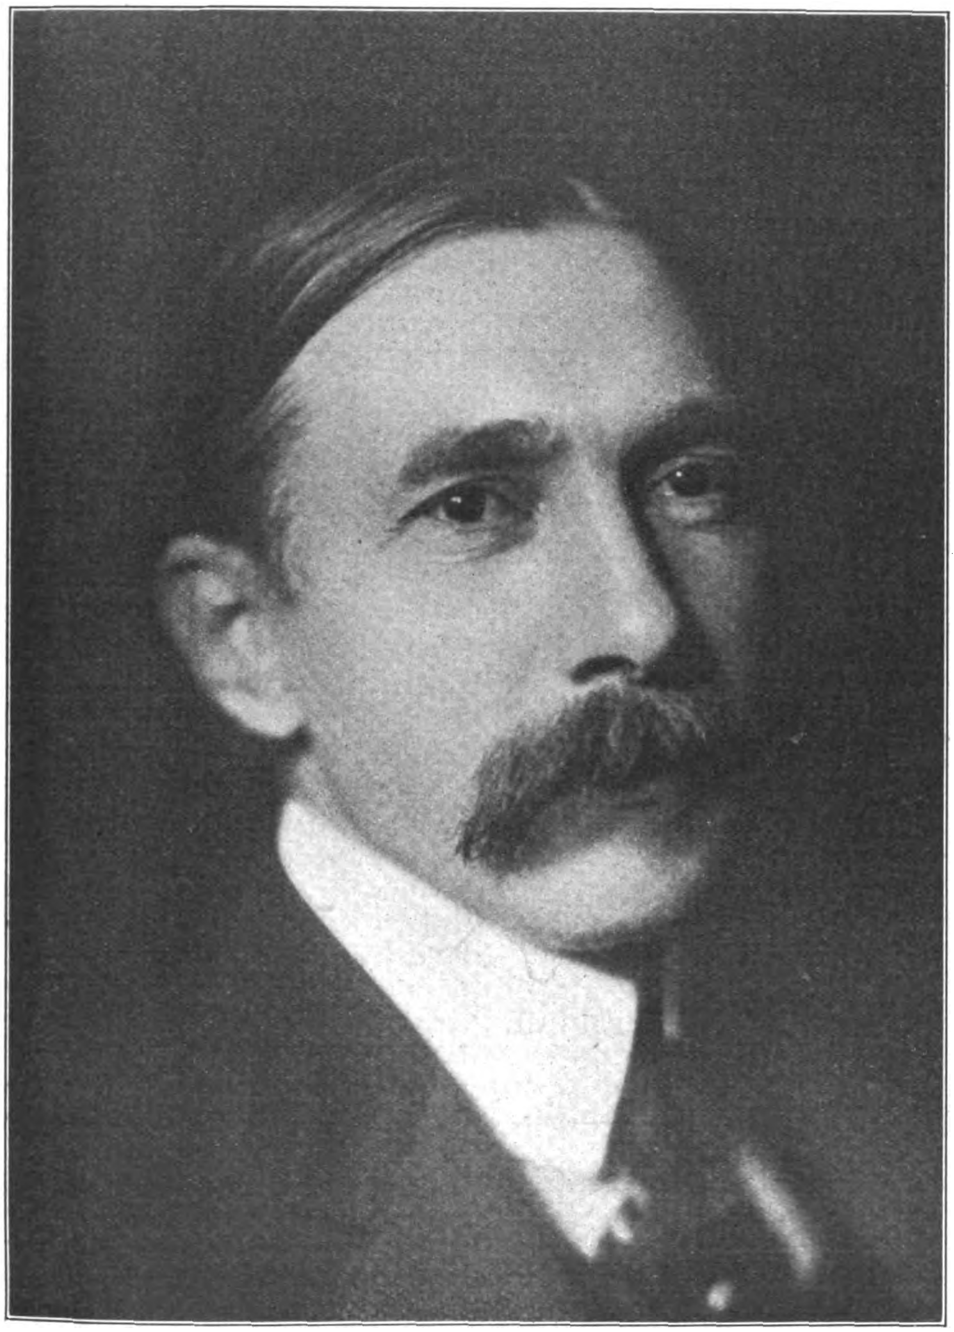
At the next monthly meeting of the Milwaukee Society of Engineers, which will be held on Wednesday evening, November 11, at the Builders' Club, 456 Broadway, Milwaukee, Wis., E. M. Griffith, state forester, will deliver an illustrated lecture upon "The Close Relation between the Forest Reserves and the Water Powers of Wisconsin." Besides discussing the general subjects of forestry and reforestation in their national and state aspects, the lecture will treat especially of the influence of forests in the regulation of stream flow, storage reservoirs, and waterpowers of Wisconsin. Invitations for the lecture may be obtained upon application to the secretary, W. Fay Martin, 456 Broadway, Milwaukee.

FREDERICK A. C. PERRINE.

BY RAY D. LILLIBRIDGE.

The death of Frederick A. C. Perrine, on October the twentieth at his home in Plainfield, N. J., after a protracted illness, has cut short one of the most promising careers in the engineering world, and one which is surpassed by few in actual accomplishment.

Dr. Perrine was of the highest type of young American engineer and man of affairs, and was a leader among the talented, earnest and well-trained men who have built up the standing of this country in applied science. He was born at Manalapan, N. J., in 1862, and received his education in that state, graduating from Princeton College in 1883, and receiving there subsequently the degrees of D. Sc. and A. M. A bent toward practical electricity resulted in his occupying positions of increasing responsibility in that field of engineering, then in the first stages of the wonderful expansion that it has undergone during the last three decades and to which Dr. Perrine contributed in an eminent degree. His distinguished career is, indeed, closely identified with the history of electrical engineering in this country. His work as chief engineer of the first great long-distance electric transmission line in this country—that of the Standard Electric Company of California—attracted attention the world over, and in recognition of this work he was awarded a gold medal by the Paris Exposition in 1900.



DR. FREDERICK A. C. PERRINE.

In addition to labors in important executive positions, like the presidency of the Stanley Electric Manufacturing Company, of Pittsfield, Mass., which he held from 1900 to 1905, he gave much of his best strength to a number of scientific and engineering societies, of which he was a member and for which he wrote many papers. He also devoted himself to technical editorial work, and to education—to the latter notably as professor of electrical engineering at Leland Stanford, Jr., University, from 1893 to 1900. He was also the author of a standard work on "Conductors for Electrical Distribution." For the last three years he had been devoting himself to consulting engineering, with offices in New York city.

Some of the societies of which Dr. Perrine was a member are the American Institute of Electrical Engineers, the American Society of Mechanical Engineers and the Institution of Electrical Engineers, of England. He was also a member of the Lawyers' and Engineers' clubs of New York city. In 1892 Dr. Perrine married Margaret Roebling, daughter of Ferdinand W. Roebling of Trenton, N. J., who, with their three children, survives him.

Pennsylvania Terminal Electrification Contract Let to Westinghouse Company.

Plans for the electrification of the Pennsylvania Railroad terminals in New York city have been announced with the signing of a $5,000,000 contract for the work with the Westinghouse Electric and Manufacturing Company. This action followed a meeting of the Pennsylvania directory in Philadelphia.

The contract is for the electrification of the entire Pennsylvania system from Harrison, N. J., to Jamaica, L. I. While the initial amount of apparatus will aggregate $5,000,000, this is said by no means to represent the full amount.

The Westinghouse company installed the 11,000-volt, twenty-five-cycle, single-phase system of the New York, New Haven & Hartford Railroad Company from Woodlawn, twelve miles from the Grand Central Station, to Stamford, Ct., and the award of the Pennsylvania contract to this company is to be taken as evidence that a similar double-catenary, single-phase trolley system will be used in the New Jersey, New York & Long Island electrification.

ALTERNATING CURRENTS AND THEIR APPLICATIONS.

BY EDSON R. WOLCOTT.

CHAPTER I. — (PART VI.) GENERAL PRINCIPLES. GRAPHICAL REPRESENTATION.

COMBINATION OF OHMIC RESISTANCE AND REACTION.

The ordinary or ohmic resistance of any of the coils just named cannot be added directly to the reactance to obtain the total opposition to the flow of current. The two can only be added as two forces are added that are acting on the same body at right angles to each other, as shown in Fig. 14.

Consider a body at A acted upon by two forces represented both in magnitude and direction by the lines A B and A D. The resultant, according to the parallelogram of forces, is represented both in magnitude and direction by the diagonal A C. Or, by geometry, the resultant A C can be expressed as follows:

$$AC = \sqrt{AB^2 + AD^2}$$

EXPRESSION FOR IMPEDANCE.

In a similar way the total opposition to the flow of an alternating current, that is, the impedance can be represented as the square root of the sum of the squares of the resistance and the reactance, thus:

$$Z = \sqrt{R^2 + X^2}$$

where Z represents the impedance, R the resistance and X the reactance; but since

$$X = 2\pi f L$$

on substituting,

$$Z = \sqrt{R^2 + (2\pi f L)^2}$$

or the current in such a circuit would equal

$$I = \frac{E}{\sqrt{R^2 + (2\pi f L)^2}}$$

It will be noticed from this expression that when L is zero the term $2\pi f L$ disappears and

$$I = \frac{E}{R}$$

which is the expression for the current in a direct-current circuit or in an alternating-current circuit when there is no inductance.

COMPONENTS OF ELECTRIC FORCE.

From the expression above it is evident that electromotive force E can be considered as made up of two components, thus:

$$E = I\sqrt{R^2 + (2\pi f L)^2}$$

or

$$E = \sqrt{R^2 I^2 + (2\pi f L)^2 I^2}$$

Note.—This serial was begun in the Western Electrician of October 3, 1908.

where R I is the ohmic potential drop and $(2\pi f L)$ I is the inductive drop. These two quantities can be represented graphically as two potential differences acting at right angles to each other just as the two forces were represented in Fig. 14. For example, in Fig. 15, let A C represent the ohmic drop I R, and B C represent the inductive drop $2\pi f L I$, then the line A B will represent E. As a concrete example, suppose I R equal 100 volts and $2\pi f L I$ equal 50 volts, then E would equal

$$\sqrt{100^2 + 50^2} = \text{about 112 volts.}$$

Or the result can be obtained graphically from Fig. 15. If A C be drawn to represent 100 units and B C to represent 50 units, then A B will represent 112 units nearly.

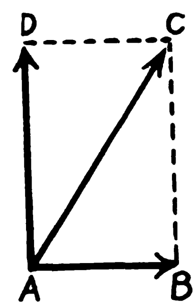


FIG. 14.—PARALLELOGRAM OF FORCES.

Suppose that under the above conditions a current of 10 amperes was flowing; then, since

$$I R = 100 \text{ volts},$$

R would equal 10 ohms, and since

$$2\pi f L I = 50 \text{ volts},$$

the reactance $2\pi f L$ would equal 5 ohms. If the frequency, f, is 60 cycles per second, then

$$L = \left[\frac{5}{2\pi 60}\right] = \left[\frac{5}{377.04}\right] = .0132 \text{ henry.}$$

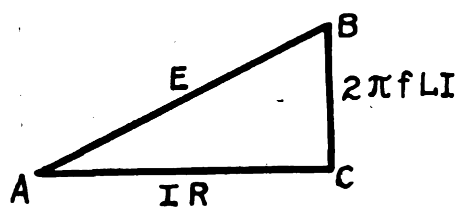

FIG. 15.—GRAPHIC REPRESENTATION OF ELECTROMOTIVE FORCES.

CALCULATION OF INDUCTANCE.

In other words, if an alternating current having an electromotive force of 112 volts and a frequency of 60 cycles per second be applied to a coil having a resistance of 10 ohms and an inductance of 0.0132 henry, a current of 10 amperes will flow.

It will be noticed that the inductance of a coil can be determined in a manner similar to the above calculation. On passing a direct current of 112 volts through the above coil a current of 11.2 amperes will be obtained, showing that the resistance R is equal to 10 ohms. With an alternating current, if the value of the current is 10 amperes, then the total expression is

$$I = \frac{E}{\sqrt{R^2 + (2\pi f L)^2}}$$

or

$$10 = \frac{112}{\sqrt{10^2 + (377\,L)^2}}$$

or

$$112^2 = 100 \quad 10^2 + (377\,L)^2$$

or

$$25.44 = (377\,L)^2$$

or

$$L = 0.0132 \text{ henry.}$$

It is to be understood that the above formula is used because it expresses the conditions that lead to a result corresponding to that obtained by experiment. It is similar in appearance to a formula expressing the resultant of two forces acting on the same body at right angles to each other, as already stated. Now the question arises as to how it is that the ohmic or non-inductive drop and the inductive drop can be considered as acting at right angles to each other?

CURVES OF COMPONENT ELECTROMOTIVE FORCES.

Suppose an alternating electromotive force is flowing through a straight conductor in the manner illustrated in Fig. 16 by the curve O B C D. There will then be no appreciable inductive effect. Let the straight conductor now be coiled and iron inserted in the coil, an induced electromotive force will appear in the coil itself, being that generated by the magnetic field when its energy reappears in the wire as an electric current as already explained. This induced electromotive force, as has been found by experiment, reaches a maximum when the current producing it is making its most sudden change, which is at the point when it is changing from a current in one direction to a current in the opposite direction.

The current curve is represented by the dotted line in Fig. 16. It passes through a zero value at the point C, and therefore this will be the point at which the induced electromotive force will reach a maximum, as shown on the curve M N P Q, which represents the curve of the induced electromotive force, or the inductive drop.

Let the curve O B C D represent the non-inductive drop or the electrical pressure that is forcing the current, represented by the dotted line, through the wire. The resultant of the inductive and the non-inductive drop is the electromotive force which must be applied to the coil to generate the current indicated by the dotted curve. It is found by adding the instantaneous values of the curves O B C D and M N P Q.

Subtracting the length 1-3 from the length 1-2, because they are in opposite directions, gives the point 1, which is on the O X axis, since the two are equal; likewise 4-5 added to 4-6 gives the point T, which is the maximum value of the new curve; 7-8 added to 7-8 gives the point W, and so on.

APPLIED ELECTROMOTIVE FORCE.

The curve 1 T S therefore represents the combined effects of O B C D and M N P Q, that is, the applied electromotive force, or, vice versa, if an electromotive force such as is represented by the curve 1 T S is applied to an inductive circuit such that the induced electromotive force is represented by the curve M N P Q, then, the active electromotive force will be represented by O B C D and the current by the dotted line.

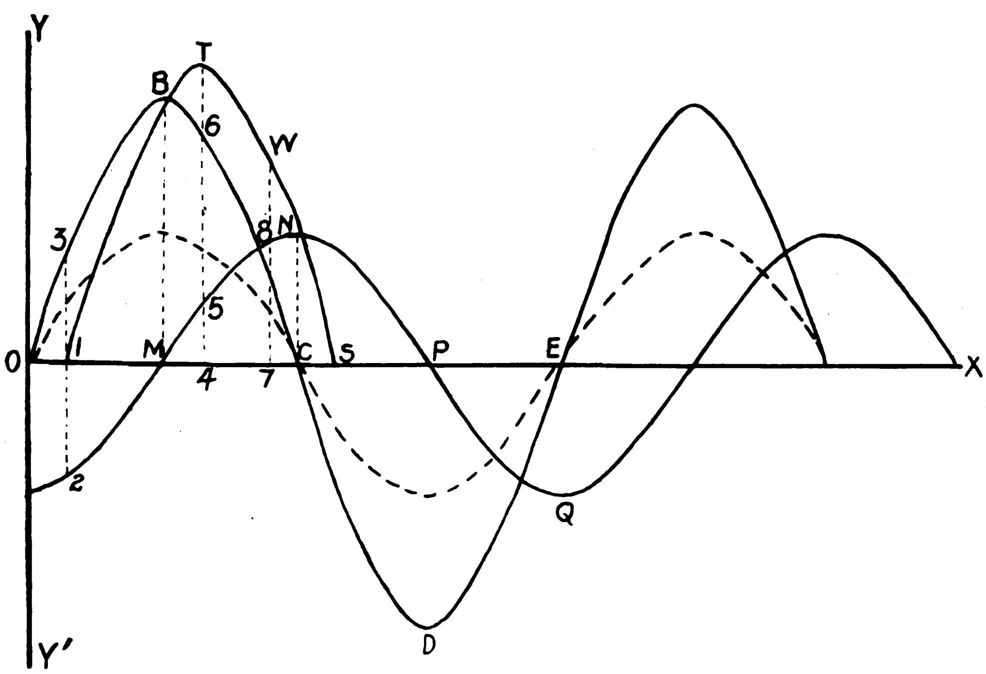

FIG. 16.—CURVES OF ELECTROMOTIVE FORCE AND CURRENT.

PHASE.

Three hundred and sixty degrees represent a complete cycle, so that the distance O E represents the time of a complete cycle, O C that of a half cycle, and O M or M C that of a quarter cycle, or 90°. The two electromotive forces O B C D and M N P Q reach a maximum one quarter of a cycle out of step with each other and are said to be 90° out of phase with each other. Representing the effective values of all of these curves by lines, a triangle similar to that of Fig. 15 is obtained. Since M N P Q is 90° out of phase with O B C D, the effective value of the latter will be represented by a line at right angles to that representing the former. It will be noticed that the applied electromotive force as represented by the curve 1 T S is out of phase with the current curve, which is represented by the dotted line. The distance 0 1 is about three-tenths of the distance O M, which represents a quarter cycle, or 90°. The two curves are therefore three-tenths of 90°, or 27 degrees out of phase with each other. The current and applied electromotive force are always out of phase in an inductive circuit.

There is a mechanical analogy to this: A pendulum may be oscillating to and fro and another oscillatory motion may be applied at right angles to the first, whereupon the pendulum will then execute a motion which is the resultant of the two.

[To be continued.]

Electricity Direct from Coal.

In a paper on "The Scientific Control of Fuel Consumption," read on September 29 before the Iron and Steel Institute, H. E. Armstrong, professor of chemistry in the City and Guilds of London Central Technical College, made some interesting observations concerning the direct conversion of the energy latent in fuel into electrical energy. He remarked that to say that this was impossible would be absurd; it was useless to exaggerate the difficulties. Hydrogen can be burned electrically in the Grove gas battery, but there is no economical process of preparing hydrogen; it can, however, be obtained by passing steam over red-hot coal, but only in admixture with carbonic oxide. "Why not burn such a mixture electrically?" it may be asked. Strange to say, not only are we unable to substitute carbonic oxide for hydrogen in a gas battery, but it puts a stop to hydrogen being used in one if mixed with it. Why this difference should obtain between the two gases, both being combustible, we scarcely know, although we may guess at the reason. Why carbonic oxide should hinder the electrolytic oxidation of hydrogen at present entirely passes comprehension. It is problems such as these, said Professor Armstrong, that we need to solve before any substantial advance can be made. No one, he continued, has yet succeeded in making a satisfactory voltaic battery with carbon, and before coal is burned electrically it will certainly be necessary to make it a conductor of electricity. "All these are tasks which we should aim at executing, whatever the difficulties in the way, the solution of such problems being of infinite importance to mankind."

Probable Earnings of the Hudson Tunnels.

In an estimate, submitted to W. G. Oakman, president of the Hudson Companies, by W. G. McAdoo, president of the Hudson & Manhattan Railroad Company, the probable earnings of the system are indicated as follows: Total net per annum, $3,810,000; fixed charges, $2,657,500; surplus, $1,152,000. Mr. McAdoo's figures are as follows:

77,000,000 passengers per annum (estimate of C. M. Jacobs, chief engineer, and Hugh Hazelton, electrical engineer) at 5 cents per passenger..................	$3,850,000
Cost of operation and taxes, at forty per cent (estimate of Hugh Hazelton, electrical engineer)	1,540,000
Net earnings from passenger traffic	$2,310,000
Net income from Terminal Buildings	1,200,000
Estimated income from baggage, advertising in cars and stations, news stands and other privileges, per annum.........	300,000
Total per annum..............	$3,810,000
Deductions from income:	
Interest on $53,500,000 Hudson & Manhattan Railroad first mortgage 4½'s (this amount estimated to be outstanding on completion of the lines) and $5,000,000 New York & Jersey Railroad 5's..................	2,657,500
Surplus	$1,152,500

ILLINOIS STATE ELECTRIC ASSOCIATION.

ANNUAL CONVENTION AT BLOOMINGTON, ILL., OCTOBER 27-28.

The Illinois State Electric Association held its annual convention at the Illinois Hotel at Bloomington, Ill., on October 27 and 28. In point of numbers of members attending and the character of papers presented, it was the best convention that has been held by the association. Special interest was shown in all the papers that were read because they had been printed before the convention met and then distributed to the members so that they were able to follow the speaker better. The weather the first day was disagreeable, but the second day turned out as fine as could be wished for. On the first day sixty-eight delegates had been registered.

President E. L. Brown of Elmwood called the convention to order on Tuesday morning, and in his address called attention to the loss of Senator John N. C. Shumway, former president of the association, who died during the past year. He also referred to the paper read before the National Electric Light Association by Mr. Doherty as to the advisability of the state organizations becoming part of the National Electric Light Association, by dropping their own name and becoming geographical parts of the national body. Speaking of governmental regulation of public utilities President Brown said: "It is easily apparent that regulation should come through the highest source possible, presumably a state board, as is in satisfactory operation in Massachusetts, Wisconsin and New York. Authority that would be removed from petty prejudice to the plane of the judicial, would have confidence of our customers, and be unlikely to place confiscatory regulations upon us. To be placed at the mercy of uninformed and transitory local officials would mean instability, endless friction and be a menace to growth and enterprise."

The first paper presented was that of J. J. Frey of Hillsboro, on "How to Finance a Small Electric Station." In this paper the methods of management that cause the failure of many small plants were briefly touched on. The author then considered the question of a new public service law and the good that would come through the appointment of a public service commission. The use of a uniform system of accounting was strongly urged so that costs could be compared in detail for similar plants.

Mr. Edwin O. Brown of Elmwood followed with a paper on "Extending Electric Service to Neighboring Towns." He described extensions of the plant at Elmwood, with which he is connected, to the nearby towns of Yates City, Brimfield, Douglas and Magnon. The longest transmission line is twelve miles, 6,600 volts being used. The entire system is laid out with great economy and is operating very successfully.

The afternoon session was opened by E. L. Smith, of Kewanee, who read his paper on "Elements of Cost of Service to the Consumer." He said that the subject was not given the attention that it deserved and that too many managers of small plants were in the habit of taking the coal cost as the cost of current. This was the case where the cost was given sometimes as only 1¼ cents per kilowatt-hour. He then gave a long list of items for both operation and maintenance that should be considered in making up the cost of the current, and the way that they might be classified so as to get the cost at the switchboard and the final cost to the consumer.

"The Advisability of Establishing a Day Circuit in the Small Town" was the subject of a paper by A. R. Manley of Mt. Carmel, who was unable to attend the convention. The paper was read by D. Davis of Litchfield. The paper was one of the best presented to the convention.

The author showed that the possibilities of the smaller localities are very frequently overlooked and neglected. While it is true that many electric light companies in the smaller towns have rather a precarious existence, this is due more to the companies themselves than to a lack of market for their product. Under anything like normal conditions, any town or city, large enough to have an electric light plant at all, can and will support a day circuit, if the opportunities for selling current are recognized and taken advantage of by the company. Most electric light plants, in towns having a population of 5,000 or under, operate either on a dark-to-midnight schedule, or, at the most on a dark-to-daylight basis. If a property remaining idle from twelve to eighteen hours of the day can be made to pay dividends, or even to meet its expenses, it would appear reasonable that, if an income could be obtained from the property during the full twenty-four hours, the profits would be much greater.

The fixed charges against the property and the depreciation are practically the same whether or not the day circuit is operated. The taxes, insurance, office expenses, etc., do not stop when the engines are shut down. The additional expenses of operating a day circuit are confined to the cost of fuel, supplies and an extra man or two. Briefly stated, all the income from the current sold in the daytime, over and above the cost of the extra fuel and supplies and the salary of the extra man or men, is profit.

All the conditions essential to the success of an electric-lighting plant are particularly so to one operating a day circuit. It is necessary to give continuous service, have a reasonable and fair rate and, most important of all, to have every service metered. It is advisable to give every patron on the lines the advantage of the day circuit—the opportunity to use current when he wants it. Under these conditions no flat-rate contract could be made that would be equitable to both consumer and central station, or that would not be abused.

Many helpful hints were given in the paper on how to bring the day service to the attention of the public and on how to conduct an aggressive campaign to further the introduction of motors, fans, signs, heating devices and all manner of electrical appliances for both industrial and household use. Reference was made to a plant whose load is practically the same summer and winter and after five years of constant advertising, constant solicitation, and which has brought the people to a point where electricity in the daytime has become a necessity and not a luxury. Every house that is built is wired and equipped, not only for lights, but for small heating appliances. The people are educated to a point where they apply for electricity for almost every purpose. The success of this plant is due largely to the fact that the service is absolutely dependable, the current not having been off the lines for more than four years. The rate is reasonable, averaging five cents for motor service and eight cents for lighting. The output has reached a point where the net profits from the day load are in excess of the profits from the night load.

During the discussion of Mr. Manley's paper the fact was brought out that, if it could be arranged so that the power user would take his maximum amount of power at a time when it would not interfere with the lighting load, or if he had what might be termed an off-peak load that could be handled without added cost as to equipment, he would be a great revenue producer, and an added benefit to all concerned.

The longest paper presented to the convention was read by George W. Burton, of Danville, on "The Legal Status of Transmission Lines in Illinois." The questions of law relating to this subject in Illinois are in many respects new. In the paper there were outlined the legal steps to be taken in the construction of a transmission line from one municipality to another, considering the situation within and without the municipal corporate limits, on highways and over private property, and with and without relation to individual and corporate property rights. These were discussed in connection with railway, telephone, telegraph and other electrical interests. A number of forms for frontage consents, pole line rights and municipal ordinances were appended to the paper. These were drawn so as to benefit the company by avoiding suits for damages.

In the discussion the matter of securing the whole of the right-of-way before commencing to build the line was shown to be a very important item as, if this is neglected and then the line is partly in operation, the expense of completion may easily become too great, for the property owners then have the company in their power and can demand too great a consideration for the small part that is needed to complete the line. The matter of using concrete poles came up during this discussion and Mr. Chubbuck called upon Mr. Miller, of Marseilles, who has been making them for a large system. He said they were made in molds in thirty, forty, forty-five and fifty-foot lengths. After being finished they were floated down the canal on a barge. As a pole thirty feet long weighed one and a half tons hauling them was a serious matter, and that the best way to do, where the conditions were not as favorable to their handling as they were there, was to haul the gravel and cement to the place where the pole was to be used and make it on the spot. The objection to this was the fact that it took twenty-one days for a pole to dry thoroughly, and during this time it would have to be lying there undisturbed and the conditions might make this impossible. After making the poles the holes were dug and the poles set by the use of a derrick wagon. Poles as made by him had six rods embedded in the concrete, one at each corner and the others nearer the center. Tests were made on the poles to determine how much they would stand. A pole was placed six feet in the ground, a rope attached to its top and the top deflected three feet with no cracks, the pole returning to the original position without a permanent deflection. When deflected four feet, it cracked at the bottom on the edges. Another test was made by attaching a rope to the top and fastening its other end to a tree, while between the two was hung a bag containing a mass of iron; this was jiggled up and down without any harm to the pole except a few small cracks on the edges.

At the request of the convention the subject of these tests and other information concerning concrete poles will be prepared into a paper for the use of the association. As to cross-arms for concrete poles some speakers advocated a concrete arm made integral with the pole while others suggested an iron arm, which was decided not to be as good on account of the rusting. The cost of these poles was given as double the cost of wooden poles; a thirty-foot pole costs $7.50 and a fifty-foot pole $12.50. These costs would vary as the cost of material and labor would vary in different localities.

The question of calling a line carrying high-tension wires a high-tension line was brought up, and it was agreed that in the future it would be better to call them long-distance transmission lines, and try to avoid the use of the term high tension, as enough opposition has been made to these lines already by the communities through which they pass or through which it is desired to erect lines.

On Wednesday morning Mr. McCollough, who was chairman of the committee to take action on the death of former President Shumway, read a set of resolutions at the opening of the meeting, and they were adopted and ordered to be placed upon the records and a copy sent to the family of the deceased. Senator Shumway was a charter member of the association, and much of the good accomplished by the association was through his untiring efforts. A report was received from the committee on the change in the by-laws calling for a fourth vice-president and an assistant secretary. It was adopted.

R. S. Wallace, of the Peoria Gas and Electric Company, then read a paper on "Rates and Their Relation to the Cost of Manufacture." This was believed by many to be the best paper read before the convention, but as it was not finished in time it was not in print before the session. The author had charts made and placed upon the wall to illustrate his remarks.

In this paper Mr. Wallace discussed the entire subject of rates and described the different systems of differential charging, giving examples of each. The fixed and variable costs were analyzed and their bearing on the equity of the rates made clear. Sliding scale or discount-for-quantity rates were condemned. Flat rates for sign and window lighting were approved, but in general meter rates are preferable for variable service. The author's general conclusions were: That the charge for service rendered should bear some relation to the cost of rendering it. Straight meter rates cannot possibly approximate the cost of service. Differential rates have been held equitable and legal in many decisions, and should be required where the difference in the cost of supply exists. As public servants, we must not favor one at the expense of another; that we must not sell to one at less than cost and make good our loss by excessive profits from another. While fully realizing the importance of acquiring and retaining the approval and confidence of the public, we must not, for the sake of popularity, sacrifice the basic principles which we know are essential to success, because there is public demand for something else.

During the discussion of the paper the fact was brought out that one rate could not possibly be fair to all consumers, as there are always different conditions governing the use of current as to the time when the maximum demand occurs and length of time when used. Various members gave their experience as to the rates they were charging and what success they had in securing the business and holding it. That it was an advantage to all concerned to have more electric power used, as someone in the electrical field was sure to benefit by it, a case was cited of several large stone quarries that were induced to use electric power, and while they were not served by a central station, they might some time be persuaded to be so served, and then someone would benefit by it, but at the same they were using the power now, and hence they were an addition to the electrical industry.

After this discussion the convention went into executive session and elected the following officers:

F. M. Sinsabaugh, Carrollton, president.

E. G. Schmidt, Springfield, first vice-president; W. G. Austin, Effingham, second vice-president; H. A. Foster, Fairbury, third vice-president; A. R. Manley, Mt. Carmel, fourth vice-president.

E. Macdonald, Lincoln, treasurer.

H. E. Chubbuck, Ottawa, secretary.

Chester A. Willoughby, Ottawa, assistant secretary.

Executive Committee: W. B. McKinley, E. G. Schmidt, J. F. Porter, F. J. Baker, E. L. Brown, and the president and secretary, ex officio.

The convention then adjourned. The location of the next convention will be determined by the executive committee at a meeting next June.

In the way of entertainment Tuesday evening was given over to social pleasures, various theater parties being made up and many old acquaintances renewed. On Wednesday afternoon the members and their friends took a car ride over the Illinois Traction Company's line to Peoria as the guests of that company.

There was present at the convention a small number of representatives of manufacturing and supply houses. Several members made the remark that as to the papers and the interest manifested it was the best convention they had attended, and also that they had been helped very much by attending, as all the papers were practical and helpful to their own properties.

Central Electric Railway Association.

A. L. Neereamer, secretary of the Central Electric Railway Association, announces that the next regular meeting of the association will be held at the Lima House, Lima, Ohio, November 19. The prospects for a large attendance and an interesting meeting are good. The Central Electric Traffic Association will hold its meeting at the same place the day preceding the regular meeting. On the latter occasion papers will be read on the following subjects: "Purification and Heating of Water for Feed for Boilers," by a representative of the Harrison Safety Boiler Works, Philadelphia, Pa. "Possibilities of Handling U. S. Mail and Compensation Paid by the Government," by G. M. Paxton, general manager Dayton & Troy Electric Railway Company, Tippecanoe City, Ohio. "The Claim Department," by Frank Talmadge, Columbus, Ohio. "Railroad Crossings," by W. C. Sparks, superintendent of tracks, Indiana Union Traction Company, Anderson, Ind.

Handling of Live Wires and Fire Streams.

On August 17, 1908, a meeting was held at Altoona, Pa., which was attended by officials and employes of the Pennsylvania Railroad to the number of about 200, at which instructions and demonstrations were given of (1) the method of, and the precautions to be exercised in, handling live wires, and (2) approved methods to be employed in resuscitation of those apparently dead from electric shock. In addition a series of tests was run to determine, for various voltages, the distance from live wires at which streams from fire hose and chemical extinguishers might be played on the same without injury to those handling the hose.

By reason of the increasing use of electricity along the lines of the Pennsylvania Railroad Company, it has become of great importance that employes have a better understanding of the personal hazard involved in the handling of live wires, so that the rescue and resuscitation of those suffering or who have suffered electric shock may not be delayed through ignorance or misconception. Lectures to employes on approved methods of resuscitation of those apparently dead from electric shock have been given in the past from time to time by the relief department, as a part of first-aid instruction. At such times brief instructions have been given on the recovery of bodies in contact with electric wires. It was decided, however, to go into more detail in this direction at the present time, before representatives of the various divisions, so that these representatives might in turn disseminate the information gained to employes under their charge.

A lecture and demonstrations on the methods to be used in resuscitation from electric shock was given in the forenoon on the above date by the local medical examiner, after which those present practiced the movements on each other to a considerable extent. In the afternoon, demonstrations of the proper methods of handling wires and playing of fire streams were carried out, suitable wires and apparatus having previously been erected for this purpose in a convenient location in the Altoona railroad yard.

HANDLING OF LIVE WIRES.

A pair of iron pliers, designed for use in cutting wires carrying high potential, was exhibited, and the essential features demanded were carefully pointed out. These consisted mainly in the insulation on the handles of the pliers, which is required so that no part of the hands or of the person manipulating them shall come in contact with any metal part of the pliers, which in turn comes into contact with the wire in the act of cutting. The insulated handles were of wood and were screwed securely onto the metal handles of the pliers, after which they were boiled in paraffine. The insulation was tested at 8,000 volts alternating, and successfully withstood this test. Equipped with these pliers, and standing upon a thin board, an operator cut several times a line which was lying on the ground carrying a potential of 2,300 volts—the other side of the wire being thoroughly grounded.

To illustrate methods which might be used to remove a wire from a body, in the event of pliers or other means of cutting the wire not being at hand, a coat was placed under the wire and held at either side by means of the sleeves; two persons are necessary for this maneuver. By this method the wire was raised from the ground, no effect being felt by the persons holding the coat, though the latter was somewhat damp.

EXPERIMENTS WITH FIRE STREAMS.

In order to determine definitely what hazard, if any, existed for firemen when they were compelled in line of duty to play water from fire streams on live wires at various potentials, arrangements were made so that circuits of 525, 2,300 and 4,600 volts, respectively, were available. The 525-volt line was a direct-current trolley wire connected to the lines of the Altoona & Logan Valley Electric Railway Company. The 2,300-volt and 4,600-volt lines were fed from alternating-current generators at the Altoona car shops. One side of each of these circuits was thoroughly grounded, and the fire stream played on the other side, which was suspended in the air and thoroughly insulated. A suitable voltmeter was connected between the nozzle and ground to enable the difference of potential between the nozzle and ground to be noted in each case. The following results were obtained, at the voltages specified below, in tests made the day previous to the general demonstration:

525-Volt Trolley Wire.
⅝-in. Nozzle.

Distance of Nozzle from Wire.	Potential between Nozzle and Ground.
7 ft. 5 in.	20 volts.
4 ft. 9 in.	38 volts.
3 ft. 7½ in.	60 volts.
2 ft. 2 in.	70 volts.
0 ft. 7½ in.	210 volts.

These results show that the nozzle may be handled without discomfort up to a point between three and four feet from the wire when those holding the nozzle are standing on the ground. It may be carried much nearer without harm, but would probably cause some discomfort. If those holding the nozzle were standing on a ladder or were otherwise insulated from the ground, it would be quite safe to bring the nozzle to within a few inches of the wire.

2,050-Volt Line.
⅝-in. Nozzle.

Distance of Nozzle from Wire.	Potential between Nozzle and Ground.
6 ft. 6½ in.	Static
3 ft. 5½ in.	Static

4,100-Volt Line.
⅝-in. Nozzle.

Distance of Nozzle from Wire.	Potential between Nozzle and Ground.
6 ft. 6½ in.	Static
3 ft. 5½ in.	Static

In each of the above tests no measurable deflection could be obtained on the voltmeter, but upon touching the nozzle with the hand when standing on the ground a slight effect due to static electricity was noted.

The above results were obtained in tests conducted a day previous to the general demonstration. In this demonstration, however, results were obtained which agreed with these. These results follow:

525-Volt Trolley Wire.
⅝-in. Nozzle.

Distance of Nozzle from Wire.	Effect at Nozzle.
3 ft. 0 in.	Slight Indication to hand.

2,300-Volt Wire.
1-in. Nozzle.

Distance of Nozzle from Wire.	Effect at Nozzle.
8 ft. 0 in.	Slight indication of static electricity to hand.

4,600-Volt Wire.
1-in. Nozzle.

Distance of Nozzle from Wire.	Effect at Nozzle.
10 ft. 0 in.	Slight indication of static electricity to hand.

In each case the nozzle was sufficiently near the wire so as to cause a solid stream to play on the latter. Just how far the results of a fire-hose test with salt water will differ from those above, which were made with fresh water, cannot be said at the present time.

Experiments were also made with streams from hand chemical extinguishers, and it was found that when a solid stream is played on a high-potential wire it becomes a source of danger to one holding the extinguisher. For instance, the nozzle of an extinguisher was held at a distance of nine inches on a grounded 2,050-volt alternating line. The difference of potential between nozzle and ground was 1,500 volts when the extinguisher was insulated from the ground.—*R. H. Newbern, superintendent insurance department, Pennsylvania Railroad Company, in the Quarterly of the National Fire Protection Association.*

International Conference on Electrical Units and Standards.[1]

On Thursday, October 15, the Technical Committee devoted the first part of the morning to the specification of the mercury ohm. The draft specification prepared by the Reichsanstalt was taken as the basis, and after alteration read as follows:

"*Specification A, relating to the Measurement of the Resistance of a Column of Mercury.*—The glass tubes used for mercury standards of resistance must be made of a glass which is as free as possible from elastic after-effects. They must be well annealed and straight. The tube must be of circular cross-section or nearly so of approximately one square millimeter. The mercury must have a resistance of approximately one ohm. The tubes must be carefully calibrated along their length by using threads of mercury of different lengths. The calibration factor must not exceed 1.0005. The mercury filling the tube at zero degrees centigrade must be considered as bounded by plane surfaces placed in contact with the flat ends of the tube. The length of the axis of the tube, the mass of mercury it contains, and the electrical resistance of the mercury, are to be determined at a temperature as near to zero degrees centigrade as possible. The measurements, when made, to be corrected to zero degrees centigrade. For the purpose of these electrical measurements end vessels carrying connections for the current and potential terminals are to be fitted onto the tube. These end vessels are to be spherical in shape (of diameter of about four centimeters) and should have a cylindrical piece attached to make connection with the tubes. The edge of the tube is to be coincident with the inner surface of the spherical end vessels. The leads are to be of thin platinum wire fused into glass. The point of entry of the current lead and the end of the tube are to be opposite ends of a diameter of the bulb; the potential lead shall be midway between these two points. The leads connected to the platinum wires must be so thin that no error in the resistance is introduced through conduction of heat. The filling of the tube with mercury for the purpose of the resistance measurements must be carried out under the same conditions as the filling for the determination of the weight. The resistance which has to be added to the resistance of the tube to allow for the effect of the end vessels is to be calculated by the formula

$$A = \frac{0.80}{1,063\,\pi}\left(\frac{1}{r_1}+\frac{1}{r_2}\right) \text{ ohm,}$$

where r_1 and r_2 are the radii in millimeters of the end sections of the bore of the tube. The mean of at least three fillings to be taken as the resistance of the tube. The mean result obtained from at least five tubes is to be taken as the mercury unit."

The final drafting of this specification was then referred to a drafting sub-committee, consisting of the chairman, Dr. Lindeck, Mr. Smith, and the secretary.

The committee then proceeded to consider Specification B for a standard silver voltameter. This was amended to read as follows:

"*Specification B, relating to the Deposition of Silver.*—The electrolyte should consist of from fifteen to twenty parts by weight of silver nitrate in 100 parts of distilled water. The solution may only be used once, and only for so long that not more than thirty per cent of the silver in the solution is deposited. The portion of the anode dipping into the liquid shall be of silver, and the cathode of platinum. The current density at the anode shall not exceed one-fifth of an ampere per square centimeter and at the cathode one-fiftieth of an ampere per square centimeter. Not less than 100 cubic centimeters of electrolyte shall be used in an experiment. Care must be taken that no particles which may become detached from the anode during electrolysis shall reach the cathode. Before weighing, any traces of solution adhering to the cathode should be removed, and the cathode itself dried."

This specification was then also referred to the drafting sub-committee, and the consideration of the specification of the Weston cell commenced. This was amended to read:

"*Specification C, relating to the Standard Cell.*—The cell to be taken as standard is the Weston normal cell, having an excess of stable cadmium sulphate ($CdSO_4 8/3H_2O$). The positive pole of the standard cell shall consist of mercury with mercurous sulphate as depolarizer;

[1] Electrical Engineer, London, October 23.

the negative pole to be of cadmium amalgam in the proportion of 12.5 parts by weight of cadmium to 100 parts amalgam. The electrolyte shall consist of an aqueous saturated solution of cadmium sulphate, neutral to congo red. The grains of mercurous sulphate must not be so small that an increase in the solubility and a consequent perceptible influence on the electromotive force may result; in addition, the solution from which the mercurous sulphate is precipitated must contain at least one-tenth gramme equivalent of strong acid; finally, the salt must be washed. The method to be employed must be one of those given in these notes, and the method must be closely followed. The depolarizer to consist of mercurous sulphate, mixed with powdered cadmium sulphate and a saturated, aqueous solution of this salt. For setting up the cell, the H form is the most suitable. The leads to the electrodes to be of platinum wire, which must not be allowed to come into contact with the electrolyte. The amalgam is placed into one limb after warming. The mercury is introduced into the other limb. The depolarizer is placed above the mercury, and a layer of cadmium sulphate crystals is introduced into each limb. The entire cell is filled with a saturated solution of cadmium sulphate, and then hermetically sealed. The following formula is recommended for the electromotive force of the cell in terms of the temperature:

$$Et = E_{20} - 0.0000406\ (t - 20^\circ) - 0.00000095\ (t - 20^\circ)^2 + 0.00000001\ (t - 20^\circ)^3.$$

The value of the standard cell to be the mean of at least twenty cells, which must be intercompared at least every three months, and which must be checked at least every year against the silver voltameter. Cells differing from the mean by more than 1.10^{-4} volt are to be replaced by normal cells."

In the afternoon the discussion turned on the value of the international ampere. It was eventually decided that "should the conference accept the figure 1.11820 milligram for the electrochemical equivalent of silver, then the electromotive force of the Weston cell at twenty degrees centigrade be provisionally accepted at 1.01820 volts."

On Friday, October 16, the conference met again, and considered the interim report of the Technical Committee. The length of the mercury column for the international ohm was confirmed as 106.300 centimeters. After further discussion Resolution VI was accepted by twenty-one votes to three. This reads: "The international ampere is the unvarying electric current which, when passed through a solution of nitrate of silver in water, in accordance with the specification attached to these resolutions, deposits silver at the rate of 0.00111800 of a gram per second."

Resolution II, amended as follows, was passed by the same majority: "As a system of units representing the above and sufficiently near to them to be adopted for the purpose of electrical measurements and as a basis for legislation, the conference recommends the adoption of the international ohm, the international ampere, and the international volt defined according to the following definitions:"

An additional resolution, "That the ohm is the first primary unit," was passed unanimously.

The conference then proceeded to consider the steps necessary to secure uniformity of the standards in future.

Professor Warburg moved: "That the conference approves generally the draft scheme to establish a permanent commission to secure uniformity of administration in relation to electrical units and standards in the future. The conference refers the draft scheme to the Technical Committee to consider details and to nominate the first members of the commission." He then explained his views as to the ways for obtaining uniformity. He said that there were two courses open, one to form a central bureau like the Bureau des Poids et Mesures which kept the international meter, and the second was that given in the draft proposals.

Construction of Selenium Cells.

Selenium cells, which vary their resistance with the intensity of illumination to which they are subjected, may be constructed in a variety of ways. A common form, easily made, is to wrap two wires upon an insulating core, keeping them separated by a uniform short distance, and then coat over the wires with a thin film of molten selenium. Another plan is to cover the surface of some solid, usually glass, with a thin coating of selenium. A difficulty met with in doing this, especially with glass, is the liability of the selenium to form into drops, instead of adhering uniformly. A new method recently devised in Germany by W. S. Grippenberg, causes selenium vapor to condense on the cold surface of the glass. In this way very thin and uniform coatings which adhere well to the glass are obtainable. Two grooves are cut in the glass close together and of as great a length as possible, and these are coated inside with platinum to act as electrodes.

Changes in the Western Electric Company.

At a meeting of the board of directors of the Western Electric Company, held in Chicago, on October 30, the following changes among the officers were made: E. M. Barton retired as president and became chairman of the board of directors; H. B. Thayer was elected president; H. A. Halligan and F. R. Welles were elected vice-presidents; William P. Sidley was elected vice-president and general counsel; George C. Pratt was elected secretary.

Mr. Thayer has been vice-president for a number of years, and has been connected with the company for twenty-eight years. He was born at Northport, Vt., August 17, 1858, and was graduated from Dartmouth College with the A. B. degree in 1879. He is a director of the Tabulating Machine Company and the Mexican Telephone and Telegraph Company, a member of the New York Chamber of Commerce, the New England Society, and the University Club. Mr. Thayer has had his residence in New York city, and will continue to reside there, and some of the engineering and other administrative work of the company will be conducted at New York. This is for the purpose of avoiding duplication between the Chicago and New York offices and between the engineering department of the company and the telephone companies, its principal customers.

Mr. Halligan has been for a number of years secretary of the company and in charge of a large part of the American business. Mr. Welles has been connected with the company for more than thirty years, and has charge of the foreign business, residing in Paris. Mr. Sidley has been acting as counsel for the company, and will continue to so act. His office of vice-president will not involve severing his connection with the firm of Holt, Wheeler & Sidley, of which he has been a member for some years.

The Western Electric Company is engaged in consolidating its manufacturing business at its Hawthorne plant in Chicago. It is removing to that plant the manufacturing heretofore carried on at Clinton street, in Chicago, and the principal portion of that which has been conducted at its factory in New York city.

Recent Sources of Electric Light.

The ordinary carbon-filament incandescent lamp, says Dr. L. Block, in the *Journal fuer Gasbeleuchtung,* which has been greatly improved during the thirty years of its existence, consumes from three to three and one-half watts per candle-power. A considerable saving in current consumption is effected by the use of lamps with so-called metallized carbon filaments. By being subjected to a peculiar fusing process at high temperatures these filaments receive metallic properties, particularly that of increasing their resistance with rising temperatures. The saving in current is about thirty-three per cent as compared with ordinary incandescent lamps, as the metal-filament lamps consume only two to two and one-quarter watts per candlepower and have an equally long life. The methods of manufacturing these lamps were practically developed first in America and then by the Allgemeine Elektrizitäts Gesellschaft, of Berlin. Their cost is not appreciably higher than that of ordinary carbon-filament lamps. In historical sequence the Nernst lamp was the first of the new kinds of incandescent lamps. In this lamp a small rod, consisting principally of combinations of the metal zirconium, which does not conduct electricity when cold, is made conducting by the application of external heat, and then glows with an intense, almost pure white light as soon as the current flows through it. The Nernst lamp consumes from 1.5 to 1.7 watts per candlepower and has a life of about 400 hours. Its current consumption is fifty per cent less than that of the ordinary incandescent lamp. It is particularly suitable for higher tensions, about 220 volts. Competitors of the Nernst lamp are the more recent metallic-filament lamps, the first of which was the osmium lamp, invented by Auer von Welsbach. The filament consists of the metal osmium, which is very difficult to fuse, and is also very expensive. The lamps consume about 1.5 watts per candle, and their life is about 1,000 hours, without any diminution in lighting power during this time. However, the price of the lamps was very high. They could burn only in a vertical position and were made only for low tensions, so that on a 110-volt circuit at least three lamps had to be burned in series, and at least five on a 220-volt circuit. The later metallic-filament lamps have now taken the place of the osmium lamp. The next lamp of this kind was the tantalum lamp of the Siemens & Halske Company. The metal tantalum can be drawn into very thin and still strong filaments, those used in the lamps being over one-half meter in length and wound on a frame in the form of a cage. The energy consumption of this lamp is about 1.7 watts per candle and its life about 800 hours. At present it is made for pressures up to 120 volts and is particularly suitable for direct current. The latest successes in incandescent-lamp manufacture are the lamps with filaments made of wolfram and similar metals. They are now manufactured for the usual tensions up to 130 volts, in units of twenty-five to 100 candlepower, and are put on the market by various concerns under many names, such as osram, osmium, colloid, sirius, Just-wolfram, colloid-wolfram lamps, etc. Their principal advantage is the small consumption of energy of only about one watt per candle, which means a saving of seventy per cent over ordinary incandescent lamps and of forty per cent over Nernst and tantalum lamps. At the same time the lamps have a life of about 1,000 hours without showing any appreciable decrease in light intensity. They are equally well suited for direct and alternating current. The first lamps of this kind could be used only in a vertical position, but they are now able to burn in any position. Their price is at the present time still about three marks (seventy-five cents), but in view of the great saving in current this higher cost is scarcely to be considered. In the arc-lamp field a greater light intensity and economy were attained by the so-called flaming arc lamps. The carbons used in these lamps contain, inside of a coat of ordinary carbon, a core consisting chiefly of fluor in combination with various metals. The vapors of these metals glow in the electric arc with an intensely luminous flame of 1,000 to 2,000 candlepower. The energy consumption of these flaming arc lamps is only 0.2 to 0.25 watt per candle, and the carbons last from ten to twelve hours. The gases are removed from the lamps by natural circulation of the air, and for this reason they are not suitable for illuminating small or badly ventilated interior rooms. A still lower consumption of energy, 0.15 to 0.2 watt per candlepower, and an almost pure white light are obtained in ordinary arc lamps by the use of the new "Alba" carbons of Siemens Brothers. In conclusion, mention must be made of the peculiar mercury light, which was introduced first in America by Cooper Hewitt. This is an arc of unusual length produced in a vacuum tube between surfaces of mercury. It has a remarkable green color, its efficiency is about the same as that of ordinary arc lamps, but the life of the lamps is about 1,000 hours. The quartz lamp seems likely to find the most extensive application among this type of lamps. The arc is here produced in a tube of quartz, which is capable of withstanding very high temperatures, and consequently the arc may be confined to a much smaller space and the light efficiency increased about twice that of the ordinary arc lamp. It is used directly on 220-volt circuits and can be operated only by direct current, like others of this type. A quartz lamp of 3,000 candle-power was exhibited. In appearance it resembles the flaming arc lamp. It is suitable for all purposes where the color of the light, which is a greenish yellow, is immaterial, and where a strong and economical light is required. On account of its long life, which is about 1,000 hours, the attention is reduced to a minimum, and so far the quartz lamp must be considered the only long-lived illuminant of great intensity.

The Alternating-Current Railway Motors of the Oerlikon Company and Their Effects on Telephone Circuits.

A lecture, delivered by Dr. Hans Behn on this subject before the Physical Society, of Zurich, is reprinted in the *Elektrotechnische Zeitschrift* for September 24. The opening of the first alternating-current electric railway in Switzerland, that between Seebach and Wettingen, was subjected to a protracted delay on account of serious disturbances caused in the nearby telephone lines. The experiences and the means which led to the removal of the difficulty are reviewed in detail. A theory of special upper vibrations of the electromotive force produced in commutator motors was established, as well as also a theory and calculation of the effects of these vibrations on telephone circuits. Other favorable experiences made with this line are discussed, and principles for the construction of larger alternating-current motors on the Oerlikon system developed. A complete calculation for an electric locomotive of 3,600-horsepower capacity, with four motors, is given. The disturbing influences on the telephone lines disappeared with the employment of a current of fifteen periods per second, and motors operating under this frequency were adopted and are generally recommended for railroad operation.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

THE GRISSON RECTIFIER.

An improved type of this alternating-current rectifier, with aluminium electrodes, which was first brought out in 1903, is here described. The former glass cell has been replaced by an iron cell in order to permit air cooling in place of the original method of cooling by water, which proved impracticable. It has also been found of advantage to give the aluminium electrodes an inclined position, so as to permit an easy escape of the hydrogen bubbles. The electrolyte consists of a solution of specially prepared bicarbonate of soda in pure water in proportions of one to sixteen parts. The rectifiers are furnished with electrodes already formed, but they have to be "polarized" before being put in operation, that is, the aluminium electrodes have to be provided with a coating of oxygen bubbles. Tables of the operation of a rectifier on a 110-volt alternating-current circuit of fifty periods per second under varying loads indicate a maximum efficiency of seventy-five per cent, and of seventy per cent on a 120-volt, fifty-period, polyphase circuit. By connecting the cells in series or multiple they may be used for any tension or current intensity and adapted to any purpose.—*Abstracted and translated from Elektrotechnische Zeitschrift (Berlin), October* 1, 1908.

NEW ANTI-INDUCTIVE SYSTEM OF CROSSING AERIAL TELEPHONE CIRCUITS.

With the introduction of the first long-distance electric transmission lines, disturbing influences on telephone circuits in their proximity were observed. They manifested themselves by rattling noises in the telephone receiver, and were at first ascribed to electromagnetic induction, but it was soon ascertained that they were due rather to electrostatic induction. This can be easily demonstrated by entirely suppressing the current in the energy transmitting line and leaving it only under tension. But whatever the cause may be, the most effective way of preventing these noises consists in reducing the coefficient of mutual induction between the disturbing and disturbed nets to a minimum. This result is attained by twisting the wires of one of the two nets, preferably the telephone wires. With the insulated conductors of an underground cable this twisting presents no difficulty, but it is different with bare aerial wires supported on insulators. The efficacy of the method has been thoroughly demonstrated in practice, but the various ways of applying it had numerous defects. A new system has been adopted by the Northern Railway of

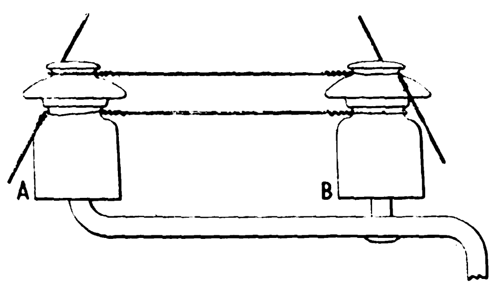

FIG. 1.—METHOD OF USING INSULATORS FOR TRANSPOSITION OF CONDUCTORS.

France, which was devised by its chief electrical engineer. In this system all the poles are uniformly provided with brackets carrying two insulators, as shown in Fig. 1. The insulators are of glass with a double bell and two recesses separated by a hood, the object of which is to insure perfect insulation between the two recesses. Fig. 2 shows the manner of put-

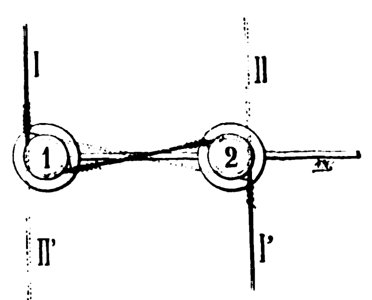

FIG. 2. METHOD OF USING INSULATORS FOR TRANSPOSITION OF CONDUCTORS.

ting the wires in place. Wire I makes a quarter turn in the lower recess of insulator No. 1, then goes to the corresponding recess of insulator No. 2 and passes on in the direction of I'. Wire II, represented by dotted lines, passes around insulator 1 and 2 in the same manner as wire I, but in the upper recesses. When the line has been put up, the conductors are held in place by binding wires. The effectiveness of this new crossing arrangement is evident, since it is only an artifice permitting a return to the original method. Double wire lines installed in this manner occupy space only in width and allow a utilization of the poles to their maximum capacity. The system has been tested for over a year on several long-distance telephone lines belonging to the Northern Railway Company of France, which frequently run parallel to high-tension transmission lines, and the results have been satisfactory in every way. The article concludes with a table indicating the number of crossings per kilometer which it has been found best to employ with different tensions and distances of the disturbing line.—*Abstracted and translated from L'Electricien (Paris), October* 10.

A RAILWAY ACCUMULATOR CAR.

Louis Dubois describes a new type of storage-battery car which has recently been put in operation upon the system of suburban lines around Mayence, under the direction of the Prussian Railroad Administration. A few cars of this design have been installed, and a favorable impression made. It is expected that a larger number will be called for in the near future. There are three suburban lines which branch out from Mayence and run as far as the towns of Oppenheim, eleven miles; Russelheim, seven and one-half miles, and Ingelheim, eleven miles, making a total of twenty-nine and one-half miles for the entire system. The present railroad is operated at speeds which vary between twenty and thirty miles an hour, and there are a number of intermediate stations on the route. The car is of the side-opening compartment type, and contains six compartments with seats on each side. The compartments are designed to hold ten persons each, and in general construction the car resembles the type which is used at present on the Berlin subways. The car is mounted on three axles of the ordinary kind without the use of bogies, and the over-all length between buffers is forty feet. The motorman's cab is raised considerably above the floor level, and there is a cab at each end of the car. The accumulators are stowed under the seats of the car in each of the compartments. The batteries are of an improved type brought out by the Accumulatoren Fabrik of Hagen. Under each seat there are permanently placed two large boxes, which are protected by the front board of the seat, this being fixed by screws. The top of the seat is hinged and can be easily raised and held in this position by a catch when it is desired to inspect the battery connections. The two boxes contain seven and eight cells, respectively, making thirty in each compartment. The entire car holds 180 cells, which is found to be amply sufficient to run it under the present conditions of speed and gradient. The cells have a capacity of 2,300 ampere-hours at the 100-ampere discharge rate. With a single charge the 180-cell battery can cover a distance of thirty-six miles when running at a speed of twenty-four miles an hour, which is about the maximum speed used on the Mayence lines. With this capacity the car can make two trips to the suburbs and return without recharging. Upon returning to Mayence after the second trip the battery is charged in place by means of a flexible cable which is fitted into a charging plug at one end of the car. The battery is not removed except for making repairs. Each cell weighs 100 pounds complete. The positive and negative plates measure twelve by twelve inches, and have a thickness of about three-tenths of an inch. There are four positive plates per cell. The plates are separated by wood and gutta-percha strips, and are hung upon glass by lugs, leaving a space of about two and one-half inches under the plates. The cell boxes are of wood, which is specially treated and given an outer coating of acid-proof varnish. Connection is made to the terminals of each cell by means of a copper strip, which is, in turn, protected by a coating of lead. In order to keep the fumes out of the car, the top of the seat is provided with a rubber gasket, and the space under the seat is ventilated by a tube which projects from the car and gives a good supply of air to the interior. The 180 cells represent a total weight of about ten tons. They are able to furnish 68.5 kilowatts on a single discharge, as shown by official tests. Their energy capacity is 6.85 watt-hours per kilogram. The life of the positive plate is estimated at 62,500 car-miles, and that of the negative plate at 37,000 car-miles. On the front and rear axle twenty-five-horsepower motors are arranged for series-parallel control, with a gear ratio of one to 4.3. Eighty-four per cent efficiency is claimed with a total weight per motor of 2,600 pounds, including the gears and casing. The batteries may be charged in a single series of 180 cells, or in two groups of ninety cells coupled in parallel. The car, when fully loaded, weighs twenty-two tons. The motors weigh 2.4 tons, and the battery ten tons, making about thirty-five tons for the entire weight. The cost of the battery is $3,250, and that of the electric outfit $2,750. The car costs $750, making the total cost of the present outfit $6,750.—*Abstracted from the Electrician (London), October 16.*

AN ELECTRIC COLLIERY RAILWAY.

The electric railway at the Consett Iron Company's Chopwell colliery is interesting chiefly as being the first installation of its kind in the north of England. The innovation reflects great credit upon the company's mining engineer, F. O. Kirkup. The line connects the Chopwell colliery with a new winning at Whittonstall, about two and one-quarter miles distant. The coal at Whittonstall is loaded into tubs, which are made up into a train of thirty-six, and hauled by means of an electric locomotive to the screening plant at the Chopwell colliery. In this way the installation of a large amount of new and expensive stationary plant is avoided, and it is possible to work new isolated seams economically. The line is two and one-quarter miles long, with a maximum gradient against the load of one in twenty-four. The length of the maximum gradient is about 720 yards, and the average gradient against the load is about one in forty-seven. The load to be hauled, exclusive of the locomotive, is twenty-five tons; the time allowed for each journey ten and three-quarter minutes, and two double trips per hour are expected. The track is of twenty-six-inch gauge. For these conditions a powerful locomotive is necessary, and the narrowness of the gauge imposes severe restrictions on the motors. The body of the locomotive is supported on two bogie trucks, each equipped with a single fifty-six-horsepower, 500-volt Siemens railway motor. The aggregate capacity is 112 horsepower. The two axles of each bogie are connected together by side rods, in order to utilize the whole weight of the locomotive for adhesion. One of the axles is driven through spur gearing by the motor. This gear consists of two equal gear wheels and one pinion, the pinion being fixed on the motor axle, one gear wheel on an intermediate shaft, and one on the driven axle. The locomotive body is built up on two main longitudinal steel girders, which are themselves supported by cross beams from the bogie centers. The space between the bogies is utilized for the lower part of the driver's compartment. In this way the height of the locomotive is reduced, so that the line can be taken under a roadway without excessive excavation. Current is collected by two Siemens bow collectors of such a length as to allow of a considerable range in the height of the trolley wires. The track consists of fifty-pound Vignole rail. Each rail is thirty feet long, and they are bonded by means of a single bond at each joint. Power is supplied to the locomotive from a 200-kilowatt, direct-current, compound Siemens generator, coupled direct to a Belliss engine. The power house is situated about 600 yards from the railway, near the Chopwell end, and is connected to the overhead line by means of two positive and one negative insulated feeders running through earthenware pipes in a trench.—*Abstracted from Electrical Engineering (London), October 22.*

Civil Service Examination for Electrical Engineers and Draftsmen.—Office of Supervising Architect.

The United States Civil Service Commission announces an examination November 23 to 25, at the usual cities to fill a position of electrical engineer and draftsman in the office of the supervising architect, Treasury Department, Washington, D. C., at $1,200 per annum, and similar vacancies as they occur. The examination will be weighted as indicated: Mathematics to plane trigonometry, 10; theoretical and practical questions in electrical science (special reference to lighting and elevator work in public buildings), 20; drawing and design, 40; training and experience, 30. Three days of seven hours each will be allowed for the examination. Applicants should at once apply to the United States Civil Service Commission, Washington, D. C., for application form 1312.

Report of Earnings of the Northern Ohio Traction and Light Company.

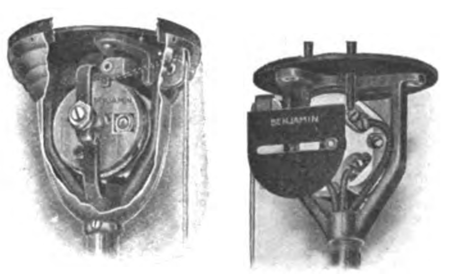
The report of the Northern Ohio Traction and Light Company for the nine months ended September 30 shows gross earnings of $1,421,549, against $1,459,-782, net of $598,506, against $627,197 and surplus of $206,502, against $244,-036. The earnings for October are estimated to be about the same as last year, and for the balance of the year will be able to show increases.

INDUSTRIAL SECTION

ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

Some New Benjamin Specialties.

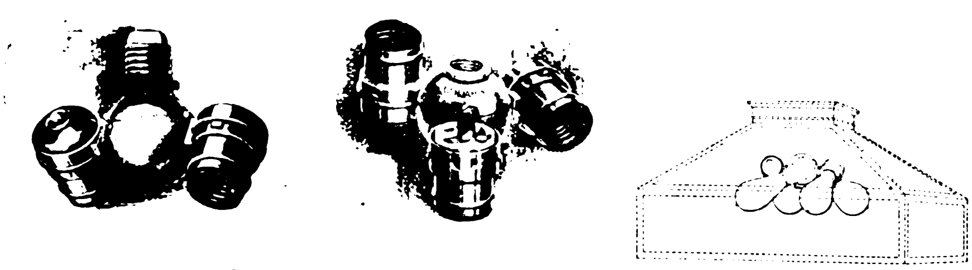
The Benjamin Electric Manufacturing Company, 42 West Jackson boulevard, Chicago, Ill., is placing on the market several new National Electrical Code Standard lighting specialties. The illustrations herewith show two grouping canopy switches with auxiliary pulleys. The Benjamin grouping canopy switch is



BENJAMIN GROUPING CANOPY SWITCHES.

adapted for conveniently and economically locating the control of any lighting fixture or bracket in which a plurality of lamps is to be operated in two groups. Two or three degrees of illumination may thus be secured without the necessity of running the usual three wires to the switches on the side walls or using two pendant switches. The controlling pendant cord or chain is dropped directly from the canopy, or it may be carried to any desired point by the use of an auxiliary pulley. Binding posts are provided in the switch for the two leading-in wires and the three other wires extending through the stem to the fixture body. The mechanism is substantial in character and is entirely enclosed. The canopy is provided with a fiber insulating ring. It has a margin of one-half-inch play to allow for projecting outlet boxes.

The illustrations herewith also show some uew Benjamin adjustable plug and socket clusters designed for use with ceiling or pendant dome fixtures, stand lamps in dining rooms, reading rooms, or other installations, where it is desirable to adjust and fix the lights in special relation to the sides of the dome or reflector. The socket may be turned to any position between two points, 180 degrees apart, and locked by means of a screw. By removing the socket cap, easy access is gained to the binding screws. These clusters are easily wired, and are finished ordinarily in polished brass.



BENJAMIN ADJUSTABLE SOCKET CLUSTERS.

Curve-Drawing Instruments for Alternating and Direct-Current Circuits.

Curve-drawing instruments which will indicate the load conditions of central stations are a necessary addition to the modern switchboard. The General Electric Company has produced for this service a complete line of voltmeters, ammeters, single and polyphase wattmeters and power-factor indicators for alternating current, and ammeters, voltmeters and wattmeters for direct-current circuits.

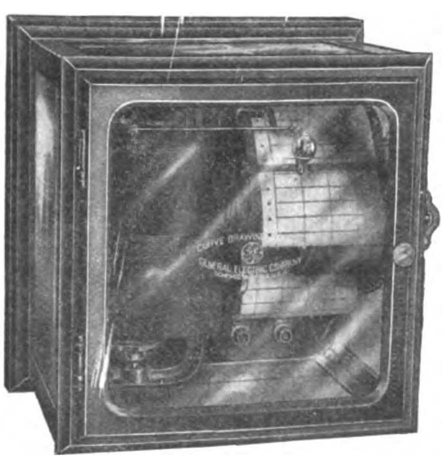
As in all instruments for measurement, continued accuracy is the principal requirement, and its importance has been kept in view in the design of these instruments. Friction is almost entirely reduced to that of the recording pen on the paper. The moving element is entirely suspended by a steel piano wire, the lower end being accurately centered by a small hardened steel pivot passing through a ring-stone sapphire jewel. A device is also provided for holding the moving element and pen arm firmly in place during shipment.

The pen depends for its action upon the principle of capillary attraction. It has an iridium point sealed into a very small glass tube, which in turn is placed inside of a larger tube, the latter terminating in a bulb which holds sufficient ink to operate the pen seven days without refilling. The record is made on a band of specially prepared paper sixty feet in length. On this paper are ruled lines corresponding to the time and to the instrument calibration; ordinates across the paper indicating time and those ruled lengthwise representing volts, amperes, watts, power factor, or other quantity indicated by the instrument. This form of chart has the advantage of permitting the use of time divisions of equal length throughout the entire range of the recording pen. The recording pen is attached to the moving element in such a manner that its motion is transmitted in a straight line parallel to the time divisions on the chart, and the record or diagram thus produced is much easier of interpolation than that produced by instruments that have lines which are curved or of unequal length.

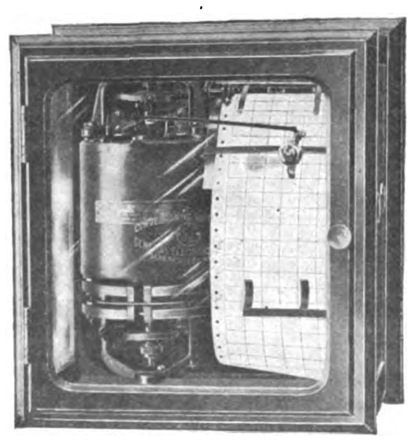
As the paper is unwound and passed under the recording pen, it is paid into a space at the bottom of the instrument case. The instrument case is provided with a cutter which enables the paper to be torn off evenly and without damage. When a roll of paper is exhausted the empty wooden holder can be easily removed by withdrawing it from the spring-supporting trunnions. A new roll can then be placed in position on the supporting trunnions, and the end of the paper carried over the idler roll at the back of the case. The pen arm is moved back from the paper by simply lifting it, which at the same time locks it into position, where it remains until loosened.

The standard rate of chart feed is three inches per hour, although a feed of one inch or six inches per hour can be furnished if desired. The rapid feeding of recording instrument charts is of great importance, as it insures a clear, accurate record that cannot be obtained with slow-moving charts. For driving the chart an eight-day clock, of simple and rigid construction, is used. It is self-contained, easily regulated and an accurate timekeeper. By means of suitable gearing, the clock drives a drum having peg teeth which engage the holes located near the edge of the chart. These teeth not only feed the paper under the recording pen, but also give it a definite and accurate position along the axis of the drum. The feeding drum is driven by a friction clutch which can be operated either forward or backward. This enables the paper to be accurately located in regard to the time graduations without difficulty or without strain to the driving gears and clock. If desired, a re-roll attachment can be furnished with these instruments. By means of this device, the chart is rewound as it passes from the drum after the record has been made. The re-roll is revolved by means of a separate spring attachment, releasing the clock from any extra strain.

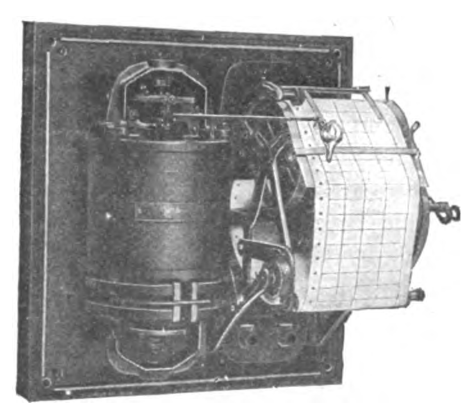
The electrical characteristics of these instruments are also excellent. The torque or directive force is very high, thus insuring long life with continued accuracy. The pen arm fluctuations are magnetically damped by means of a disk of aluminum passing between the poles of permanent magnets. This method of damping is very effective, introduces no friction, and is free from the objectionable features common to air or liquid damping systems. The instruments are thoroughly shielded from the influence of external magnetic



DIRECT-CURRENT CURVE-DRAWING AMMETER.



ALTERNATING-CURRENT CURVE-DRAWING WATTMETER.



ALTERNATING-CURRENT CURVE-DRAWING WATTMETER WITH RE-ROLL ATTACHMENT.

fields. This desirable feature is accomplished by the use of a laminated soft-iron shell which completely surrounds the measuring coils. These instruments are free from heating errors and may be used on circuits of any wave form or power factor.

Ammeters, power-factor indicators and single-phase wattmeters are made in capacities up to and including 200 amperes and 650 volts, for use without current or potential transformers. For circuits in excess of the above, current and potential transformers must be used. Voltmeters are made in capacities up to and including 750 volts without potential transformers, which are required, however, above this limit. Polyphase wattmeters with current capacities up to and including sixty amperes and with potential capacities up to and incluuding 650 volts, are made for use without current and potential transformers. On circuits where the voltage and current exceed the above limits, current and potential transformers must be used.

Direct-current curve-drawing ammeters are constructed upon the astatic principle, and are of the electromagnet type. The moving element consists of two rectangular-shaped coils connected together with two soft sheet-steel astatic control pieces fastened between them. The current to be measured, or a shunted portion of it, is passed through the coils, which are free to move in the field set up by two astatically arranged electromagnets. These magnets are wound standard for 125-250 and 550 volts, and the instruments are so designed that a twenty-five per cent variation above or below normal will cause no appreciable error in the instrument indications. The movement of the coils is opposed by the counter-torque of the astatic control pieces, and also by the control springs.

Direct-current ammeters are made self-contained in capacities up to and including sixty amperes. Instruments with capacities from eighty to 3,000 amperes are provided with external shunts and can be furnished of higher capacities if desired. All of the shunts used with these instruments have a uniform drop of sixty millivolts, and capacities in excess of 800 amperes are provided with a special thermo-electric attachment, which is designed to eliminate errors due to thermo-electric currents. Both the alternating and direct current instruments are finished in dull black, and are enclosed in glass cases and fitted with felt guards or cushions to make them dust-proof.

Feed-in and Strain Support for Feeder Cables.

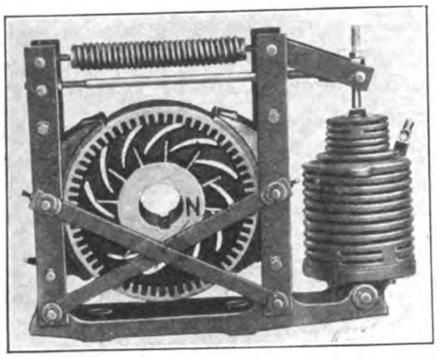
A new and improved combined feed-in and strain support for trolley feeder cables has been brought out by Dossert & Co., Incorporated, 242 West 41st street, New York. The device, as shown in the accompanying illustration, comprises a combination of the Dossert solderless cable

FEED-IN AND STRAIN SUPPORT FOR FEEDER CABLES.

tap with a regular soldered ear of the cap and cone type. The feed-in tap is made with a standard threaded stud which screws into the ear. A jamb-nut and lock-washer holds the feed-in tap securely in place against the boss of the ear. The advantages claimed for the Dossert feed-in are that it eliminates the process of soldering the feeder cable or fastening it with screws, gives contact throughout its entire length instead of at three points, as in case of a yoke, does away with bending and "checking" of the feeder by receiving it in a perfectly straight line, acts as a strain support, is strong and compact, and cannot work loose. The tap is bored to take up to No. 0000 round wire or stranded cable, and can be furnished with five-eighths-inch or three-fourths-inch stud.

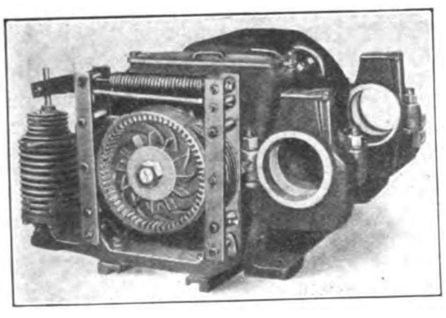
Electric-Motor Friction Brakes.

The Westinghouse Electric and Manufacturing Company, Pittsburg, Pa., has developed several types of electric-motor friction brakes for the many applications of motor drive where it is necessary to



REAR VIEW. TYPE SP BRAKE.

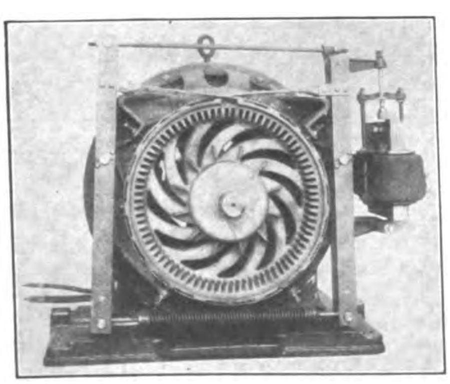
make quick and accurate stops. In rolling mills, blooming mills and similar installations, where frequent stops and reversals are necessary, brakes are needed to save time in bringing the motors to



TYPE SP BRAKE ATTACHED TO WESTINGHOUSE TYPE MD MILL MOTOR

rest before reversing, and to assist in the accuracy of control.

These brakes are built for both alternating and direct-current motors, and are operated by electromagnets, the coils of



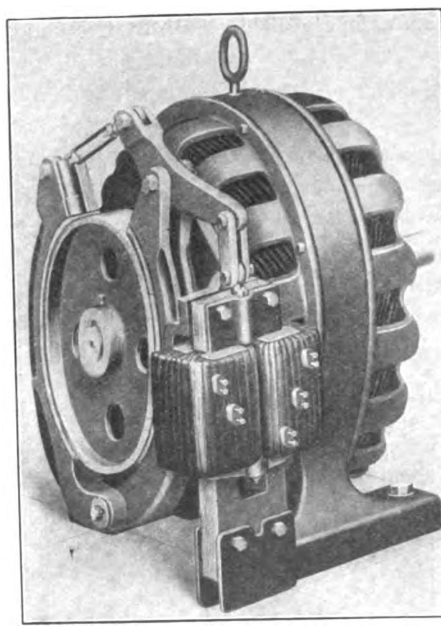
TYPE PB ALTERNATING-CURRENT MOTOR BRAKE.

which are connected in series or in shunt with the motor circuit. Series coils are used almost entirely with direct-current motors, and give more satisfactory service than shunt coils, although the latter can be supplied if desired. Alternating-current brakes are equipped with shunt coils only. These are connected across one phase of the motor circuit.

The type QK brakes are used on Westinghouse type K direct-current motors operating cranes, hoists, etc. These brakes are attached to the motors by means of special bearing housings carrying brake pads.

The type QBK brakes are similar to the type QK brakes in all respects, except that the former are mechanically operated, and are particularly adapted for use with the bridge travel motors of traveling cranes. These brakes are connected to the crane cage by suitable rods, and the braking force is applied by the crane operator.

The type SP brake has been designed primarily for steel-mill work, but can be



TYPE FS BRAKE ATTACHED TO WESTINGHOUSE TYPE HF MOTOR.

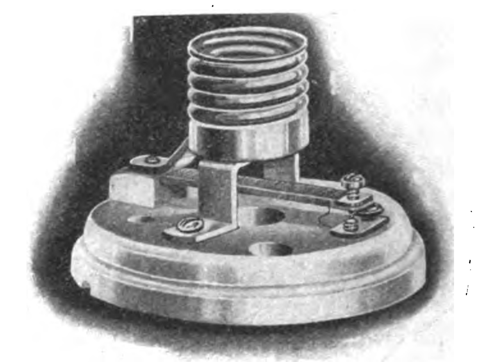
used in any service where a strong, rigid construction is desired. All parts are liberally proportioned, having a factor of safety large enough to meet the severest operating conditions. The brake is designed for mounting on the Westinghouse type MD mill motor, but can be used with other motors if desired.

The type FS alternating-current motor brake is adapted for twenty-five and sixty cycles, two and three-phase motor circuits.

Type PB alternating-current motor brakes are made for Westinghouse two and three-phase induction motors of from five to 100 horsepower, twenty-five, forty and sixty cycles. The braking action depends on the contraction of a coiled spring, and the brake will operate equally well with the motor tilted at a considerable angle from the horizontal position, as on roller lift drawbridges. This brake is attached to the motor in the same manner as the type FS, requiring a special bearing bracket and shaft.

A New Flashing Socket—the "Firefly."

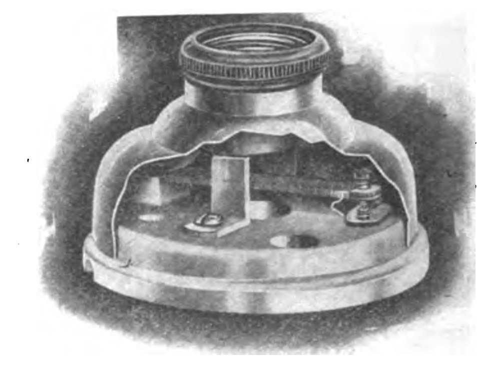
The reliability and usefulness of small thermostatic flashers, operating upon the principle invented by Dr. C. O. Schneider, of Chicago, about five years ago, has been



"FIREFLY" SOCKET FLASHER, SHOWING ARRANGEMENT OF PARTS.

amply demonstrated by the constantly increasing sales of the "Firefly" flasher, and also by the many cheap imitations of this simple little instrument that have appeared on the market at different times.

Realizing the desirability of a compact unit, containing both the flashing mechanism and a receptacle for the lamp, C. O. Schneider & Company have now devised



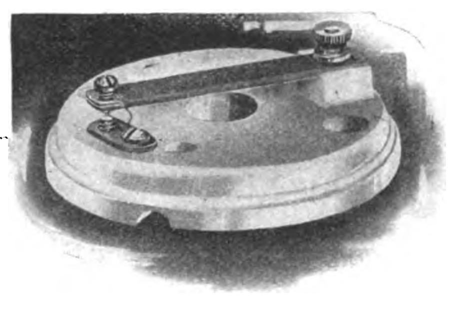
"FIREFLY" SOCKET FLASHER, WITH RING REMOVED.

the "Firefly" flashing socket, which is illustrated herewith.

The flashing mechanism in the socket is the same as the regular "Firefly" only much reduced in size, and it operates equally as well as the larger instrument. The iridio-platinum contacts will be the same size as are being used in the original flasher, therefore they anticipate the same satisfactory long-lasting qualities of the new flashing sockets.

The flashing socket may be connected with the same facility as an ordinary socket, it being merely necessary to unscrew the insulating ring, to lift off the cover, insert the wires through the porcelain base, fasten them to the binding screws and replace the cover and ring. Any lamp may be screwed into the socket, even up to a 100-candlepower tungsten. After waiting a minute until slightly warm, it will begin to flash the light on and off automatically from twenty to thirty times a minute, for a year or two.

Thermostatic flashers are now very extensively used to operate lamps in small electric signs, for attractive window-trimming effects, for displaying new types of lamp, decorative lighting, Christmas tree lamps, etc. In some forms of small signs made of all glass and metal, the flashing socket can be used without the ring and cover, as shown in the illustration. Another illustration shows the same flashing mechanism without the lamp socket; this will be known as the "Midget" flasher.



"FIREFLY" FLASHER USED WITHOUT RING AND SOCKET.

The great majority of thermostatic flashers in use at the present time are required to operate only a single lamp, and for this reason the flashing socket should meet an already existing large demand.

Schureman Alternating-current Elevator Controllers.

The J. L. Schureman Company, of Chicago, which for the past fourteen years has specialized in the design and construction of self-starters and elevator controllers, and whose direct-current apparatus is in general use throughout the country, has recently perfected a complete alternating-current line which is distinctive in that it conforms to the best principles in self-starter design, as developed in direct-current practice, by employing solenoids to perform all the functions of connecting the motor to the line and bringing it up to speed.

The line is complete in every respect and includes remote-control switches, self-starters for all classes of pump and compressor work, and elevator controllers for all services. Only one type, the reversing controller for slow-speed freight elevators, will be described at this time.

To obtain the best results and to avoid injury to the motor or controller through ignorance of the operator, the controller should be positive in action. After the rope has been pulled to start the elevator, the acceleration of the motor should be regulated entirely by the controller and should not be subject to the will of the operator. Also, in case of a failure in voltage through an interrupted circuit of any kind, it is unsafe to rely upon the judgment of the operator to return the controlling rope to the off position. To guard against accident in such a case the controller should be provided with a no-voltage release, which insures the return of the controller to starting position on failure of voltage.

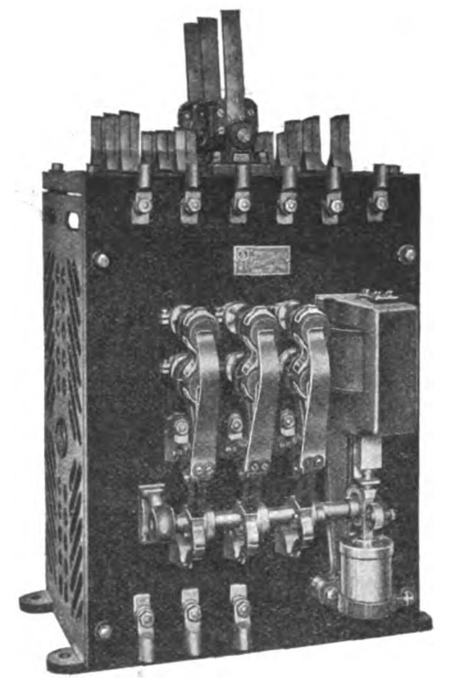
These controllers employ the resistance method of starting, and are especially adapted to slip-ring two or three-phase motors, such as are generally used for elevator service, on account of the high starting torque required. They have been successfully used, however, with squirrel-cage motors with high-resistance windings and comparatively high-torque characteristics.

The construction and operation of the controller is very nearly the same for either class of motor, the essential difference being in the rheostat. In the slip-ring type the starting resistance is of course inserted in the rotor circuit, is star-connected for three-phase motors and is inserted in all three phases. In the squirrel-cage type the resistance is inserted in two phases of the stator circuit and is cut out by the rheostat switches operating in pairs.

Fig. 1 shows a fifteen-horsepower, 220-volt, three-phase type "ASF" controller for a motor of this type. It is constructed along the same general lines as the "Schureman" direct-current freight elevator controller and consists of a solenoid-operated rheostat for accelerating the motor, and a knife-type reversing switch.

The method of operation is extremely simple. The shaft of the reversing switch is geared suitably to the operating mechanism of the elevator. A movement of the shipper rope sufficient to produce a throw of ninety degrees on the switch shaft closes the reversing switch and starts the motor in the direction for either up or down movement of the car, as desired, depending on the direction of pull on the rope, and the consequent direction of rotation of the switch shaft. This switch not only closes the stator circuit of the motor and connects the latter directly to the line, but also acts as a pole changer and controls the direction of rotation by reversing two legs of the stator circuit. It also controls the circuit of the rheostat solenoid, and when closed this solenoid is instantly energized and completes the operation of the controller by cutting out the starting resistance in the rotor circuit and bringing the motor to speed.

The construction of the controller is simple and rugged throughout, all parts being made interchangeable for easy replacement. The rheostat consists of a series of short-circuiting switches, a solenoid and dashpot. As the plunger of



FIFTEEN-HORSEPOWER, 220-VOLT TYPE ASF CONTROLLER.

the solenoid is raised, it revolves a horizontal shaft through the medium of a rack and pinion. A series of cranks placed at fixed positions on the shaft operate the switches, closing them in succession, and short-circuiting the starting resistance. The switches are three-point, and each short-circuits one step of resistance in each phase. In this way the resistance in each phase is equal at all times and the circuit is never unbalanced. This insures uniform torque and maximum efficiency. A vacuum dashpot retards the movement of the solenoid plunger and can be adjusted to give the desired rate of acceleration.

The solenoid is of special construction, the pull being practically constant throughout the stroke, and is practically noiseless in operation. It is designed to withstand severe service without undue heating.

Electrodeposition of Brass.

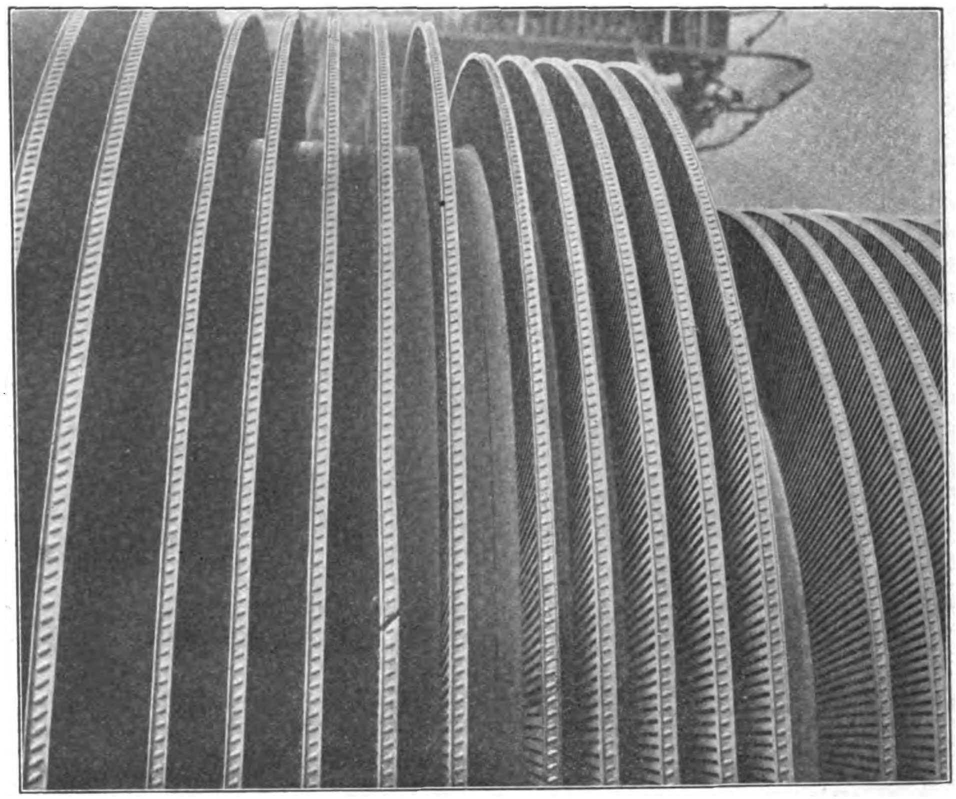
In the electrodeposition of brass and similar alloys the chief difficulty which has heretofore been experienced in practice is to obtain for any length of time an alloy of the desired composition. The composition of the alloy can be regulated within certain limits by varying the relative percentages of the metals in solution through the adjustment of the temperature of the electrolyte and the current density with the corresponding increase or decrease in voltage and moving the cathode, but this regulation is not sufficient in cases where it is desired to deposit an alloy of any thickness, for instance, to produce brass sheets or tubes.

As the result of an invention that was recently patented Mr. Sherard O. Cowper-Coles, of London, England, provides means whereby the composition of the alloy deposited can be more effectually controlled. His process consists in employing, in addition to an anode of the alloy to be deposited, say brass, anodes of copper and zinc which can be connected to the circuit which supplies the current passed through the brass anode. Furthermore, resistances are inserted in the conductors which convey the current to the zinc and copper anodes, whereby the amount of current flowing through these anodes, and as a consequence, the amount of metal that goes into the solution, can be regulated.

The inventor has found that good results can be obtained in practice with such an arrangement of anodes by employing an electrolyte composed of double cyanides of copper and zinc and potassium. He has obtained excellent results with an electrolyte prepared as follows: A ten per cent solution of cyanide of potassium is brought to the point of saturation by passing an electric current through a brass anode, the cathode being protected by a porous pot, and the electrolyte being then worked under the condition already mentioned, small quantities of cyanide of potassium being added from time to time to maintain the strength of the solution.

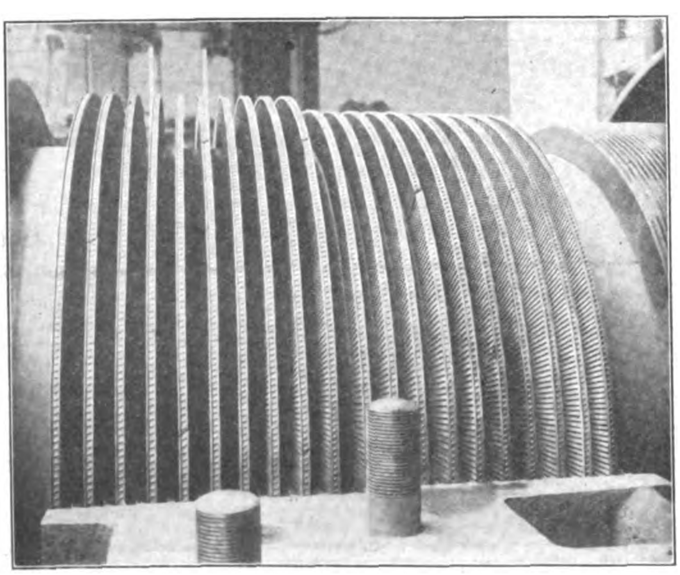
Remarkable Performance of Allis-Chalmers Steam Turbine.

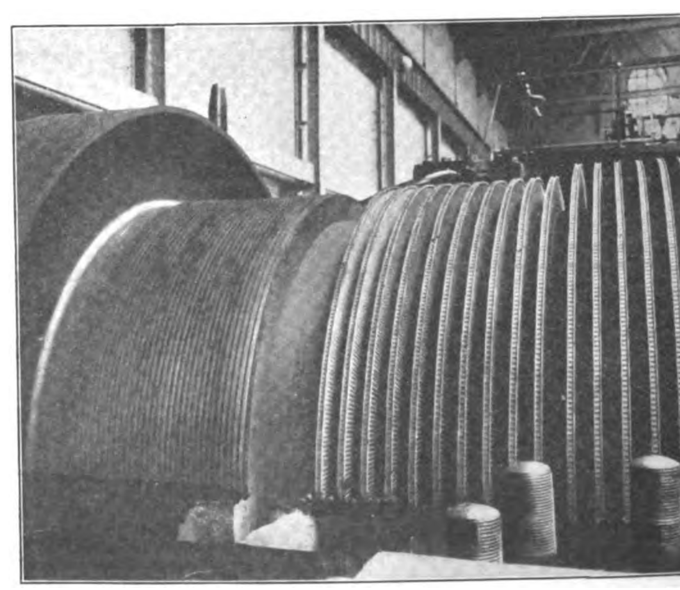
The accompanying illustrations have been made from photographs which were taken of a 5,000-kilowatt Allis-Chalmers



A NEAR VIEW OF THE BLADING OF ALLIS-CHALMERS STEAM TURBINE AFTER TWENTY-SEVEN MONTHS' CONTINUOUS SERVICE.

steam turbine which was opened up recently at the power house of the Brooklyn Edison Company, in Brooklyn, N. Y.,

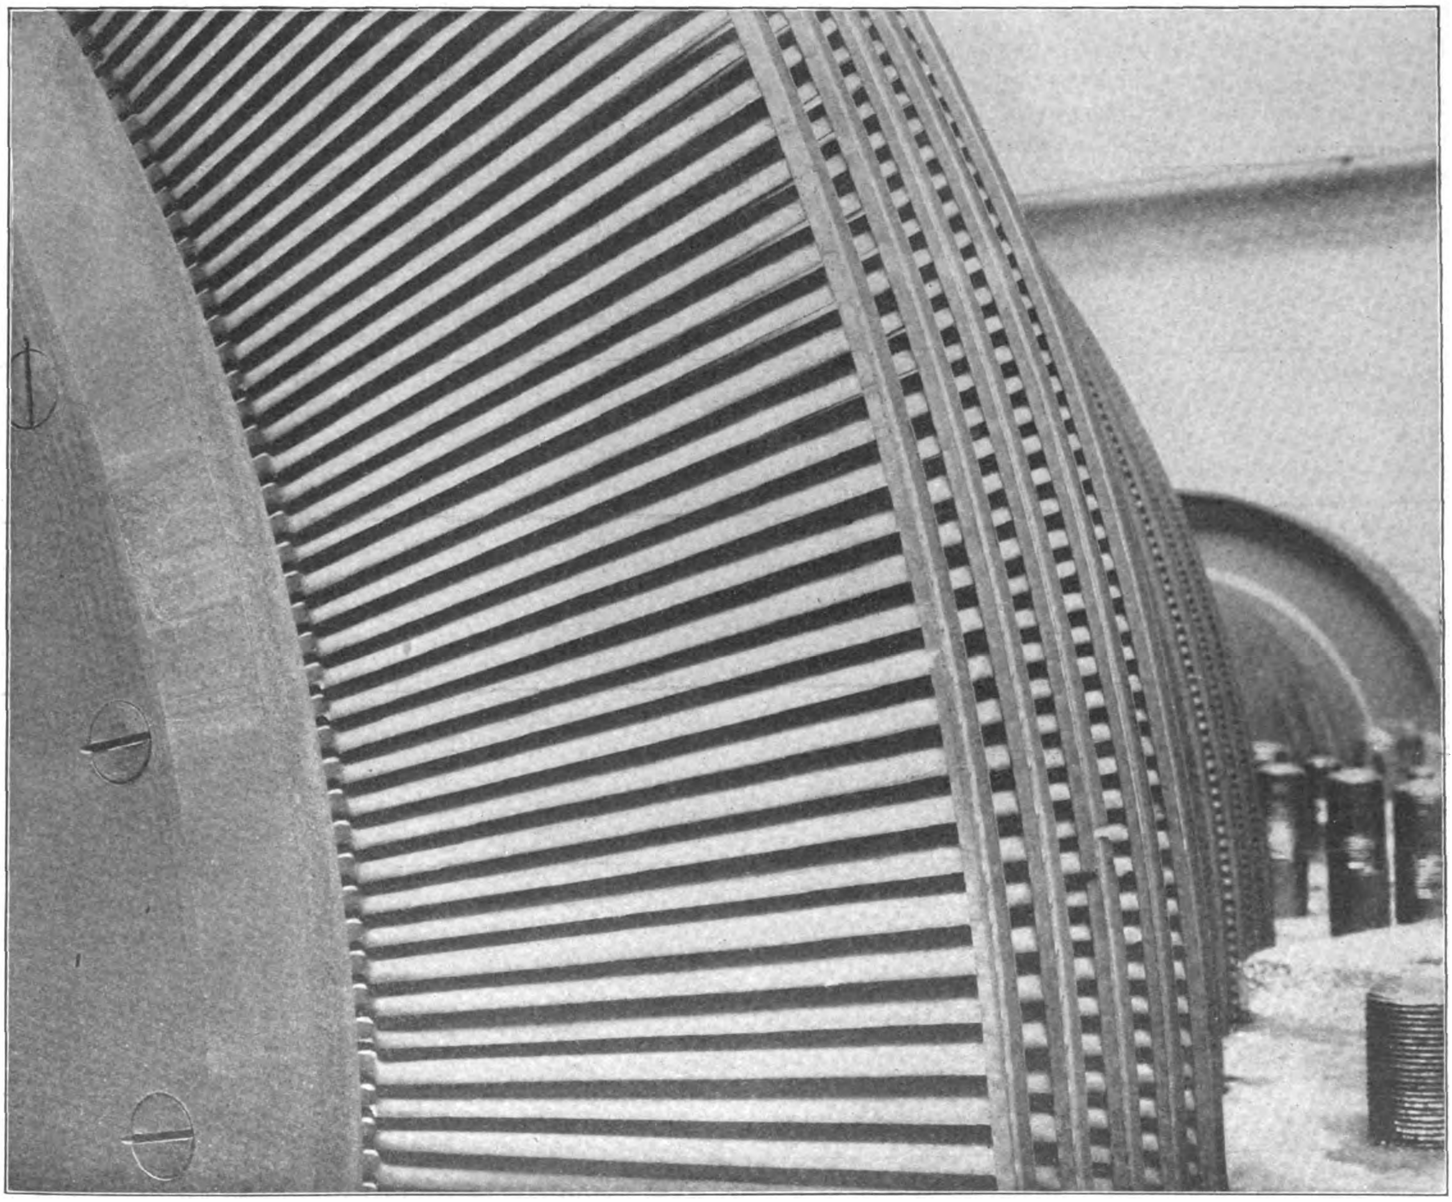




A 5,000-KILOWATT ALLIS-CHALMERS STEAM TURBINE AFTER TWENTY-SEVEN MONTHS' CONTINUOUS SERVICE IN THE POWER HOUSE OF THE BROOKLYN EDISON COMPANY, BROOKLYN, N. Y.

after twenty-seven months' continuous service. The camera was brought as close to the machinery as practicable, in order to secure the greatest detail possible. The photographic results show that there was absolutely no deterioration after this long period of service. Notwithstanding the high initial rating given the machine, it has frequently carried a load of 9,000 kilowatts for long periods continuously.

The constructional features of the Allis-Chalmers steam turbine are well known, and they will be referred to here only briefly. The turbine as manufactured today is the result of practical experience and systematic experiment extending over the period since 1884, when the first commercial "Parsons" turbine was produced. The turbine consists essentially of a fixed casing or cylinder and a revolving spindle or drum. The ends of the spindle are extended in the form of a shaft carried in two bearings, and excepting the small parts of the governing mechanism and the oil pump, these bearings are the only rubbing parts in the entire turbine. Steam enters through a main throttle or regulating valve, and passes into the cylinder at the high-prssure end, passing alternately through stationary and revolving rows of blades, finally emerging at the lowest stage and passing to the condenser or to the atmosphere. Each row of blades, stationary and revolving, extends completely around the turbine, the steam flowing through the full annulus between the spindle and the cylinder. The blades in each step are arranged in groups of increasing length. At the beginning of each of the larger steps the blades are usually shorter than at the end of the preceding smaller step, the change being made in such a way that the correct relation of blade length to spindle diameter is secured.



BLADING AND SHROUD RING OF 5,000-KILOWATT ALLIS-CHALMERS STEAM TURBINE AFTER TWENTY-SEVEN MONTHS' CONTINUOUS SERVICE IN THE POWER HOUSE OF THE BROOKLYN EDISON COMPANY, BROOKLYN, N. Y.

Each blade is individually formed by special machine tools, and the roots of the blades are held firmly in the foundation ring. To protect and, in a substantial manner, bind together the tips of the blades, a shroud ring is used. Holes are punched in this shroud ring to receive projections on the tips of the blades, these holes being accurately spaced by special machinery to match the slots in the foundation ring. The finished rings themselves are of dovetailed shape in cross-section, and are inserted in dovetailed grooves in the turbine cylinder and spindle, respectively, in which they are firmly held by key pieces. The latter, after being driven into place, are upset into under-cut grooves, positively locking the whole structure together and making it wholly impossible for a blade to get out of place.

The flanges of the channel-shaped shroud rings are made thin, so that in case of contact from any accidental cause, no dangerous heating will take place, nor will the rubbing rip out the blades.

SILICO-VANADIUM TRANSFORMER STEEL.

BY H. W. YOUNG.

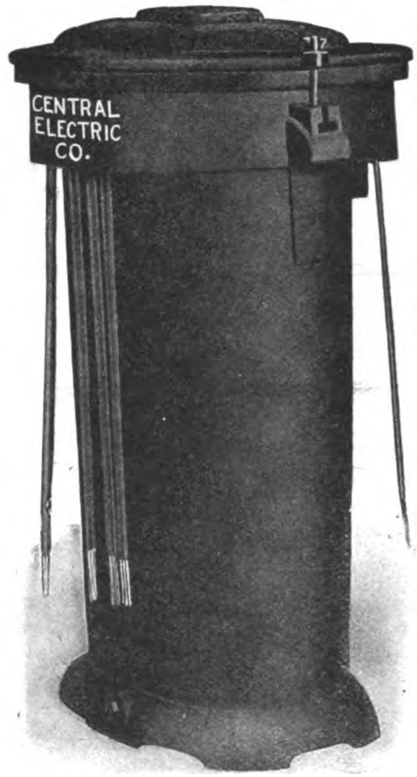
The remarkable magnetic qualities of the new silico-vanadium steel as used in recent designs of transformers has aroused so much inquiry that a brief discussion of the physical appearance of this alloy steel will be of interest.

Silico-vanadium steel is strongly crystalline in structure, looking very much like a sheet of zinc or tin, although the appearance of different samples will vary on account of the different thicknesses of scale arising from the annealing process. When held so that the light is reflected from its surface this crystalline structure is most pronounced. Occasionally, samples will be found which are coated with a dark blue scale covering the surface of the metal, but when this is removed the characteristic crystalline structure is plainly discernible.

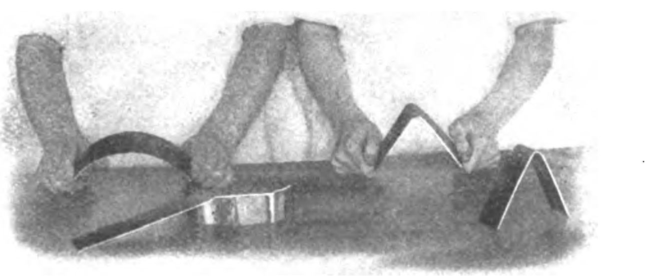
The susceptibility of silico-vanadium steel to oxidation during the annealing process is a very valuable commercial feature, for the reason that the exceedingly thin scale or film of oxide which forms on the surface is an insulator to the extent of rendering unnecessary the usual practice of painting or japanning the transformer laminations made from this steel. Insulating the laminations by paint or japan is not only expensive, but undesirable, for the reason that the japan or paint occupies some space, so that as much steel cannot be placed in a given section as would otherwise be employed.

In the accompanying illustration is shown a piece of silico-vanadium steel being bent into the form of a half circle, and also a piece of ordinary alloy steel, or silicon steel, which will not readily bend into the form of a half circle, but rather tends to form a V-shaped fold. The piece of silico-vanadium steel shown standing on edge has been bent sharply a number of times and shows how the dark blue scale has been loosened by the operation.

Anyone who is interested can thus readily compare the various alloy steels at present on the market by an examination of their physical appearance and also by the bending test, as shown in the illustration. A further peculiar characteristic of silico-vanadium steel is the manner in which it breaks and the appearance of the fracture. While there is a slight variation in the hardness of this steel, some pieces breaking instantly like glass upon the first attempt at bending, other samples may be bent very sharply several times before snapping. The fracture is irregular and the crystals may be easily seen without the aid of a magnifying glass.



COMPLETE SILICO-VANADIUM STEEL TRANSFORMER.



BENDING SILICO-VANADIUM STEEL.

As this subject is of such widespread interest at the present time, manufacturers have prepared small samples of the alloy steels which they are using, and are usually glad to send these on request.

The improved magnetic quality of silico-vanadium steel is now fully recognized as of great importance in decreasing transformer core losses, and improvements in efficiencies resulting are of material value to central stations. While the use of this new alloy has necessitated more or less redesigning the standard transformer, the general appearance has not been greatly changed, as will be noted from the illustration showing a complete transformer mounted in the case.

Texas Independent Telephone Convention.

Seventy-five representatives of Texas independent telephone companies attended the convention of the Texas Independent Telephone Association, held at Dallas, October 25 and 26. J. B. Earle of Waco, the retiring president of the association, delivered an interesting address in which he pointed out the benefits to be obtained by the members of the association through organized and concerted effort. C. A. Shock of Sherman, retiring secretary-treasurer, spoke of the value of a state association. The effect of anti-trust and anti-pass laws on telephone development was discussed by T. P. Stilwell of Lone Oak, who took the position that this character of legislation had encouraged telephone development in Texas. "Financing Telephone Properties" was the subject of a paper by W. A. Walker, president and general manager of the San Antonio Telephone Company. C. W. Emmer of Beaumont discussed the matter of "Relation of the Exchange Owner to the Supply Dealer and Manufacturer." Addresses were also delivered on the subjects: "How to Increase Income and Curtail Expenses," by E. M. Chamberlain of Greenville; "Rural Lines and Connections," by W. P. Johnson of Corsicana, and "Value of Tact in the Telephone Field," by Floyd R. Brown of Dallas.

The following officers were elected for the coming year: President, D. A. Walker of San Antonio; vice-presidents, E. M. Chamberlain of Greenville, R. A. Renfro of Hillsboro, and I. W. Parks of Giddings; secretary-treasurer, T. A. Gould of Ennis. D. A. Walker was elected delegate to the international convention, with J. B. Earle as alternate.

Current Electrical News

CONTINENTAL EUROPE.

BASEL, OCTOBER 17.—The city of Sofia, Bulgaria, whose population is estimated at 100,000, is well provided with electric lighting and tramways. To furnish the current for both purposes there have been erected two electric plants of some size. The first of these stations is a hydro-electric plant, about ten miles from the city, near the village of Pantcharevo, on the Isker River. The remainder of the power is supplied from a steam plant located within the city limits. The hydraulic plant uses a 170-foot head of water and has a capacity of about 1,600 kilowatts at present. Oerlikon alternators of the three-phase type are used in the station, and are direct-coupled to Piccard-Pictet wheels, manufactured at Geneva. In the second plant, within the city, are installed three units of 400 kilowatts each, arranged to be worked in parallel with the hydraulic plant, for both lighting and tramways. Owing to the extension of the tramway lines a new 1,000-horsepower group will be especially installed for this purpose. The lighting mains of the town are 3,400 volts on the primary and 150 volts on the secondary.

At the electrical exposition of Marseilles the section relating to traction contains some interesting electric railway exhibits. The Marseilles tramway company, which now operates one of the most extensive systems in Europe, shows a number of models of its city and suburban cars and motors. The Schneider Company of Creusot (France) has a complete exhibit of track material and rolling stock, together with many samples of fittings. Underground conduits for electric tramways are exhibited by the East Parisian Company. The Bordeaux Tramways Company has a large exhibit, which includes a train of three cars, two motor cars and a trailer, of the most recent type. A similar exhibit is made by the traction company of Nice, showing its multiple-unit cars. The Genoa company has two narrow-gauge traction cars, in which the electric outfit was furnished by the Allgemeine Elektrizitäts Gesellschaft of Berlin.

At Budweis, Austria, there is a project in consideration for a new system of narrow-gauge electric traction lines for the city. The International Electric Company is one of the promoters, and it is intended to run several different sections of line in the town and the suburbs. A new suburban tramway line, which was opened not long ago at Berlin, runs to the locality of Altstadt. Passengers and freight are carried on this line. The city of Basle, Switzerland, besides having extensive tramway lines within the town, is now the terminus of two suburban lines. One of these lines (the Birseck road) uses a type of motor car and trailer. The extensive electrical works of the Abott Company, one of the largest in Switzerland, are located on the present line at Münchenstein. The second suburban system, known as the Birgstal road, uses motor car trains.

At St. Petersburg not long since there was held a congress of the leading railroad officials of the county to discuss the question of adopting electric traction upon parts of the principal railroads of Russia. This move is an important one, as it is proposed to use the electric system upon the St. Petersburg-Moscow, Kharkoff-Sebastopol, St. Petersburg-Warsaw and Kieff-Odessa lines.

A. DE C.

GREAT BRITAIN.

LONDON, OCTOBER 16.—Just as there seemed to be a possibility of the London electric power bills being allowed to come before a committee of the House of Commons and being considered on their merits, the opposition of the London municipal authorities has assumed a most virulent form, and every effort is to be made to prevent the companies' bills going forward. Considerable strong feeling has been shown at the action of many members of Parliament for London assenting to the second reading of the bills, their reason being that they were convinced of the necessity for some bulk supply arrangements being made, and that as the London County Council had expressed its intention of not entering the field with a scheme, they voted for the companies' bills as the only alternative.

The delegates to the International Conference on Electrical Units and Standards are not lacking entertainment. Luncheons and dinners have been given by the government, and also by the Royal Society and the lord mayor of London, and visits are being made every day to numerous institutions, both scientific and popular.

Trolley omnibuses appear to be creating an impression among municipal tramway authorities. The latest giving consideration to their adoption are the Liverpool and Falmouth local authorities. Similarly, the London Electrobus Company continues to make applications to numerous provincial authorities for permission to run electric omnibuses in parts not touched by tramways.

Rumors are afloat in London of the formation of a new electric power company, with the sole object of supplying the Rand (South African) mines. Of interest in the same connection is the report of the Victoria Falls Power Company, which has just been issued. From this it is clear that the utilization of the waterpower at the Victoria Falls is not at all an immediate possibility. In fact, a new steam station is about completed, at Brakfran, while a second similar station at Germiston is under construction. The first has a capacity of 8,000 horsepower and the latter 16,000 horsepower.

G.

EASTERN CANADA.

OTTAWA, OCTOBER 24.—The new electric line, the Montreal & Southern Counties Railway, which some time ago secured an entrance into Montreal from the South Shore, has started construction work.

The proposal to lease the properties of the Mexican Light & Power Company to the Mexico Tramways Company meets with such adverse criticism from shareholders of the former company that the project has practically been shelved. Sir George Drummond's recent resignation from the presidency of this company is understood to have been by way of a protest against the sacrifice of its interests to the aggrandizement of the Tramways concern.

The Ontario Hydro-Electric Power Commission has announced that the engineers have adjusted the details of the construction of the Niagara Falls transmission lines with the contractors and work will commence at once.

In spite of the depression in business during the past year, the financial statement of the Montreal Street Railway shows that the road received an increase in gross and net earnings for the year ended September 30. The gross earnings are given at $3,677,432, and the operating expenses amounted to $2,158,394. The net income is placed at $1,136,411, and after dividend payments a surplus of $235,686 is left.

Much Canadian capital is invested in the West India Electric Company, which owns and operates the tram service at Kingston, Jamaica, James Hutchinson, of Montreal, being the president. This company operates about twenty-five miles of road, all of which is of first-class construction. The natives are employed as motormen and conductors and have been found fully competent for their respective duties.

W.

WESTERN CANADA.

WINNIPEG, OCTOBER 31.—Timely rains in Victoria, B. C., have put an end to the power famine in that city, and it is expected that there will be no more trouble before next summer, when it is intended that the British Columbia Electric Railroad Company will have a new power plant in operation. This company will erect a huge concrete dam at Coquitlam Lake, near New Westminster, B. C., for the purpose of increasing its power. This dam will be seventy-five feet high, ranging in width from forty feet at the base to the width of a wagon road at the apex.

The municipal electric street railway system at Edmonton, Alberta, was put in operation on October 26.

The city of Port Arthur, Ontario, has made a contract for the supply of 400 electrical horsepower, at $25 per horsepower, from the Kaministiquia Power Company of Fort William, Ont. The company will build a sub-station in Port Arthur, with a capacity of 2,000 horsepower, and will distribute power to manufacturing concerns in Port Arthur and Fort William.

The telephone line between South Pender and Pender Island, B. C., has been completed by the Dominion government, and arrangements are now being completed for the extension of the line to Mayne Island, giving through communication with Victoria, B. C. R.

IMPORTANT DEVELOPMENTS.

NEW PLANS FOR MOJAVE RIVER POWER SCHEME—A new company has been organized for the purpose of taking over the Westwater interests in the Victor dam project, and the great scheme of impounding the waters of the Mojave River by filling up the natural dam site at Victorville may soon be accomplished. The company has filed articles of incorporation under the name of the Mojave Water and Power Company, with an authorized capital of $2,000,000.

HUGE WATERPOWER DEVELOPMENT TO MANUFACTURE PAPER—The Minnesota & Ontario Power Company has been incorporated, with a capitalization of $7,000,000. The corporation plans to develop idle waterpower, establish a paper manufacturing center and conduct lumbering operations over a territory of 150,000 square miles. The board of directors is as follows: Edward W. Backus, William E. Brooks, Warrens Curtis, John A. Davis, of New York; W. A. S. Peabody, Alexander Smith, of Chicago, and Warren Curtis, Jr., formerly of Corinth, N. Y.

RECEIVERS FOR HUDSON RIVER COMPANIES—Receivers have been appointed for the Hudson River Electric Power Company, which was organized in 1903, and controls the Hudson River Water Power Company, Hudson River Electric Company, and Hudson River Power Transmission Company, together with various sub-companies owned by the last two named, supplying central and eastern New York state with power. The authorized capital stock was $10,000,000, of which $5,390,000 was issued. The total funded debt of the corporation, according to its last statement, was $9,683,500. Net earnings for 1907 were $486,200.

POWER DEVELOPMENTS AT NECAXA, MEX.—Contracts have been let by the Mexican Light and Power Company for the construction of the three tunnels and a canal to divert water to the reservoirs of the company at Necaxa. The tunnels will be, respectively, one of 1,400 meters and two of 350 meters in length, and the canal will be two or three kilometers in length. Two additional dams are to be built at Necaxa for the storage of this additional water supply. One of these dams will contain 800,000 cubic meters of material and the other 250,000 cubic meters. The power house at Nacaxa is also to be increased by two large concentrators, of 16,000 horsepower capacity. The Laguna reservoir dam has been completed and the reservoir is now about half full of water. This reservoir has a capacity of 44,000,000 cubic meters. The Los Reyes reservoir dam has also been completed and is practically full of water. This reservoir has a capacity of 12,000,000 cubic meters. Shareholders of the Mexican Light and Power Company will hold a special meeting in Montreal, Canada, on December 3, for the purpose of ratifying an increase of $3,800,000 in the preferred stock issue of that company.

PROMOTES $24,000,000 TROLLEYLESS STREET-RAILWAY SYSTEM FOR SAN FRANCISCO—John J. Egan, a promoter, concerning whom little appears to be known, is seeking a 25-year franchise in San Francisco for a street car system, to traverse 244 miles of streets, and to be established at an expenditure of $24,000,000. He says he has recently received a patent for a new type of electric street car system, the conductor rail being carried on the roof of the cars, projecting 25 feet ahead and the same distance behind. The ends are to touch poles set at regular intervals, thus keeping the car at all times connected with the source of current.

UNION TRACTION COMPANY, OF PHILADELPHIA, VOTES IN FAVOR OF $5,000,000 LOAN—Stockholders of the Union Traction Company, of Philadelphia, Pa., voted in favor of the $5,000,000 loan to the Philadelphia Rapid Transit Company, the holding company, 506,757 shares voting in favor and 3,435 against. After the announcement that the loan proposition was carried the following resigned: John B. Parsons, as president and director; George D. Widener, as vice-president and director; P. A. B. Widener, W. H. Shelmerdine, George H. Earle and J. J. Sullivan, as directors. E. A. Ballard then nominated the following, who were elected to the vacancies: John H. Chestnut, William P. Katz, Jacob S. Disston, Henry Fernberger, Edward M. Story and J. J. Sullivan. After the Union Traction meeting the stockholders of the Philadelphia Rapid Transit Company held a special meeting ratifying the Union Traction Company $5,000,000 loan.

INDEPENDENT INTERESTS PLAN NATIONAL LONG-DISTANCE SYSTEM—The reported combination of independent long-distance telephone interests to form a national long-distance system was confirmed at Buffalo, N. Y., on October 29, by B. G. Hubbell. "Contracts are now being closed," said Mr. Hubbell, "with twelve of the principal independent long-distance companies for the use of rights-of-way, poles and connections, and there is every prospect of early incorporation and the beginning of construction. The plan is to fill in the gaps between existing long-distance systems to form a single group, with Poughkeepsie, N. Y., as the eastern terminus, Kansas City as the western, and Mobile, Ala., as the southernmost point. Within this area will be united Chicago, Detroit and Michigan points, with Cleveland, Buffalo and Rochester to the east and St. Louis, Indianapolis, Louisville, Pittsburg, Scranton and Philadelphia, besides intermediate points."

PROPOSALS.

VACUUM CLEANING SYSTEM FOR FEDERAL BUILDING, CLEVELAND—The office of the supervising architect will receive sealed proposals until November 21 for the installation of a vacuum-cleaning system for the Federal building at Cleveland, Ohio, in accordance with specifications, which may be had at the above office or the office of the architect, Arnold W. Brunner, 33 Union square, West, New York city.

POSTOFFICE, GAINESVILLE, GA.—The office of the supervising architect, Treasury Department, Washington, D. C., will receive sealed proposals until December 8 for the construction (complete) of the U. S. postoffice at Gainesville, Ga., in accordance with the drawings and specifications, copies of which may be had at the above office or at the office of the postmaster at Gainesville.

ENGINEERING SOCIETIES.

BOSTON BRANCH, A. I. E. E.—The first monthly meeting of the Boston section of the American Institute of Electrical Engineers was addressed by Professor Charles M. Allen, of the Worcester Polytechnic Institute, on the subject, "Testing by Dynamometers."

WORCESTER POLYTECHNIC BRANCH, A. I. E. E.—The meeting of the Worchester Polytechnic Branch of the Institute, at Worcester, was given over to a discussion of the proceedings of the American Street and Interurban Railway convention at Atlantic City last month.

ELECTRIC LIGHTING.

TOPEKA, KAN.—The Great Bend Water & Electrical Company, with a capital stock of $80,000, has been granted a charter.

NASHVILLE, TENN.—The Tennessee Electric Company has been incorporated for $5,000 by I. L. Canoway, J. H. Rudisell and T. S. Sinson.

ANTLERS, OKLA.—An engineer has been employed to make estimates of cost of an electric-light plant which the city contemplates installing.

STOCKBRIDGE, MASS.—The Stockbridge Lighting Company seeks authority to issue $15,000 additional capital stock, making the total $40,000.

ALBANY, KY.—Five citizens have formed a stock company and Albany is to have an electric light plant. The plant will be installed at once.

BASTROP, TEX.—T. A. Orgain, city secretary, has charge of a project for the city to issue bonds for the purchase of an electric-light plant.

SPOONER, MINN.—Building on the Shevlin-Mathieu power house has been commenced. The structure throughout will be of concrete and steel.

BUFFALO, N. Y.—The Republic Electric Company has been incorporated for $5,000 by a number of incorporators, headed by William E. Robertson of Buffalo.

WARREN, OHIO—Mayor Kilpatrick has vetoed the ordinance passed in council in favor of the Hydro Electric Company and the Warren Water & Light Company.

STOYESTOWN, PA.—The Stoyestown Light, Heat & Power Company is to be organized, with a capital stock of $7,500. D. E. Long heads the list of incorporators.

COLUMBUS, OHIO—The East End Electric Company of Cleveland has been incorporated with a capital stock of $10,000. C. R. Foster heads the stockholders.

ROOSEVELT, N. Y.—The Roosevelt Waterpower and Light Company has been incorporated, with a capital stock of $40,000. Edward Uhe heads the incorporators.

MONTGOMERY, ALA.—The Choctawhatchie River Light and Power Company has been incorporated for $1,000,000, of which $500,000 is paid in. W. C. Fritter heads the incorporators.

SCHENECTADY, N. Y.—According to newspaper reports the Schenectady Illuminating Company is to erect an eight-story building at State and Barrett streets, on the site of the Park House.

JACKSONVILLE, FLA.—An ordinance before the city council provides for granting a franchise for an electric light and street railway system to M. M. Smith, W. D. Holden and A. Johnson.

HARRISBURG, PA.—Plans for a permanent decorative illumination of Market street and Market square have been made by the Harrisburg Light, Heat and Power Company. Several blocks are now thus illuminated.

FAIRFIELD, CONN.—A report on the cost of installing an electric lighting plant to light the villages of Fairfield and Southport, made at a meeting of the Fairfield Village Improvement Society, is now before the people of the town.

ELWOOD, IND.—The plant of the Citizens' Heat and Light Company, of Elwood, was sold at receiver's sale at the Anderson courthouse for $50,000, the purchase being made by E. R. Ester, a member of a committee representing the stockholders. The plant was appraised at $375,000. The Central Indiana Electric Company is expected to take over the Elwood plant as soon as it secures a franchise in Elwood. The bonded indebtedness of the Elwood company is $364,000.

FRANKFORT, IND.—The municipal electric light plant was wrecked October 27, sustaining $25,000 damage, by the explosion of a fourteen-ton flywheel. The governor on the 500-horsepower engine stuck, it is said, and pieces of the flywheel were hurled 300 feet.

ATLANTIC CITY, N. J.—Chairman Donnelly, of the council's lighting committee, has been authorized to secure bids for the lighting and illumination of the "boardwalk" next year. The present contract expires in a few weeks. Bids are to be received until November 9.

CARL JUNCTION, KAN.—Business men are urging a lighting system from the lines of the Joplin-Pittsburg Electric Railway, which passes through Carl Junction. It is understood that the company can furnish all power necessary and would wire the city at a reasonable rate.

BUENA VISTA, VA.—The Rockbridge Power Company has secured a franchise to furnish the city with electric light and power. The company proposes to develop waterpower on North River and furnish electricity to Buena Vista, Glasgow, Buchanan and possibly Lexington, Va., locating sub-stations in each city.

PLATTEVILLE, WIS.—O. M. Fox and M. F. Fox are considering extending electric light and power lines to Platteville, having already decided to build from Galena to Benton and Cuba City. The company which they head is erecting an electric power plant at Galena, to furnish light and power to the vicinity.

NAPA, CAL.—The board of supervisors has granted E. D. Lehe of Dixon a franchise to construct electric power lines over the roads of Napa County north from the city to the Lake County line, passing through St. Helena and Calistoga. Mr. Lehe plans to re-establish the electric lighting system at Calistoga.

BEDFORD CITY, VA.—A 1,000-horsepower hydro-electric plant is planned for a power site on the James River, 25 miles from Bedford City. There is a fall of seventeen feet at this point, and it is estimated that the present dam will generate 1,200 horsepower. The power would be transmitted and used to light the city.

LINDSAY, OKLA.—The board of trustees has called for an election on the proposal to appropriate $40,000 for a water and electric light system for Lindsay. The town is situated in a prosperous and growing country and apparently there is little opposition to the movement, and it is predicted that the election will carry by a large majority.

CHICAGO, ILL.—The Commonwealth Edison Company has obtained control of the property at the southeast corner of Quarry street and the Chicago River through a lease from Northwestern University. The tract contains 118,356 square feet, or almost three acres. The present lease is for ninety-five years from November 1 of the present year, the total rental being $308,750.

ST. LOUIS, MO.—Property owners of the district bounded by Fourth, Twelfth, Washington and Market streets, are discussing a uniform system of lighting for the downtown streets. A committee has presented figures on the cost of carrying out the plan in the district named, and interesting data from other cities, which have adopted the electrolier system, were furnished the property owners.

TERRE HAUTE, IND.—The directors of the Pleasant Shades Power Company, which was incorporated under the laws of Indiana September 1, for $100,000, have decided to locate the home offices in Terre Haute. M. H. Ewers, president of the company, heads the list of Terre Haute men who comprise the incorporators. The new company was organized to build a waterpower generating station and summer resort on Rocky River, or Sugar Creek, near Waveland, thirty-two miles from Terre Haute. The company owns about 400 acres of land. A dam 350 feet long and twenty feet high will be built to supply waterpower for generating 500 kilowatts of electric power, to be used in lighting the resort and operating an electric railway.

PROVIDENCE, R. I.—The stockholders of the Narragansett Electric Company will shortly be called upon to consider the advisability of an issue of $500,000 in 4 per cent debentures. The purpose of the issue is to retire a portion of the floating indebtedness of the company. This issue, if approved by the stockholders, will make the total of outstanding securities of the company of all classes $4,500,000.

BLUE ISLAND, ILL.—The Sanitary District of Chicago has entered into a contract to supply the town of Blue Island with light and power. Compensation was fixed on a basis of estimated returns to the District of $14,000 the first year and increases each year thereafter. The District is to take over the commercial lighting system and supply current to the residents of the town at a rate of 10 cents per kilowatt hour.

PUGET SOUND, WASH.—Work is progressing on the construction of the new $450,000 central power plant, which is being built at the Navy Yard. The Westinghouse Electric and Manufacturing Company has secured the contract for supplying a 1,000-kilowatt generator and a 500-kilowatt generator. These, in addition to the 500-kilowatt generator previously contracted for, will give the plant a generating capacity of 2,000 kilowatts.

CHATTANOOGA, TENN.—The Chattanooga-Tennessee River Power Company awarded a contract to Guild & Company of Chattanooga, to furnish material and construct a transmission line fifteen miles long from Hale's Bar to Chattanooga. Steel towers resting on concrete foundations will be erected along the right-of-way. The contract involves the expenditure of about $150,000. The company is constructing a hydro-electric plant at Hales Bar to secure an ultimate development of 56,000 horsepower.

OBITUARIES.

MR. HENRY A. BUTTERS, president of the Northern Electric Railway Company, died in Berkeley, Cal., last week. He was widely known as a mining man and capitalist.

DR. DANIEL C. GILMAN, first president of the Johns Hopkins University, Baltimore, Md., and afterward head of the Carnegie Institute, Washington, died on October 14 at Norwich, Ct., at seventy-seven years of age. Educated first at Yale and then at Cambridge and Berlin, he became president of the University of California in 1872. Five years later he went in the same capacity to the Johns Hopkins University. His work there, which lasted until 1901, secured him a place among the foremost American educators. In 1891 Dr. Gilman left Baltimore for Washington, where he spent three years organizing the Carnegie Institute. In addition to the work of his various university appointments, Dr. Gilman was appointed by President Cleveland to act as commissioner in the Venezuela and British Guiana boundary dispute. He was president of the American Oriental Society, and a prominent member of various learned societies and institutions.

NEW PUBLICATIONS.

NATIONAL BOARD OF FIRE UNDERWRITERS—Among recent publications of the National Board of Fire Underwriters are two leaflets giving rules and requirements for the construction, installation and use of coal gas producers on both the pressure and suction system, and rules for the construction and installation of incubators and brooders. Devices heated by coal, gas or electricity are regarded as much less hazardous than those heated by oil flames.

THE ARMOUR ENGINEER—During the coming year there will be published Volume I of the Armour Engineer, the new semi-annual technical publication of the student body of the Armour Institute of Technology, Chicago. This is an engineering magazine issuing two large numbers each year, one for each semester. The Armour Engineer is to contain technical articles by prominent Armour graduates, results of research in the Armour testing laboratories, the best papers presented before the engineering societies, editorials, book reviews, engineering notes and comments.

TELEPHONE AND TELEGRAPH.

WILKES-BARRE, PA.—The Bell Telephone Company has been given permission to start the work of laying its wires in the central part of the city under ground.

SPOTTSYLVANIA, PA.—The Caroline Telephone Company is extending its line to the town of Bagby, in that county, and will run it from there to Port Royal, on the Rappahannock River.

NASHVILLE, TENN.—The Limestone Telephone Company has been incorporated to operate in Washington County, with a capital stock of $3,000. S. B. Moreloch heads the incorporators.

READING, PA.—The Mt. Zion Rural Telephone Company has been organized by farmers and business men of Mt. Zion. The line will cover a territory of twenty miles, including Mt. Ætna, Frystown and Lebanon.

BIRD ISLAND, MINN.—The village council has granted a franchise to A. C. Bowe, of Merriam Park, for the installation of a telephone system. Mr. Bowe will put in a modern plant, using the common battery system.

GROTON, VT.—The Groton Telephone Company has been organized, with a capital stock of $10,000, for the purpose of maintaining telephone lines in the towns of Groton, Bradford, Topsham, Barnet, Corinth, Newbury, Peacham and Ryegate.

BOYDS, MD.—The Boyd Telephone Company, supplying Montgomery, Frederick and Carroll counties, later controlled by the American Union Company, has been sold, with all franchises, to the recently organized Montgomery Telephone Company, which plans to build an independent line, with metallic circuit.

CORDOVA, ALASKA—Mummy Island, about eight miles from Cordova, has been selected as the site for the navy wireless station, to be established on the Alaskan coast to close communication between the coastal wireless station of the navy and the military Alaskan telegraph system. Work on the new station already has begun.

NEW BRUNSWICK, N. J.—The Middlesex Telephone Company, of Monmouth Junction, is capitalized at $10,000, of which $1,000 is subscribed. The incorporators are: Clarence S. Groves, of Dayton; D. C. Mershon, Prospect Plains; Andrew Ely, Dayton; A. V. Stout, Monmouth Junction; W. J. Rowland, Monmouth Junction; George W. Waite, Deans.

BOYDS, MD.—A meeting attended by residents of Poolesville, Dickersons, Boyds, Dawsonville, Barnesville and other points was held at Poolesville recently for the purpose of organizing a telephone company. A metallic system will be installed. Howard G. Spurrier, of Poolesville, was elected president of the company, A. D. Trundle vice-president and Reginald J. Darby secretary-treasurer.

PHILADELPHIA, PA.—The Keystone Telephone Company has taken no action upon the proposed plan to form the Keystone and other independent telephone companies into a concern to handle long-distance telephone and telegraph business all over the country. It is stated, however, that the new company will be incorporated with a capitalization of between $10,000,000 and $20,000,000.

DELHI, LA.—The West Carroll Telephone and Improvement Company has been formed, with a capital of $10,000, to build and maintain a telephone system covering the territory embracing Richland parish and other parts of the state. It will be a subsidiary of the Cumberland Telephone and Telegraph Company. The president is W. B. Redmond. Local exchanges will be maintained at Delhi, Floyd, Kilborn, Calvert and Pioneer.

HARRISBURG, PA.—The Bear Gap & Numidia Telephone Company, the line of which touches towns in Northumberland, Columbia, Mountour and Schuylkill counties, has been incorporated with a capital stock of $5,000. Adam W. Dimmick, of Paxinos, is treasurer. Lavelle Telephone and Telegraph Company, touching towns in Schuylkill, Columbia and Northumberland counties, has been incorporated for $5,000; H. O. Lenker, Lavelle, is treasurer.

PERSONAL MENTION.

MR. PAUL W. HORBACH will succeed Mr. E. J. Sullivan as manager of the Nebraska Electrical Company at Omaha, Neb., of which he is president.

M. HENRI POINCARE has succeeded the late Henri Becquerel as president of the French technical commission on radiotelegraphy appointed March 5, 1907.

MR. BION J. ARNOLD of Chicago has been elected an honorary member of the engineering fraternity, Tau Beta Pi. He was initiated into this honorary society on October 30.

MR. C. O. BAKER, of New York city, the head of the well-known platinum house of Baker & Company, who had been dangerously ill for six weeks past, is again in good health and active service.

MR. MARK LOUD of Dallas, Tex., who is associated with Stone & Webster, was a New York visitor last week. While in the city he was tendered a luncheon at the Machinery Club by Capt. Willard L. Candee.

MR. L. H. VAN ALLEN, at one time general superintendent of the New York Central, has been appointed general manager of the Buffalo, Genesee & Rochester Traction Company, with headquarters in Buffalo, N. Y.

MR. E. W. GOLDSCHMIDT, New York manager of the Wagner Electric Manufacturing Company, was to sail November 6 on the White Star liner Cretic for Naples, expecting to remain abroad until the first of the year.

MR. JAMES RAYMOND DEANE was married on October 15 to Miss Cornelia Mercedes Donovan at St. Vincent's Church, Chicago, the Rev. P. V. Byrne officiating. Mr. Deane is associated with the Guarantee Electric Company.

MR. GEORGE R. DENEHIE, formerly of the Tampa Electric Company, Tampa, Fla., will succeed George F. Morse as master mechanic of the Terre Haute, Indianapolis & Eastern Traction Company at Terre Haute, Ind. Mr. Morse becomes master mechanic of the Tampa Electric Company.

DR. A. RAPP and MESSRS. G. GRABBE, C. F. BAUMANN and S. HEISEY of Berlin, Germany, are visiting automatic telephone plants throughout the country on a trip of inspection, escorted by Dr. Frank of New York and Dr. Sulsberger and Messrs. W. E. Cook and Russell of Chicago. The party has visited the automatic plants at Columbus, O., and Grand Rapids, Mich.

DR. JOHN W. HAYFORD, member of the international boundary commission of the United States and Mexico, and well-known as an engineer, has been appointed dean of the new school of engineering of Northwestern University, Evanston, Ill., and will take up his duties September 1, 1909. The new dean is a graduate of Cornell University, class of 1889, and is 40 years of age.

MR. ARTHUR WILLIAMS, recently made president and general manager of the Union Electric Light & Power Company of St. Louis, has resigned this position, which he had occupied but two months, succeeding Mr. V. N. Powelson. Mr. Williams went to St. Louis from the New York Edison Company, where he had built up a unique position as general inspector. It is rumored that Mr. Richard McCulloch of St. Louis will succeed Mr. Williams as the local executive head of the Union Electric Light and Power Company.

MR. VAN RENSSELAER LANSINGH, illuminating engineer, of New York, delivered an address before the electrical section of the Canadian Civil Engineers' Society at Montreal, October 22, emphasizing the necessity of engineers and architects working together to secure proper natural and artificial lighting of buildings. On November 5 a similar address was delivered before the Dayton (Ohio) Electrical Club, including representatives and engineers of the Dayton Lighting Company, local electrical contractors and jobbers, and a number of the owners and managers of large buildings.

MR. G. HENNING YOUNGREN, for some time past western advertising manager of the Manhattan Electrical Supply Company, will engage in the preparation of technical copy for advertisers and institute follow-up systems and publicity campaigns, particularly among the members of the electrical industry. Mr. Youngren's headquarters are at 630 North Humphrey avenue, Oak Park, Ill.

MR. HERBERT H. EVANS, of Chicago, a collaborator on the report of electrification of railway terminals and the Illinois Central, made under the auspices of the committee on local trans portation, city council, has received an appointment as secretary of the committee, a position created by the council in view of the volume of important business to be considered during the next two years. Mr. Evans is a mechanical engineer and a brother of Dr. W. A. Evans, city health commissioner, a joint author of the electrification report with Alderman Foreman and Messrs. Paul P. Bird and Gilbert E. Ryder, of the city smoke inspection department.

ELECTRICAL SECURITIES.

Last week was marking time in the stock markets generally, biding the result of the election. The very obvious improvement steadily going on in business conditions all over the country has discounted to a considerable degree the apprehension which has been felt as to the turn affairs might take in national politics. Some convincing signs of betterment are seen in the reports of increased earnings of railroads, particularly those roads operating in western territory. The statement of the United States Steel Corporation of its September quarter's earnings is also very favorable. The gross traffic returns for the month of September of the Rock Island system, the Omaha, and the Minneapolis & St. Louis, were all above those of September, 1907. The Union Pacific gained $464,000, and the Northern Pacific $209,000. Eastern roads, while failing to show the same improvement, are recovering slowly.

ELECTRICAL SECURITIES FOR THE WEEK ENDED OCTOBER 31.

New York:	*Closing.*
Allis-Chalmers common	11⅝
Allis-Chalmers preferred	39½
Brooklyn Rapid Transit	48¼

NEW MANUFACTURING COMPANIES.

THE AMERICAN ELECTRICAL MANUFACTURING COMPANY, Orange, N. J., has been incorporated, with a capital stock of $350,000. John C. Ireland, Everett Frohman and T. Wesley Wright are the incorporators. The company will manufacture electrical and mechanical goods.

ELECTRIC RAILWAYS.

SUSQUEHANNA, PA.—A new interurban line is projected between Factoryville and Susquehanna.

PITTSBURG, PA.—Pay-as-you-enter cars have been put into service on the principal lines of the Pittsburg Railways Company.

DETROIT, MICH.—The Detroit United Railways Company has put into service a handsome new funeral car which cost $8,000.

WHEELING, W. VA.—The Union Traction Company's line now operating between Sistersville and New Martinsville will be extended to Hannibal.

GLEN ROSE, TEX.—J. Mercer Carter, who is engaged in promoting an interurban road into Glen Rose, announces that $50,000 worth of stock has been subscribed.

WILMINGTON, DEL.—The Wilmington & West Chester Electric railway has secured its right-of-way through Delaware and the greater part of the Pennsylvania section.

EUGENE, ORE.—The Mackenzie River Power & Railway Company, which is incorporated with a capital stock of $100,000, plans an electric road from Eugene to Belknap.

NORTH FORK, W. VA.—Capital has been secured for building an electric road from North Fork to Elkhorn, a distance of four miles. Work is to commence as soon as a franchise is secured.

JOLIET, ILL.—The Joliet & Southern Traction Company has begun running its cars on the New Lenox line. When the line from Joliet to Chicago Heights is completed, a half-hour schedule will be inaugurated.

WINONA LAKE, IND.—$300,000 will be expended by the Winona Interurban Railway Company to rush completion of the Warsaw-Peru division, giving through service from Benton Harbor, Mich., to Louisville, Ky.

LOWELL, MASS.—The Lowell, Acton & Maynard Street Railway Company has applied to the State Railroad Commission for permission to increase its capital stock by $25,000 at par, the amount to be used for extensions.

PUEBLO, COLO.—The Kansas-Colorado Railroad is in possession of the entire right-of-way from Turkey creek to the city limits and will ask the council for privileges on the city streets, promising that cars will be running within a year.

LA CROSSE, WIS.—Officers of the Sparta-Melrose Electric Railroad Company expect to begin operations in 1909 on the construction of a line between those two cities via Cataract, Angelo and Trout Falls, the road to be twenty-eight miles long.

NEW YORK, N. Y.—The New York & Queens Railroad Company has been granted by the Board of Estimate and Apportionment the franchise which has been pending for some time to construct extensions of its lines to Whitestone and Bayside.

JACKSON, MICH.—Work on the Jackson-Lansing electric line of the Michigan United Railways is to be rushed to completion, the contract for construction having been let to A. L. Drum & Company of Chicago. Cars are promised to be running by March of next year.

ALLENTOWN, PA.—The service of the Electric Express Company over the lines of the Lehigh Valley Transit Company has proved successful beyond all expectations. Goods are carried directly to the doors of farmers along the route, and the service is to be extended.

MODESTO, CAL.—The surveying corps of the Stockton-Modesto trolley line reached Modesto, having completed the survey between the two cities. Applications for franchises in both Modesto and Stockton will be made this week, and construction work will begin within a month. Private right-of-way has been obtained for the entire distance between the two cities, and the promoters expect to have the road finished by next July. It will later be extended to Turlock and other points down the valley, giving the producer direct communication with tidewater at Stockton.

EL PASO, TEX.—The organization of the El Paso & Fort Hancock Railroad Company has been projected. Charles N. Bassett is president of the company. The capital stock defined in the charter to be applied for is $100,000. The road will be built from El Paso to Fabens and later to Ft. Hancock.

PIERRE, S. D.—Articles of incorporation have been filed for the Dakota Southern Railway Company, with headquarters at Lemmon, S. D. It is organized by local men and proposes to construct a line from Rapid City to Williston, N. D., by way of Lemmon, and, as set forth, is capitalized at $90,000,000.

SEATTLE, WASH.—The Seattle & Issaquah Electric Railway Company has been chartered, with a capital stock of $2,000,000, by Edwin S. Gill and John McQuade, with the purpose to acquire, construct, equip, lease, own and operate steam or electric roads between points in King and Snohomish counties.

EVANSVILLE, IND.—Directors of the Evansville & Southern Indiana Railway Company, which includes interurban lines from Princeton to Evansville and the Evansville street railway system, have voted to extend the line, which will eventually connect Evansville and Terre Haute, northward from Patoka in the early spring.

AUGUSTA, GA.—An electric trolley line is projected from Augusta to Edgefield, one of South Carolina's most historic county seats. A contract for the survey work has been awarded, and prospects seem good for completion of the road within a short time.

GARY, IND.—A new interurban road, to be known as the Valparaiso, Hobart & Gary railway, is said to have the support of ample capital and to be built as soon as certain franchises are obtained. Among those interested is James Hopkins, son of Senator Hopkins of Illinois.

UVALDE, TEX.—The driving of the first spike in the Uvalde city railway lines was performed with much ceremony on October 20. Mayor Mat Burney of Uvalde and Mayor W. L. Rawlinson of Sansom wielded the hammers. M. M. McFarlane, who is the promoter of the enterprise, says the line will be in operation by December 1.

LEAVENWORTH, KAN.—In preparing to operate trains by electricity through the Cascade tunnel, the Great Northern Railroad is building a low concrete dam in the Wenatchee River, together with 11,000 lineal feet of nine-foot wooden flume and 1,000 feet of steel flume, to convey water to its power house. It is expected that the plant will be in operation by January 1.

ALTOONA, PA.—An electric trolley line from Altoona to Bedford Springs, by way of Morrison's Cove, has been definitely planned. The road will be fifty miles in length and will pass through Duncansville, Hollidaysburg, Roaring Spring, Martinsburg, New Enterprise and Woodbury. The estimated cost of the construction of the road, power plants and rolling stock is $1,500,000.

WEST NEWTON, PA.—Work will start next week on rival street railway lines between West Newton and Herminie, ultimately to be extended to form a short-cut line between the Youghiogheny and Monongahela valleys. The Jeannette, West Newton and Monongahela Valley Street Railway Company is placing grade stakes on its route, and the Pittsburgh & Westmoreland Company has a line partly constructed through the town and work will be resumed next week.

BUFFALO, N. Y.—A report favorable to the Buffalo & Lackawanna Traction Company has been filed by Michael Danahy, Michael F. Schelling and William B. Cutter, the commission appointed by the Appellate Division. The Buffalo & Lackawanna is in reality the Buffalo & Lake Erie Traction Company. The commission found that the route is the shortest possible between West Seneca and the business heart of Buffalo and that the distance can be traveled in thirty minutes less time than by the present route of the International Railway.

WASHINGTON, D. C.—Plans are being matured for the construction of a second trolley line between Washington and Baltimore. The plan is to close the gap between Ellicott City, Md., and Sligo, by the construction of new tracks, making use of the trackage of the Washington Railway & Electric Company, on the Brightwood line, and the Seventh street line of the Capital Traction Company for entrance to the district, and the tracks of the United Railways of Baltimore over the Ellicott City branch for entrance to Baltimore.

DATES AHEAD.

Association of Car-Lighting Engineers. First annual meeting, Chicago, Ill., November 18.

National Society for the Promotion of Industrial Education. Annual meeting, Atlanta, Ga., November 19-21.

International Independent Telephone Association. Annual convention, Chicago, Ill., December 1-3.

American Society of Mechanical Engineers. Annual meeting, New York city, December 1-4.

American Roentgen Ray Society. Annual meeting, New York city, December 28-30.

Chicago Electrical Show. Coliseum, Chicago, Ill., January 16-30, 1909.

American Association for the Advancement of Science. Annual meeting, Baltimore, Md., January, 1909.

Northwestern Electrical Association. Annual meeting, Milwaukee, Wis., January, 1909.

INDUSTRIAL ITEMS.

THE WESTERN ELECTRIC COMPANY, Chicago, in booklet No. 1150, explains the advantages of lead-covered telephone cable for aerial and underground purposes. Several pages of general instructive matter on the subject of cables are followed by a detailed description of the cable products of the company.

THE UNDERWRITERS' LABORATORIES, INCORPORATED, 382 East Ohio street, Chicago, has issued a thirty-six-page booklet descriptive of the nature of its work and the terms and conditions under which it conducts tests of fire-resisting appliances and materials. The laboratories are under the control of the National Board of Fire Underwriters.

ROSSITER, MACGOVERN & COMPANY, dealers in electrical machinery, Whitehall Building, 17 Battery place, New York city, have purchased the Charles E. Dustin Company, dealer in electrical, steam and miscellaneous machinery, formerly at 11 Broadway, New York city, and the offices of the latter company have been moved to those of the former.

THE EXCELLO ARC LAMP COMPANY, New York and Chicago, has published a new catalogue describing the Excello flaming arc lamp and its advantages for various kinds of lighting and giving full data on the various types of this lamp made. In a pamphlet entitled "Seen Everywhere" the company gives nearly thirty views showing installations of Excello lamps.

THE BAY STATE INSULATED WIRE AND CABLE COMPANY, Hyde Park, Mass., announces that it has no further business connection with the Western Wire Sales Company of Chicago, Ill., as the latter company has ceased to be its agent. Hereafter Mr. Richard Wick, 356 Dearborn street, Chicago, will represent the Bay State Insulated Wire and Cable Company in the Chicago district.

THE WARD LEONARD ELECTRIC COMPANY, Bronxville, N. Y., has issued a new bulletin relating to Ward Leonard load boxes, a loading device for replacing lamp banks. Different capacities are made, from 10 amperes to 23½ amperes on 120-volt circuits, and from 5 to 12 amperes on 240-volt circuits. A combination or double-voltage rheostat giving 24 amperes on 110 volts and 12 amperes on 220 volts, is listed. The bulletin declares that many of these rheostats are in daily use by the leading electric light companies of America, among the more prominent users being the Edison companies of New York, Detroit, Chicago and Brooklyn, and the Public Service Corporation of New Jersey.

THE CENTRAL ELECTRIC COMPANY, Chicago, has completed arrangements to sell and carry a Chicago stock of Ward Leonard meter-testing rheostats. A catalogue will shortly be issued describing these rheostats, together with full illustrations indicating the methods of applying them to testing of commercial meters of both alternating-current and direct-current circuits. A copy of this catalogue will be sent upon request.

THE HOLOPHANE COMPANY, New York, has published bulletin No. 11, devoted to high-efficiency reflectors. These have been particularly designed for use with Gem, tantalum and tungsten lamps, and are built on the new equal prism principle. The reflectors are made in three different types, extensive, intensive and focusing. In the bulletin there is also included a mass of data valuable in designing illumination with the new reflectors.

DOSSERT & COMPANY, 242 West Forty-first street, New York, reports the receipt of the following orders during the current week: 350 cable taps for feeder cable, from the Chicago City Railway Company; 1,750 two-ways, three-ways and fuse box plugs from the Edison Electric Illuminating Company of Brooklyn, and 800 connectors of various sizes and styles from the Western Electric Company of New York, for export to South Africa and the Klondike.

THE L. E. KNOTT APPARATUS COMPANY AND THE ARTHUR W. HALL SCIENTIFIC COMPANY announce that they will combine their respective assets and business experience, with a view to rendering the best possible service. Arthur W. Hall is to be actively connected with the new management. E. Cate, after more than a year's absence, partly abroad, resumes his connection. L. E. Knott retires. The business address continues to be 16 Harcourt street, Boston, Mass.

THE FOOS GAS ENGINE COMPANY, Springfield, O., announces that the United Cigarette Machine Company, of Lynchburg, Va., which has used several Foos engines in its power plant for eight or ten years, has recently placed an order for one of the Foos Company's 100-horsepower, multiple-cylinder vertical engines and producer gas plants complete. The engine will be direct connected to a General Electric generator, which is to supply current for the operation of the new plant nearing completion.

THE RAIL JOINT COMPANY, Troy, N. Y., at the annual meeting of its stockholders, held on October 28, chose directors as follows: George G. Frelinghuysen, Frederick T. Fearey, E. Y. Weber, C. P. Wheeler, Mark T. Cox, Marcus L. Ward, F. C. Runyon, L. F. Braine, Percy Holbrook, Benjamin Y. Wolhaupter and George A. Weber. The directors of the company organized with these officers: Chairman of the board, George G. Frelinghuysen; president, Frederick T. Fearey; vice-presidents, L. F. Braine and Percy Holbrook; secretary, Benjamin Y. Wolhaupter; treasurer, F. C. Runyon.

THE BENJAMIN ELECTRIC MANUFACTURING COMPANY, Chicago, has issued a handsome catalogue, B-18, describing and listing Benjamin wireless clusters and lighting specialties. Conveniently indexed are complete lists of cluster bodies and ceiling, pendant, special and weatherproof fixtures and miscellaneous materials. Many special and ingenious forms of fittings are described. The extensive lists give code word, catalogue number, description, list price and weight of package for each article mentioned. In its typographical and mechanical make-up the catalogue is unique and very convenient.

THE MASCHINENFABRIK OERLIKON, near Zurich, Switzerland, has distributed recently a number of publications of special interest. A well-illustrated bulletin of thirty-six pages describes the power plant and transmission system of the Societa Mineraria ed Elettrica del Valdarno in Italy. A seventy-two-page bulletin gives a full description of the single-phase railway from Seebach to Wittingen, Germany. Other publications are devoted to the 52,000-volt power transmission system from Gaucin to Seville, electric installations driven by wind power, high-speed motor generator sets and automatic limit devices for electrically driven cranes.

THE WHEELER CONDENSER AND ENGINEERING COMPANY, Carteret, N. J., has published a 24-page booklet entitled "Surface Condensers." The subject matter includes chapters on the economy of running condensing, the advantages of different types of condensers, and a description of Wheeler surface condensers. The Volz combined feed-water heater and condenser, in which some of the tubes serve as a primary heater, is described, and there is a section on turbine condenser outfits. The final part of the catalogue is devoted to notes and suggestions on the installation and operation of surface condensers. The illustrations show the various types of Wheeler Admiralty and Wheeler-Volz surface condensers and waterworks condensers, and a number of the large steam power plants of the country. This booklet is one of a series of engineering treatises which the Wheeler Condenser and Engineering Company is distributing, and will be of interest and value to any engineer who is called upon to design, construct or manage steam plants.

THE PETTINGELL-ANDREWS COMPANY, Boston, is marketing a number of devices designed to prevent the theft of current. In the forthcoming issue of the company's new publication, Juice, the "O. K." fuse block cover and "O. K." meter connection block are to be described. The former is a device for covering branch blocks so as to prevent illegal connections or the refusing of blocks on discontinued services. The meter connection block makes it possible to carry the service wires in conduit from entrance to meter, leaving no exposed wires in the customers' premises. This block is designed to facilitate the testing or replacement of meters, without interrupting the customers' service, or the necessity of opening tap joints or cutting wires. These two devices are being extensively used by some of the larger central stations, and the knowledge of their merits will undoubtedly be of interest to every central-station man.

RECORD OF ELECTRICAL PATENTS.

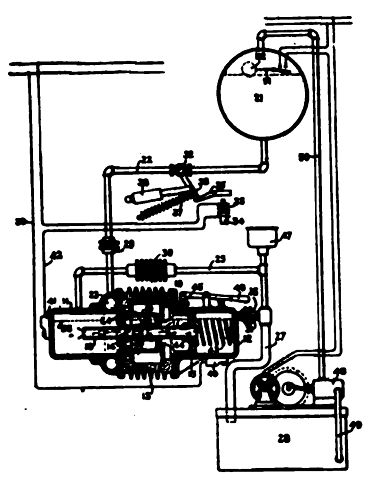
Issued (United States Patent Office) October 27, 1908.

901,939. CUT-OUT BOX. Thomas Q. Andrazyk, Chicago, Ill. Filed July 29, 1907. An asbestos-lined cut-out box.

901,942. WAVE-RESPONSIVE DEVICE. Clifford D. Babcock, New York, N. Y., assignor to United Wireless Telegraph Company, New York, N. Y. Filed August 27, 1906. The device has an adjustable contact engaging a spring contact arm.

901,944. CAR TRUCK. Asa F. Batchelder, Schenectady, N. Y., assignor to General Electric Company. Filed January 29, 1908. The motor armature is mounted on one axle and a combined bolster and motor field is supported on the side frame.

901,957. TELEGRAPHIC CODE CONDENSER. Matthew B. Dickie, Glasgow, Scotland, assignor to Nobel's Explosives Company, Limited, Glasgow, Scotland. Filed February 21, 1908. Three circular scales are arranged parallel and have different numbers and letters.



901,967.—OIL SWITCH

901,958. RAILWAY SIGNAL. Heinrich Diehl, Berlin, Germany, assignor to General Electric Company. Filed April 23, 1907. Means carried by the moving car throw light on selenium cells, which control the signal.

901,965. PREPARATION OF ELECTROTYPE MOLDS. Albert W. Harrison, Baltimore, Md. Filed July 16, 1906. The ingredients are in the proportion of one gallon of water, one ounce of kainite and a small quantity of graphite.

901,966. SOLUTION FOR TREATING ELECTROTYPE MOLDS. Albert W. Harrison, Baltimore, Md. Filed December 7, 1906. This solution consists of nitrate of soda dissolved in water, with graphite added thereto.

901,967. OIL SWITCH. Edward M. Hewlett, Schenectady, N.Y., assignor to General Electric Company. Filed November 7, 1904. A circulating oil system comprises a reservoir and a pump for storing oil under pressure therein.

901,974. TELEPHONE REPEATER. Lucius A. Lindsey, Crystal Springs, Ga. Filed March 20, 1906. The repeater has a carbon button, one plate of which is attached to the diaphragm.

901,975. RACK-RAIL LOCOMOTIVE. George E. Lynch, Columbus, Ohio, assignor to Jeffrey Manufacturing Company. Filed January 26, 1906. A motor-driven locomotive.

901,976. CURRENT-COLLECTING MEANS. Campbell Macmillan, Schenectady, N. Y., assignor to General Electric Company. Filed February 12, 1906. A rotating collecting ring and a stationary ring are connected by a rotating contact member.

901,977. MICROPHONE APPARATUS FOR TELEPHONE AND OTHER CIRCUITS. Quirino Majorana, Rome, Italy. Filed July 7, 1906. There is provided a liquid supply tube and an elastic connection between the diaphragm and the outlet end of the tube.

901,981. SUSPENSION DEVICE FOR TROLLEY WIRES OR OTHER CONDUCTORS CARRYING CURRENTS OF HIGH VOLTAGE. George A. Mead, Mansfield, Ohio. Filed December 2, 1904. A bracket has an insulator sleeved thereon. A trolley wire is supported by the insulator and an insulated brace rod is connected to the wire.

901,993. CARBON PENCIL OF ELECTRIC ARC LIGHTS. John Nicholson, Frackville, Pa. Filed April 20, 1908. This arc lamp electrode comprises a cored carbon pencil having a metal cap and metal jacket.

901,997. ELECTRIC RAILWAY SYSTEM. Horace F. Parshall, London Wall, London, England, assignor to General Electric Company. Filed August 19, 1904. A switch on the car for automatically changing the car circuits from single-phase trolley to direct-current third rail.

902,003. ELECTRIC FIREPLACE. Alfred D. Rathbone, Grand Rapids, Mich. Filed February 4, 1908. The heating element is made luminous.

902,004. PLURAL-LAMP FIXTURE. Frank J. Russell, New York, N. Y. Filed October 20, 1906. A wireless cluster bracket.

902,014. SIGNALING SYSTEM FOR RAILROAD TRAINS. Shellman T. Stewart, Newark, N. J. Filed January 31, 1908. This system is equipped with gates to make and break the signal circuit and latches for locking the gates and a second circuit to operate the latches.

902,017. ELECTRIC CAR TRUCK. Fernando F. Stowe, Worcester, Mass. Filed March 10, 1905. Renewed March 16, 1908. On the truck frame is an electric motor and spring-pressed cone bearings holding the motor in place in the frame.

902,019 and 902,020. DYNAMO-ELECTRIC MACHINE. Karl Sulzberger, Charlottenburg, Germany, assignor to General Electric Company. Filed April 8, 1905, and December 12, 1906. A rotating field magnet has a distributed winding and special winding holders arranged between the parts of the same.

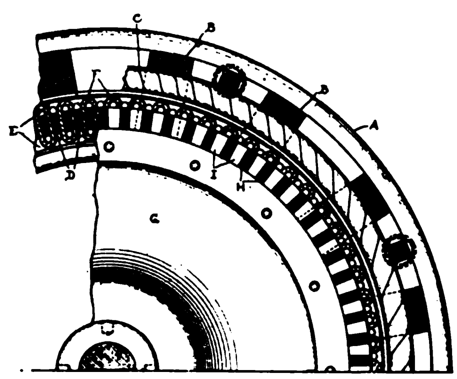
902,024. ELECTRIC HEATER. Elihu Thomson, Swampscott, Mass., assignor to General Electric Company. Filed June 17, 1907. In this heater is a fluid container, an electric heating device and a casing forming a condensing space for the fluid.

902,026. RAIL BOND. Eugene W. Vogel, Chicago, Ill., assignor to the Railroad Supply Company, Chicago, Ill. Filed February 9, 1906. The bond has shallow superficial grooves in its outer surface.

902,028. ELECTRIC SIGN. Henry J. Walser, Cleveland, Ohio. Filed May 29, 1906. This is an advertising display sign.

902,032. INCANDESCENT ELECTRIC LAMP. Willis R. Whitney, Schenectady, N. Y., assignor to General Electric Company. Filed October 31, 1904. The patent relates to the base terminals.

902,033. SWITCH MECHANISM. John B. Wiard, Lynn, Mass., assignor to General Electric Company. Filed April 28, 1906. A reversing switch has two sets of resilient contact fingers and a rocker member.



902,195.—TELEPHONE RELAY

902,035. ELECTRIC RAILROAD SWITCH. Merle J. Wightman, New York, N. Y. Filed January 2, 1908. A motor-operated track switch.

902,040. WIRE CONNECTOR. Homer W. Wyckoff, Indianapolis, Ind.; Nathan H. Richardson, administrator of said Homer W. Wyckoff, deceased. Filed March 12, 1906. Two metal plates are placed on each side of the wire and clamped together by a bolt.

902,043. TELEPHONE TRANSMITTER. George F. Atwood, East Orange, N. J., assignor to Western Electric Company, Chicago, Ill. Filed March 12, 1906. The containing case of the transmitter has a chamber secured to its rear wall.

902,048. MOLDED RESISTANCE. Lawrence E. Barringer, Schenectady, N. Y., assignor to General Electric Company. Filed February 2, 1906. Constituents are comminuted conducting material and hydrous silicate of calcium.

902,061. MOTOR CONTROLLER. Henry F. Elshoff, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Filed June 30, 1906. A multiple-voltage controller has a drum controlling the resistance switches.

902,065. DYNAMO-ELECTRIC MACHINE. Allan B. Field, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Filed May 13, 1907. A rotating field has damper rods extending through its field poles.

902,069. INCANDESCENT LAMP. Hugo Gernsback, New York, N. Y., assignor to the Motor Car Equipment Company, New York, N. Y. Filed March 12, 1907. A number of filaments are adapted to burn in parallel. Non-conductive stiffening members connect their feed wires.

902,074. SPEED INDICATOR. John L. Hall, Schenectady, N. Y., assignor to General Electric Company. Filed February 28, 1906. Electrically controlled means periodically lock a constantly rotating and an intermittently rotating member together.

902,099. SELECTIVE SIGNALING DEVICE. Ira F. Manny, Milwaukee, Wis., assignor to the Manny Signal Company, Milwaukee, Wis. Filed December 12, 1907. A motor-driven rotary member has escapement teeth engaged by the pawl and a signaling member that can be engaged by the pawl when it is moved out of the path of the teeth.

902,101. MOTOR CONTROLLER. Anthony L. McHugh, Cincinnati, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Filed June 30, 1906. A modification of No. 902,062.

902,105. ELECTRIC BELL. Charles H. North, Cleveland, Ohio, assignor to the North Electric Company, Cleveland, Ohio. Filed April 22, 1905. An adjustable weight is slidably mounted on the bell tapper for adapting the bell to selective actuation by different currents.

902,106. METHOD OF AND MEANS FOR UTILIZING THE PRESSURE IN THE INTERIOR OF AN ELECTRIC CONDUCTOR CARRYING CURRENT. Edwin F. Northrup, Philadelphia, Pa., assignor to the Leeds & Northrup Company, Philadelphia, Pa. Filed March 1, 1907. Chambers containing a liquid conductor communicate with each other by a passage from a point near the center of one chamber to a point more remote from the center of the adjacent chamber.

902,108. MOTOR CONTROLLER. William D. Pomeroy, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Filed December 31, 1906. A switch biased toward closed position is arranged to be opened by the drum when the latter is moved between certain positions.

902,118. SIGNAL SYSTEM. Burt A. Slater and Michael J. McDermott, Boise, Idaho. Filed March 5, 1908. An electric block signaling system for railways.

902,121. ELECTRIC FIXTURE. Edgar C. Suiter, Olympia, Wash. Filed April 30, 1907. A slack adjusting device for drop lamps.

902,157. PROCESS FOR PRODUCING PHOSPHORIC ACID. Frederick J. Maywald, Brooklyn, N. Y. Filed September 10, 1902. A low potential arc is applied to a granular mass of phosphates.

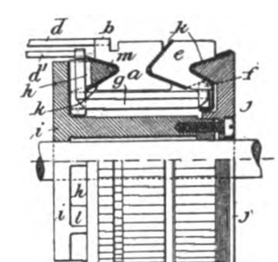
902,173. ELECTRIC CELL. Georges Schaull, London, England. Filed September 18, 1906. The metallic plate is a compound one, composed of a continuous fluid-tight plate and a perforated plate in metallic contact therewith.

902,176. RAILWAY SIGNALING SYSTEM. Carl J. Schwarze, Adrian, Mich. Filed July 18, 1906. Combined with a trolley wire are signaling conductors mounted on each side thereof.

902,184. ELECTRO-PNEUMATIC BRAKE. Walter V. Turner, Wilkinsburg, Pa., assignor to the Westinghouse Air Brake Company, Pittsburg, Pa. Filed March 20, 1905. An electric application valve for controlling the supply of air to the brake cylinder and a normally open electric release valve for controlling the exhaust port.

902,195. TELEPHONE RELAY. Ernst F. W. Alexanderson, Schenectady, N. Y., assignor to General Electric Company. Filed January 25, 1908. A high-frequency induction alternator has its stationary field winding connected in the primary circuit and the stationary armature connected in the secondary circuit.

902,216. ELECTRIC LAMP FOR HELMETS AND SIMILAR HEAD COVERINGS. Johann H. Dräger, Lübeck, Germany. Filed January 2, 1908. Mounted in the helmet is a battery connected with an electric lamp.



902,424.—DUPLEX COMMUTATOR

902,235. CABLE TIP. Louis Kellner, New York, N. Y., assignor to Metropolitan Switchboard Company. Filed November 11, 1907. The cable conductor fits into a conical hole, at the outer end of which is a screw plug.

902,244. ELECTRICALLY-CONTROLLED LOCK. Edward W. Marvel, Philadelphia, Pa., assignor to William H. Hollar, Philadelphia, Pa. Filed May 12, 1908. Electric motors operate the locking mechanism.

902,262. INSULATOR PROTECTOR. Robert R. Sparks, Greenfield, Mass. Filed May 20, 1908. About the insulator is a removable jacket forming a housing.

902,275. BANK OF LOCKING SWITCH KEYS. Elmer R. Corwin and Charles A. Bals, Chicago, Ill., assignors to Corwin Telephone Manufacturing Company, Chicago, Ill. Filed March 28, 1908. In a party line switch depression of any one of the push-buttons operates locking bars whereby any of the push-button keys which has been depressed is released.

902,285. CONDUIT. John A. Garey, Mound City, Mo. Filed August 12, 1907. A pair of loosely mounted plates is held by springs to form a wholly-closing shield for the third rail.

902,297. RAILWAY SIGNALING APPARATUS. Winthrop K. Howe, Buffalo, N. Y., assignor to General Railway Signal Company, Buffalo, N. Y. Filed November 27, 1905. Renewed June 6, 1908. A double signal is operated by a motor through an electromagnet clutch for each signaling part.

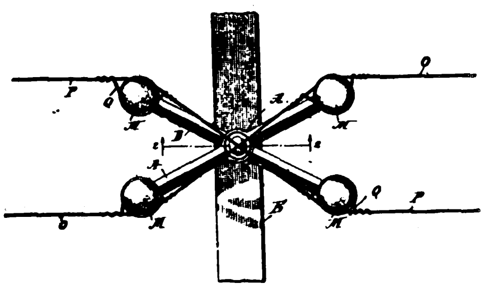
902,307. ELECTRIC CONTROLLING DEVICE. Harry W. Leonard, Bronxville, N. Y. Filed May 13, 1905. This motor starting box has an auxiliary movable contact device, carried by the main control switch, and means for causing this contact to quickly close the circuit independently of the rate of movement of the switch.

902,320. GAME REGISTER. Edward O. Parker and Harold E. Grey, Independence, Iowa. Filed April 19, 1906. Electrically operated means advance an index step by step and simultaneously operate an electromagnetic signal apparatus.

902,338. TELEPHONE SYSTEM. Paul V. Smith, Lyons, Kan. Filed December 22, 1906. An intercommunicating system.

902,354. ELECTRODE FOR ARC LAMPS. Willis R. Whitney, Boston, Mass., assignor to General Electric Company. Filed December 10, 1903. An electrode formed from a pure metal having a melting point higher than iron and yielding a luminous or flaming arc.

902,356. FOUR-PARTY-LINE INDICATING - RINGING KEY. Charles S. Winston, Chicago, Ill., assignor to Kellogg Switchboard and Supply Company, Chicago, Ill. Filed August 3, 1907. There are four switch-actuating plungers and four auxiliary plungers, one for each of the previous ones to indicate the last one that has been depressed.



902,455.—TRANSPOSITION BRACKET

902,373. SPARK-PLUG ATTACHMENT. Frederick D. Casey, North Water Gap, Pa. Filed July 25, 1907. A cover for the plug has an opening to permit the passage of a conductor.

902,389. APPARATUS FOR CONNECTING CONDUCTING AND OTHER WIRES. Anthony Fodor, Budapest, Austria-Hungary. Filed November 14, 1907. Holding and twisting devices are independently adjustable, and there are means for locking the holding device in position.

902,396. CONTROLLING SYSTEM FOR ELECTRIC MOTORS. Jay H. Hall, Cleveland, Ohio, assignor to Electric Controller and Supply Company, Cleveland, Ohio. Filed March 13, 1906. A master controller for a number of motors.

902,420. TROLLEY GUARD. William D. Lewis, Plymouth, Pa. Filed April 11, 1908. A guard frame is provided at one end with a segment-shaped enlargement.

902,424. COMMUTATOR FOR DYNAMO-ELECTRIC MACHINES. Frederick H. Loring, London, England. Filed December 31, 1907. Two independent commutators are arranged side by side, integral projections being formed on the end face of one commutator and entering recesses on the end face of the adjacent one.

902,427. ELECTRIC SPARKING DEVICE. Willie H. R. Mildeprath, Jacksonville, Fla. Filed January 20, 1906. A stationary electrode is associated with a movable electrode operated by an electromagnet.

902,455. TRANSPOSITION BRACKET FOR INSULATORS. James E. Skinner, Kingman, Kan. Filed June 17, 1908. A pair of superimposed hubs is provided with radially projecting arms, having bearings at the free ends.

902,476. ELECTRIC LOCOMOTIVE. William Dalton, Schenectady, N. Y., assignor to American Locomotive Company, New York, N. Y. Filed July 22, 1907. There are two swiveling trucks having each a pair of guide wheels at each end and two pairs of driving wheels between the guide wheels.

902,499. INDUCTOR MAGNETO-ALTERNATOR. Leon Le Pontois, New Rochelle, N. Y., assignor to Hurd & Haggin. Filed October 24, 1907. A diamond-shaped field frame has the windings at the nearer corners, which have soft iron internal poles adjacent to a rotor.

902,513. ENDOSCOPE. Reinhold H. Wappler, New York, N. Y., assignor to Wappler Electric Controller Company, New York, N. Y. Filed January 11, 1908. An electric light bulb is screwed into the socket member.

902,522. ELECTRIC-CIRCUIT CONTROLLER FOR INTERNAL-COMBUSTION ENGINES. Charles Cuno, Oconomowoc, Wis., assignor to Connecticut Auto Engineering Corporation, Meriden, Conn. Filed September 19, 1906. A contact arm carried by the shaft engages an insulated contact block carried by the case.

REISSUES.

12,871. PROCESS OF TREATING NEGATIVE-POLE PLATES. Joseph Bijur, New York, N. Y., assignor to the General Storage Battery Company. Filed January 14, 1908. Original No. 485,391, dated February 26, 1907. (Division A.) The process consists in soaking the plate in a solution of sugar, in depositing sugar in its pores and ultimately carbon, then drying the plate and heating it to carbonize the sugar and forming a final inert deposit of carbon.

12,872. NEGATIVE-POLE PLATE. Joseph Bijur, New York, N. Y., assignor to the General Storage Battery Company. Filed January 14, 1908. Original No. 845,391, dated February 26, 1907, (Division B.) A Planté plate characterized by having inert material incorporated in the active material and a substantially sustained capacity in use.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired November 3, 1908:

462,231. ELECTRIC RAILWAY. E. M. Bentley, New York, N. Y.

462,237. ELECTRIC LIGHTING SYSTEM. J. I. Conklin, Brooklyn, N. Y.

462,261. AUTOMATIC ELECTRIC WELDING MACHINE. H. Lemp and C. G. Anderson, Lynn, Mass.

462,262. LAMINATED DIE, HAMMER, ETC., FOR ELECTRIC METAL-WORKING APPARATUS. H. Lemp, Lynn, Mass.

462,263. METHOD OF, AND APPARATUS FOR, CONSTRUCTING ELECTRIC-LIGHT OR OTHER LINES. H. Lemp, Lynn, Mass.

462,311. SYSTEM OF ELECTRIC LIGHTING. F. M. Garland, New Haven, Conn.

462,321 and 462,322. ELECTROMAGNETIC SEPARATOR. R. R. Moffat, New York, N. Y.

462,345. ELECTRIC SIGNALING SYSTEM. F. B. Wood, New York, N. Y.

462,348. GEARING FOR ELECTROMAGNETIC MOTORS. C. E. Chinnock, Brooklyn, N. Y.

462,353. ELECTRIC SWITCH. M. Hoopes, West Chester, Pa.

462,369. CONTROLLING DEVICE FOR ELECTRIC MOTORS. F. O. Blackwell, New York, N. Y.

462,407. ELECTRIC SWITCH. R. M. Hunter, Philadelphia, Pa.

462,418. METHOD OF, AND APPARATUS FOR, ELECTRICAL CONVERSION AND DISTRIBUTION. N. Tesla, New York, N. Y.

462,449. SECONDARY BATTERY. J. H. Palmer, Boston, Mass.

462,504. ELECTRIC CURRENT METER. J. T. W. Olan, New York.

462,513. AUTOMATIC SIGNAL APPARATUS. J. B. Stewart, Haverstraw, N. Y.

462,532. ELECTRIC COOKING STOVE. J. V. Capek, New York, N. Y.

462,540. INCANDESCENT ELECTRIC LAMP. T. A. Edison, Llewellyn Park, N. J.

462,578. TROLLEY FOR ELECTRIC CARS. R. D. Nuttall, Allegheny, Pa.

462,595. ELECTRIC RAILWAY. J. B. Sheldon and D. J. Murnane, St. Louis, Mo.

462,624. ELECTRIC ARC LAMP. T. Conroy, Kansas City, Mo.

462,672. CONDUIT ELECTRIC RAILWAY. A. J. Robertson, New York, N. Y.

462,673. ELECTRIC ARC LAMP. E. C. Russell, Boston, Mass.

ELECTRICAL REVIEW
AND
WESTERN ELECTRICIAN

VOL. LIII. No. 20. CHICAGO, SATURDAY, NOVEMBER 14, 1908. ISSUED WEEKLY

BY THE
ELECTRICAL REVIEW PUBLISHING COMPANY.
CHARLES W. PRICE, President.
STEPHEN H. GODDARD, Vice-President. H. S. TUTHILL, Secretary.
PHILIP S. DODD, Manager. C. W. FORBRICH, Assistant Treasurer.

PUBLICATION OFFICE: 204 DEARBORN STREET, CHICAGO.

The present publication comprises: ELECTRICAL REVIEW, VOL. LIII, No. 20; WESTERN ELECTRICIAN, VOL. XLIII, No. 20.

EASTERN DEPARTMENT . . . . 13 Park Row, New York.
Philip S. Dodd and E. E. Wood.
EUROPEAN OFFICE . . . . 42 Old Broad Street, London, E. C.
Henry W. Hall.

SUBSCRIPTIONS

One Year, United States $3.00
One Year, Canada 4.00
One Year, Foreign Countries 6.00
Single Copy, 10 cents. Back numbers, beyond one month, each . .25

Changes of address reaching this office later than Monday cannot be made until the issue next following.

Application made for entry at the Post Office at Chicago as second-class matter under the Act of March 3, 1879.

CONTENTS.

THE BUSINESS REVIVAL.

Immediately following the election there appeared from every quarter indications that business had taken a new hold upon things, and that, in spite of the improvement which had taken place for the past two or three months, and which it was feared had discounted the results of the election, we are about to indulge in a season of conspicuous prosperity. Large orders which were contingent upon the result of the election were put in force, and it is estimated that with the starting up of industrial undertakings in every part of the country, that over a million men have been put to work on full time, where for the past six or eight months there has been either partial or complete shutdown. That this should be the case is remarkable, because the statistics at present available show that although there has been a great falling off in the rate of production and the development of wealth for the past year, the totals do not compare unfavorably with the totals for the last two years; and these totals were far greater than had ever been built up before, and were considered phenomenal. It is positively the case that there has not been a great falling off, but what has happened is that there was a sudden and maintained check to the acceleration. The country was never in a better condition to cope with the opportunity for rapid assimilation of orders and for the proper handling of huge demands than at the present time. During the trying period of the past twelve months the agriculturist has built up a large bank balance, conservative handling of money resources has established plentiful reserves, the railroads have been overhauling their systems, the manufacturers have been making improvements which were impossible of consideration during the strenuous period which culminated a year ago last month, the stocks in store-yards and on the shelves have been depleted, and the people have learned great lessons in economy and the wisdom of harboring their perishable resources. Concurrently with the slacking of work in a great many industries, there was a retrograde flood of emigration, which will make it difficult for a number of the milling and mining industries to man their workings. The places of those who fled upon the approach of hard times will be filled, however, by a better class of workmen, and with the improved conditions of labor, which are bound to come with a more intelligent class of help, and with the better understanding of the relation of the employer and the employé, there will be a wiser distribution of the earnings and a greater spreading out and utilization of the purchasing power of earnable money, with the elimination of labor disputes and their contributing unfortunate conditions.

RAILWAY ACCUMULATOR CARS.

The Prussian Railroad Administration has recently been experimenting with accumulator cars, running upon the system of suburban lines around Mayence. Passenger cars of the side-opening compartment type, carrying sixty persons, have been used for some time, and their operation has been so satisfactory that it has been decided to considerably increase the number of accumulator cars upon these lines. The accumulators are stowed under the seats of the car, in each of the six compartments with which the cars are fitted. The cells are placed permanently in position and arrangements are made for facilitating the examination of connections and for easy charging. The cars are able to cover a distance of thirty-six miles when running at a speed of twenty-four miles an hour on a single discharge of the 180-cell battery, which has a capacity of 230 ampere-hours at the 100-hour discharge rate. With this capacity the cars can make two trips to the suburbs and return without recharging.

The 180 cells represent a total weight of about ten tons, and their energy capacity is therefore about 3.1 watt-hours per pound. The life of the positive plate is estimated at 62,500 car-miles, and that of the negative plate at 37,200 car-miles. The cost of the entire equipment, including the battery, electrical installation and car, amounts to $6,750.

There are many installations where the accumulator car would be advantageous, particularly for cross-town traffic, where the run is short and the traffic does not justify the laying down of an elaborate conduit system, and where the city restrictions prohibit the use of the overhead trolley. For long distances, where the traffic is very heavy, the accumulator car does not appear to be a paying investment.

One of the unfortunate features of what appeared to be essentially a successful system operating in New York city only a few years ago was the distress caused by the fumes, which poisoned the atmosphere of the car while in transit. It is stated that in the present installation this is overcome by a system of ventilation which gives a good supply of air to the interior of the compartment in which the cells are placed, carrying away the fumes from contact with the air which is breathed within the car.

ELECTRIC FIRE PUMPS.

Recent tests of the motor-driven fire pumps which have been installed for the high-pressure fire service in New York city have focused attention on the valuable addition that such a system affords to the fire-fighting apparatus of a large city. The fire loss in all large cities, no matter how well equipped they may be with fire-fighting apparatus, has always been of great magnitude, and a considerable expenditure can be made for additional fire-fighting equipment with no possible opportunity for criticism because of unnecessary extravagance. In line with the satisfactory results of the tests in New York, the Chicago Board of Underwriters has appointed a committee of five to confer with the city authorities regarding a proposed ordinance requiring standard standpipes and fire pumps in all buildings of 100 feet in height, that can be used by the city fire department. For some time this has been urged as a solution of the hazardous condition presented by the congested district, and as a ready means of protection until the proposed high-pressure system can be installed. It is believed that each building can thus be equipped to take care of any fire within itself or within its immediate neighborhood, without being forced to depend upon engines outside. The installation of electrical pumps which can be started in operation by pressing a button is perfect. Figures have been secured from manufacturers showing that a 500-gallon pump could be installed for $1,750, and would require a fifty-horsepower motor; while a 1,500-gallon pump would cost $2,900, and would require a 150-horsepower motor. These pumps would be able to maintain a constant pressure at the pumps of 100 pounds above the city pressure, giving a pressure of approximately forty-five pounds on the top story of a fifteen-story building.

Where a building is kept under steam all night the probability is that steam-driven pumps would be practicable, but where there is a shutdown of steam, or where a building is isolated from its source of power, not even an internal-combustion engine can take the place of an automatically controlled electric motor for quick starting and dependability in the face of an emergency.

THE ELECTRICAL SMELTING OF IRON.

On another page of this issue there appears a letter from Mr. C. F. Elwell concerning the electrical smelting of iron. Mr. Elwell has been engaged in testing out a system of electrical smelting at Heroult, Cal., and his estimate of the cost of production is interesting.

In the issue of the ELECTRICAL REVIEW for August 15 we reviewed the efforts which have been made recently to bring about a commercially practicable electric furnace, and described the work of H. H. Noble in California. From the figures available at that time it was concluded that this furnace could be applied successfully only under special conditions, and that it could not compete with the large blast furnaces.

In the present communication Mr. Elwell states that an estimate of $16.14 as the cost of producing a ton of pig iron is well within reason. Pig iron is worth $28 per ton on the Pacific Coast, and the freight rate is $2 per ton to San Francisco. Under these conditions it would seem that a price of $25 per ton. f. o. b. Heroult was practicable.

As far as competing with the larger units is concerned, Mr. Elwell is of the opinion that a fifteen-ton furnace, using 1,500 kilowatts, can be operated commercially, and that larger furnaces using more power will soon be put into operation. These larger furnaces will involve mechanical feeding and other elaborate labor-saving devices, which will tend to keep the cost of production at a point at which the electric furnace can be entirely successful in localities adapted to its use.

LOW-VOLTAGE TRANSFORMERS FOR METALLIC-FILAMENT LAMPS.

Electrical supply may be materially extended by the frequent use of low-voltage transformers with metallic-filament lamps. Such an extension will benefit electric manufacturers, central stations and consumers alike.

A large part of residence lighting is now being done with gas and kerosene, and low-voltage transformers with metallic-filament lamps will go far to secure this lighting for electric stations. Sign and outline lighting are other branches of service that may be much extended by the same means.

Two factors, the relatively high first cost and the high candlepowers of metallic-filament lamps, stand between central stations and the full benefit that may be got from the increase of efficiency represented by the difference between three watts and one and one-quarter watts per candlepower.

At 100 watts or more the tungsten and osram filaments are inherently expensive, because of their considerable lengths, minute diameters, and the numerous points of support necessary. More than this, a lamp of thirty-two or even twenty candlepower is more than is wanted at many points about a house, or for parts of sign and outline lighting, and the cost of operating these lamps in such locations is often more than a consumer will pay.

At the price of $1.50 each, the cost of a forty-watt, thirty-two-candlepower tungsten lamp, burning 1,000 hours, is fifty-five one-hundredths of a cent per hour, with electric current at ten cents per kilowatt-hour. If an eight-candlepower, ten-watt tungsten lamp is sold for one dollar, its total cost is only twenty one-hundredths of a cent per hour of operation, other conditions being as before. No argument is required to show that this ten-watt tungsten lamp has a wide field of application that the forty-watt lamp cannot cover. To make the ten-watt tungsten lamp practicable, however, it must be operated at low voltage, say twenty-five or fifty, and it is for this reason that low-voltage transformers are coming into use.

In England and other parts of Europe, metallic-filament lamps of small candlepowers are regularly operated with special transformers at ten to fifty volts, and the manufacturers are now offering similar transformers in the United States. As a rule, these special transformers are located on the premises of consumers, beyond the meter and main switch, and take current from the supply circuit at the usual service pressures of 100 to 250 volts. The saving to consumers by the use of the high-efficiency tungsten lamps is so great that they can well afford to pay for these low-voltage transformers, and also for the small loss of energy in them. With the low-voltage transformer on the house side of the main switch, its core loss can of course be avoided, when lamps are not in use, by opening the switch.

The favorite voltages for house lighting with metallic-filament lamps, in England, appear to be twenty-five and fifty, and with tantalum lamps on short-circuits the necessary wiring is not heavy. There are other advantages, too, with the other high-efficiency incandescents, which affect the decision in their favor.

THE FUTURE OF METALLIC-FILAMENT LAMPS—A GERMAN VIEW.

In a recent issue of the *Elektrotechnische Zeitschrift,* Mr. H. Remané makes an interesting summary of the position of metallic-filament lamps. The popularity with which the sixty-candlepower or higher-power metallic-filament lamps have been received indicates to his mind that the people in general are in favor of units of greater illuminating intensity than the carbon-filament, sixteen-candlepower lamp. He believes that the osram lamp of about thirty-two candlepower will take the place of the sixteen-candlepower carbon lamp, especially when it is remembered that the cost of installing a certain total candlepower is reduced as the candlepower of the unit increases.

He does not agree with a number of our recent writers, who believe in the future of the 220-volt, metallic-filament lamp. Undoubtedly the higher-voltage lamp is less efficient than the 110-volt lamp, and experience has shown that if the 110-volt lamp works at one watt per candlepower, the 220-volt lamp will require for the same length of life a constancy of about one and one-quarter watts per candle in sizes of forty candlepower to 100 candlepower. Mr. Remané does not think that the lamp makers' skill will bring about any considerable percentage of increase in either the life or efficiency of the 220-volt lamp, because of the fineness of the filaments, which prevents their being safely handled in quantities, the inevitable variations in diameter, and other mechanical difficulties which enter into the construction of the higher-voltage lamps. The economies introduced in the wiring system by the higher voltage are hardly likely to reduce the cost of current sufficiently to effect a commercial competition with the 110-volt lamps, with their slightly more expensive system of wiring.

THE CHICAGO MUNICIPAL LIGHTING PLANT.

A report has just been made to Mayor Busse, of Chicago, by Mr. Bion J. Arnold, acting as engineer, and Mr. Arthur Young, acting as auditor, indicating that the city of Chicago would save from $200,000 to $300,000 a year by abandoning the manufacture of electricity and purchasing current entirely from private sources. The report shows that the taxpayers have sunk $3,639,031 in the plant and equipment, which now have a book value of $2,603,144, or an actual value of $2,353,869. It cost the city last year $81.64 to maintain each of the 7,647 street lamps. At the same time, the city is renting lights from the Commonwealth Edison Company at $75 per lamp per annum. In the report it is estimated that if the city steam plants were abandoned, the city could purchase current from private companies, under a special contract, at a cost of from $52.50 to $63 per lamp per year. The municipal department of electricity has been conducted by City Electrician Carroll with good judgment and great economy. In spite of this, the cost for municipal service has been continually increasing, and with a correct system of bookkeeping, wherein proper account is taken of depreciation, loss of taxes and upkeep, it is apparent that the cost to the municipality for generating its own current is greater than it would be under other circumstances.

The International Electrotechnical Commission.

Coincident with the International Conference on Electrical Units and Standards, but distinct from that body, there were held in London the sessions of the International Electrotechnical Commission. Both of these organizations are the outgrowth of the International Congress held at St. Louis in 1904. A preliminary meeting of the Electrotechnical Commission was held in London during June, 1906, at which the late Lord Kelvin was elected president and Col. R. E. Crompton, secretary. Provisional rules were also adopted subject to ratification by the several authorities that had appointed delegates.

On October 19 the first meeting of the Council was held in the Royal Colleges of Physicians and Surgeons, Victoria Embankment, London, with Sir John Gavey, chairman of the British committee, in the chair. A cordial address of welcome was made by the Right-Honorable A. J. Balfour. This was briefly responded to by Dr. E. Budde and M. Paul Boucherot. The first subject to come before the meeting was the election of a president to succeed Lord Kelvin. Dr. E. Budde nominated Prof. Elihu Thomson. Sir John Gavey seconded the nomination, and on a vote Professor Thomson was unanimously elected president of the International Electrotechnical Commission. He was immediately notified by telegram. Colonel Crompton was unanimously re-elected honorary secretary of the Commission. He then made a long report on the work done by the Commission, through its central office at 28 Victoria Street, Westminster, London. Ten countries had appointed committees, six were ready to do so, and six others were still considering the question. Colonel Crompton's report was adopted. Then there was a discussion of some of the rules proposed in 1906. The title "electrotechnical" and the location of the central office were adopted and the other suggestions postponed till the closing meeting of the Council. Owing to the small number of delegates present, the chairman proposed that all become members of the committee of the whole, which is designated by the title "Sous-Commission." This was done, and the subjects of nomenclature, standards of light, were referred to it.

With Prof. S. P. Thompson in the chair, the Sous-Commission met on Tuesday morning. A spirited debate ensued in regard to the rules submitted by the French delegates. In its final form the rule adopted regarding the method of reading conclusions was that each country be given one vote only, regardless of the number of its delegates, and that all recommendations require a four-fifths vote for passage. A system of international electrical nomenclature was then discussed. Doctor Budde, of the German committee, suggested cooperation with the technolexicon being prepared in Germany. This met with little favor, as it was regarded by the delegates that the scope of the Commission was rather to decide on certain electrical terms instead of compiling an electrical dictionary. The following recommendations on the subject of nomenclature were then adopted:

"Each electrotechnical committee should forthwith commence its work in nomenclature by preparing an electrotechnical glossary, arranged in alphabetical order, in its own language. These terms, together with their explanations translated into the official languages of the Commission (English and French), shall as soon as the list for the first five letters (A—E) is completed, be forwarded to the central office for communication to the other electrotechnical committees. The same procedure shall be followed for the next five letters, and so on, until the alphabet is completed. In carrying out this work each committee should, as far as practicable, utilize the work already done by others."

A discussion was then begun on a provisional standard of light. It was agreed to refer this subject back to the various committees for further consideration. The metric system was considered and practically adopted for the use of the Commission. A recommendation from the electrical congress at Marseilles that the Commission study uniform rules for interior wiring was postponed to a future meeting. Prof. S. P. Thompson then gave a very interesting address on the system of symbols proposed by Mr. Miles Walker. The chairman advocated the expression of Ohm's law in the same symbols by all nations. This matter was referred to the central office and the committees of the Commission for further study.

On October 22 the Sous-Commission resumed its meeting with the consideration of several minor matters of organization and then reported to a full meeting of the Council in the afternoon. The German delegates invited the Council to assemble in Berlin in 1910. After a vote of thanks to Sir John Gavey and Prof. S. P. Thompson for their courteous presidence and to Mr. C. O. Mailloux for his careful interpretations, the meeting adjourned.

An Interesting Lecture at Schenectady.

About 400 assembled Thursday night to hear the first of Dr. C. P. Steinmetz's three lectures before the Schenectady Section of the American Institute of Electrical Engineers, on "Thermodynamics."

Chairman E. J. Berg, in introducing Dr. Steinmetz, called attention to his work in improving the efficiency of electrical apparatus, which now in most instances is well above ninety per cent, and pointed out that in thermodynamics the engineers of the past have been confined to the use of empirical formulæ and efficiencies below ten per cent.

In the first of a series of three lectures on thermodynamics, Dr. Steinmetz proved that all phenomena incidental to heat can be explained by the assumption that heat energy is the energy of irregular motion.

He showed how the properties of solids, liquids and gases can be calculated from the same general equations which govern motion in general. The law of gravitation regulating the motion of fixed stars hundreds of thousands of times as large as the earth and separated hundreds of millions of miles in space also controls the relative motion of molecules, although the molecules are so small and so numerous that the smallest part of matter which can be weighed contains millions and millions of them.

In order to arrive at the equations governing heat, Dr. Steinmetz necessarily had to use a great deal of mathematics, part of which, no doubt, was not readily followed by a part of the audience. In concluding, he showed, however, that the practical application of these equations were simple and the equations tangible even for those not skilled in mathematics. The lecture closed by deducting the two fundamental equations of thermodynamics

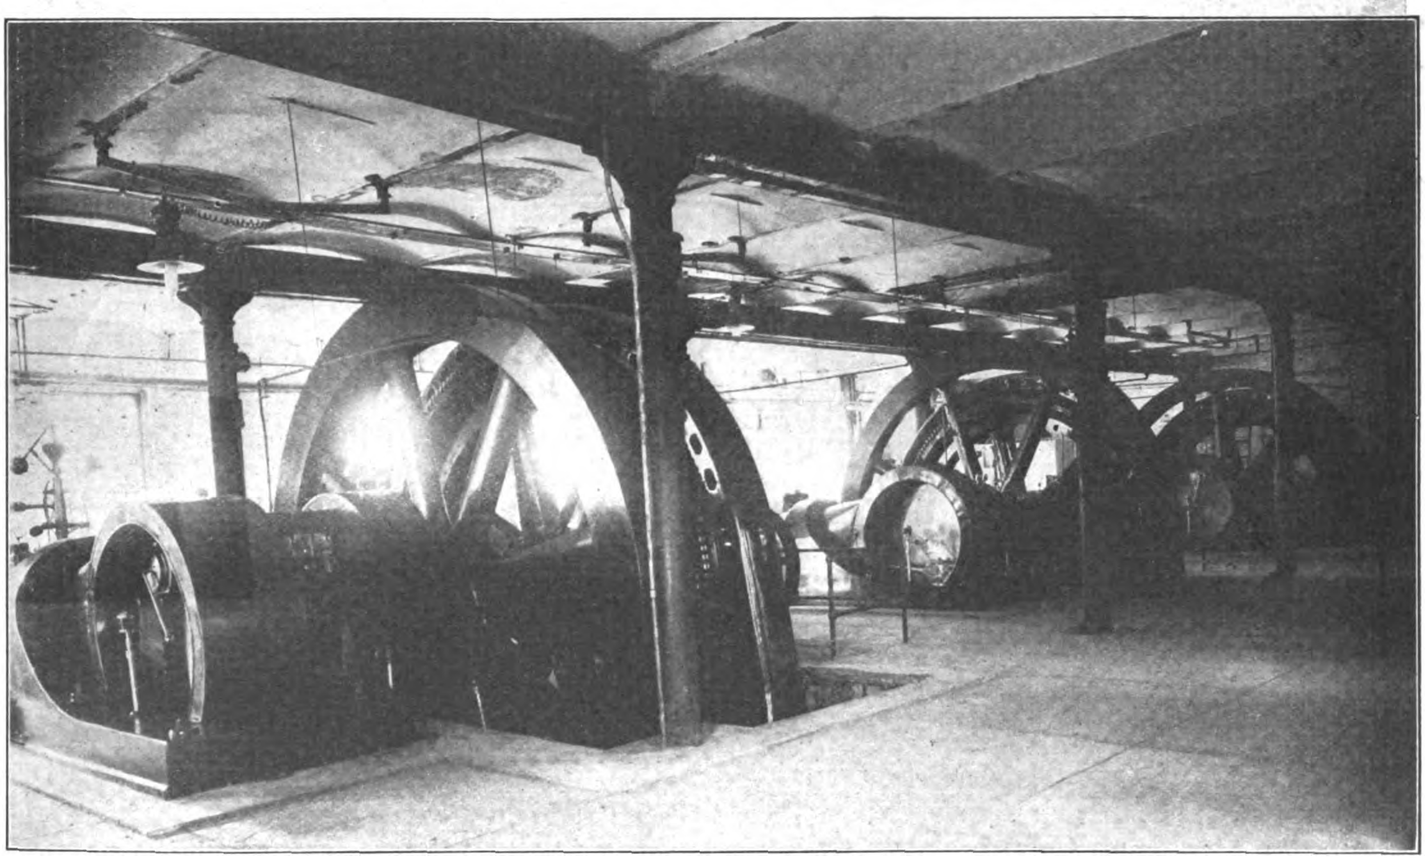
$$pv = \frac{RT}{W} \text{ and } pv^a = \text{constant.}$$

Mr. Berg, in closing, stated that the doctor's lecture was one of the most remarkable and interesting ever delivered before the local engineers. It provoked much discussion from W. L. R. Emmet and the other engineers, who insisted on Dr. Steinmetz clearing up some of the intricate problems involved, and which Dr. Steinmetz had presented in such a novel manner.

Electric Power Plant of the Missouri State Penitentiary.

A complete change in the method of power transmission has been brought about at the Missouri State Penitentiary, located at Jefferson City, Mo., by the installation of an electric power plant, and electric motors, which have replaced a number of steam engines.

The penitentiary has an average of more than 2,000 inmates, most of whom are employed in the various factories located within the prison walls. There are six shoe factories, one twine factory, one broom factory, one clothing factory, one saddle-tree factory, one harness shop, and one machine shop.



A VIEW IN THE POWER PLANT OF THE MISSOURI STATE PENITENTIARY.

Before the installation of the new electric power plant, each of these factories was driven by means of a steam engine, and these steam engines were supplied with steam from a boiler plant located outside of the prison walls. The steam engine in the twine factory, a 20-inch by 42-inch simple Corliss engine, was located at a distance of 1,500 feet from the boilers.

There were eleven steam engines used for driving the factories, in addition to the engines used for operating the dynamos for lighting and small-power service. The total indicated horsepower of all steam engines was approximately 900. The buildings were heated in some cases from engine exhaust, and in other cases with reduced high-pressure steam.

On account of the great amount of steam pipe installed, it was found to be practically impossible to keep it free from leaks and to maintain the proper steam pressure at the engines.

The fuel burned during the last year of operation of the old plant averaged about seventy tons per day; the coal used being mine run, equal to Illinois coal.

It was decided to install a complete new boiler plant adjacent to the old boiler plant, and a new centrally-located electric power plant, having sufficient capacity for operating all of the factories and for furnishing light and power for the State Capitol Building and other state buildings.

A new boiler house was designed to be constructed immediately adjacent to the old boiler house, and three Heine water-tube boilers, each of 500 horsepower capacity, were installed. Connection was made to the present brick stack by means of a long breeching, and a separate pump room was installed, this room containing the boiler-feed pumps and the feed-water heater. An independent steam connection was made connecting the new boiler plant with the engines installed in the new electric power plant. Arrangement was also made so that as soon as the new plant was placed in operation, the old boilers could be put in repair, and the steam connection from the old boiler plant was arranged for cross-connecting with the new steam main, and arrangements made so that reduced live steam from either of the boiler plants could be turned into the low-pressure heating mains.

The new electric power plant consists of three alternators, one of 500 kilowatts capacity, and two of 250 kilowatts capacity each; all of the alternators operating at a speed of 100 revolutions per minute, and direct-connected to simple Corliss engines, the large engine having a diameter of twenty-eight inches and stroke of forty-two inches; each of the smaller engines having a diameter of twenty inches and stroke of forty-two inches.

The dynamos and switchboard were constructed and installed by the Western Electric Company, and the steam engines by the St. Louis Iron and Machine Works.

Each dynamo was arranged with independent exciter, the exciter being driven by means of a Renold chain from the engine shaft. The dynamos are wound for 440 volts, three-phase, sixty cycles. All of the motors are wound for 440 volts, sixty cycles.

For the lighting service within the prison a transformer of 125 kilowatts capacity was installed, having a voltage ratio of 440 volts primary, 220-110 volts secondary.

For the purpose of lighting the Capitol Building and grounds, the Governor's Mansion, Supreme Court Building, etc., step-up transformers were installed having 2,300 volts secondary; this voltage being again reduced at the Capitol Building to the proper voltage for light and power.

The electric motors were furnished and installed complete by the Westinghouse Electric and Manufacturing Company. There are three 100-horsepower, two seventy-five-horsepower, one fifty-horsepower, nine thirty-horsepower, six twenty-horsepower, four fifteen-horsepower, three ten-horsepower, three five-horsepower and one two-horsepower machines.

These do not include the motors furnished and installed by the contractor for heating and ventilating purposes; there being thus used one seven-and-one-half-horsepower and one ten-horsepower motors.

The wiring for motors and power service between the power house and all of the buildings is installed under ground; McRoy conduit and paper-insulated, lead-armored cable, furnished by the Standard Underground Cable Company, being used. The underground work and electric wiring inside of buildings was installed by F. E. Newbery & Company, St. Louis, Mo.

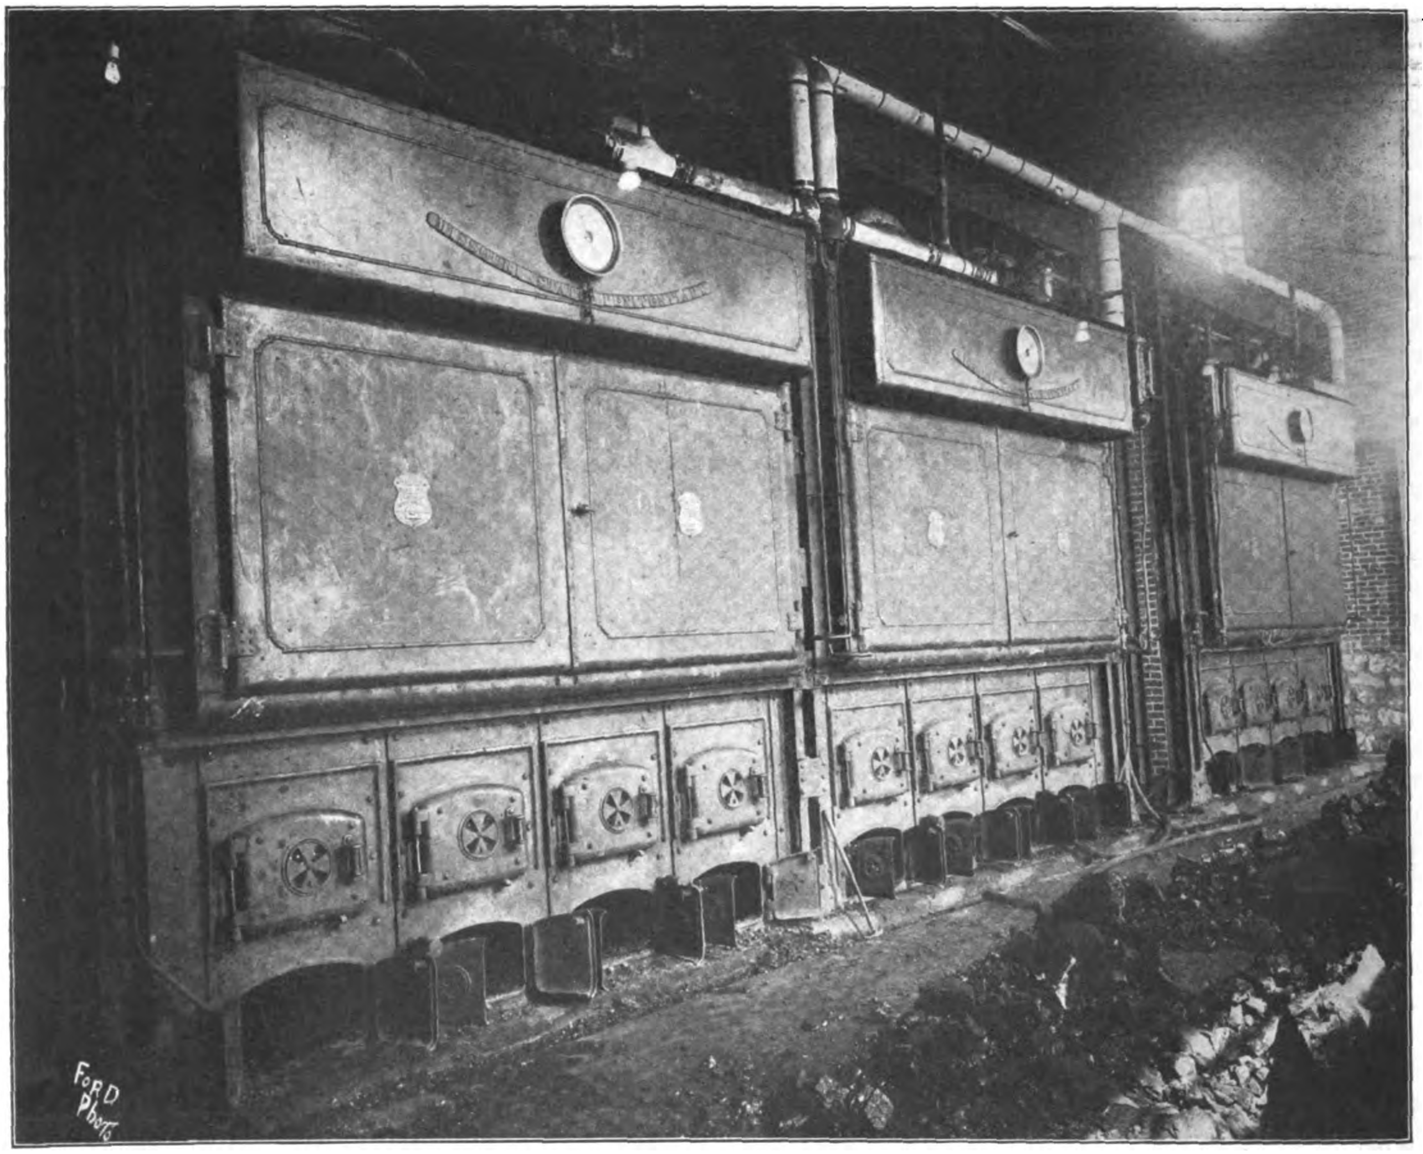
All electric lighting in the buildings is taken from one phase, and this phase is regulated by means of a Tirrill regulator. The arc lights around the prison grounds are divided on the phases, multiple Adams-Bagnall arc lamps being used.

All of the power piping and heating and ventilating systems were installed by the Peters-Eichler Heating Company, St. Louis, Mo.

The boilers are connected into a common header by means of a long bend, and one main steam pipe connects the new boiler plant with the engines in the power house. All of this work is run in tunnels.

The exhaust from the engines connects into a thirty-inch main, and arrangement is made for making direct connection with the boilers, through reducing valves, in case the exhaust from the steam engines is not sufficient for heating. The steam-heating supply starts with thirty-inch mains, and gradually reduces throughout the length of the run of the heating system.

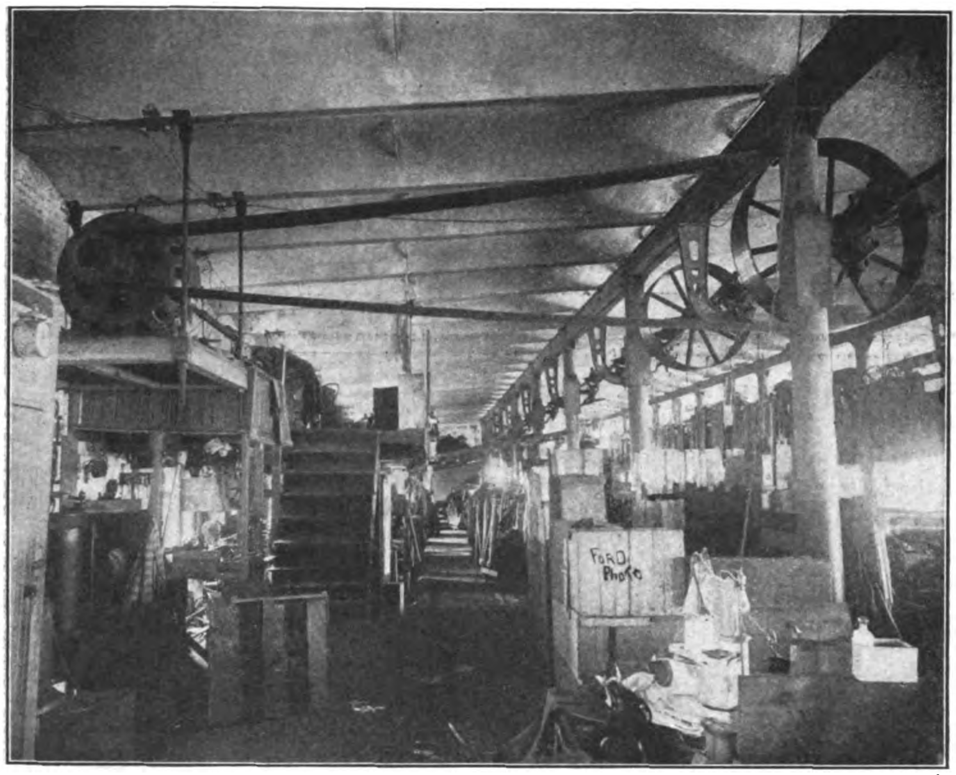
The buildings are all heated with pipe coils and radiators, with the exception of the Administration Building, Hospital Building and two cell buildings. All of these buildings are equipped with a hot-blast heating system, the two cell buildings being partially heated with pipe coils in addition to the hot blast. The hot-blast heating in all cases is automatically regu-



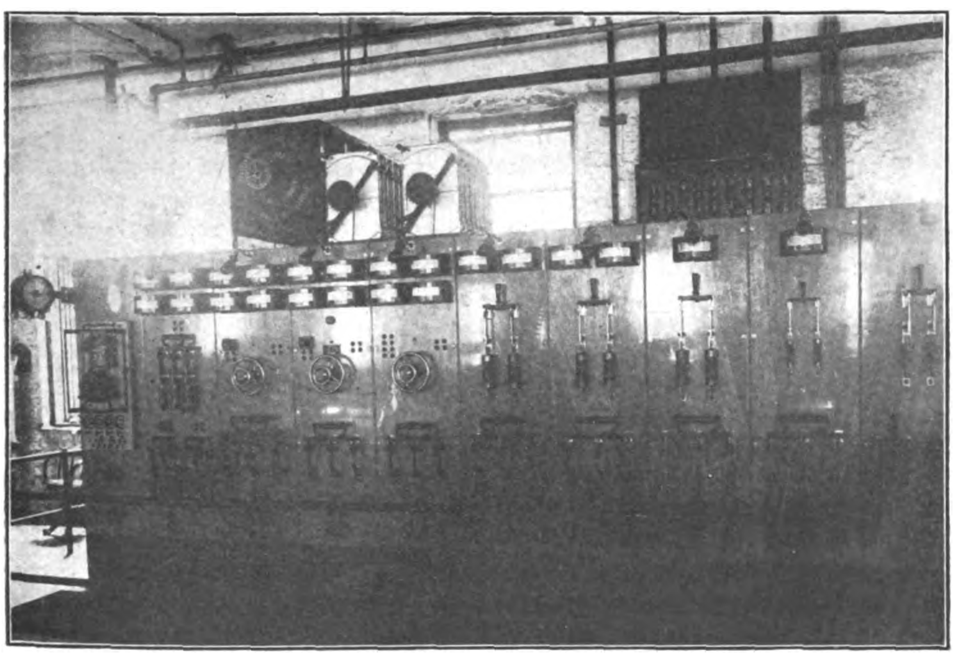
BOILER ROOM IN POWER PLANT OF MISSOURI STATE PENITENTIARY.

lated. The total amount of radiation in all buildings is approximately 85,000 square feet.

A duplicate set of pumps is installed at the lowest point of the prison grounds, and all returns are brought to this point, where they are taken by the pumps and returned to the new boiler plant.



AN EXAMPLE OF MOTOR DRIVE, MISSOURI STATE PENITENTIARY SHOPS.



SWITCHBOARD IN POWER PLANT, MISSOURI STATE PENITENTIARY.

An oil separator is installed in the heating mains near the electric power plant so that all steam used for heating is practically free from oil.

The new boiler plant and new electric-power plant were placed in operation about July 15. The entire change was made so that the work at the factories was not interrupted, and at the present time all factories are operated from the new power plant, and all of the old engines have been taken out of service and sold and moved from the premises. The old boilers are now being repaired and put in shape so that they can be used at any time should it be found necessary either for heating or power service.

It was found when the motors were placed in service that the indicated horsepower was considerably less than was the case when individual engines were used to drive the factories. The total indicated horsepower at this time is about 750 as against 900 with the old system. This is accounted for, in a measure, by the fact that a number of motors were used to replace one engine. In this way, all vertical belts were done away with, and in other ways the friction loss in the different factories was reduced.

The power plant was arranged so that the 500-kilowatt alternator could at any time carry the entire day power load, leaving either of the two 250-kilowatt alternators available for the night load, and in case of emergency the two 250-kilowatt alternators could be operated in multiple for carrying the power load, and the plant is now operating on this basis. It was found, however, in a test, that one of the 250-kilowatt alternators was able to carry the entire factory load for a day, so that this arrangement gives an abundant reserve capacity. This matter of reserve capacity is very important, for the reason that under the present contract arrangement for prison labor, a shut-down of the power plant would cost the state a considerable amount of money.

Since the new plant has been started, it has operated easily with two of the new boilers in service, and the fuel burned has been considerably reduced, the new plant having operated for one month on an average of about twenty-two tons of coal per day.

One object in the design of the power plant was to make it as simple and easily operated as possible, inasmuch as practically the entire power plant is operated by convict labor. Since the new plant was placed in operation, it was found that the service of about twenty-five of the convicts could be dispensed with as far as the operation of the power plant was concerned.

The installation of the new power plant was carried out under the management of Matthew W. Hall, Warden, and the Board of Prison Inspectors, consisting of Jacob Gmelich, treasurer of state; W. W. Wilder, Auditor of State, and H. S. Hadley, Attorney-General.

The plans and specifications for the entire installation, and the supervision of all work were under the charge of Ruebel & Wells, consulting engineers, Chemical Building, St. Louis, Mo.

QUESTIONS AND ANSWERS.

Ayrton Universal Shunt.—How is it that the multiplying power of an Ayrton universal shunt remains the same regardless of the resistance of the galvanometer used in connection with it?—M. A. G., Chicago.

In the accompanying diagram the arrangement and connections of a common form of this galvanometer shunt are shown. It was designed by the late Prof. W. E. Ayrton to be used with a galvanometer of any resistance. A plug placed in f sends all the current through the galvanometer G; plugs in f and j short-circuit the galvanometer; a plug in j alone cuts it out of circuit; in normal use a plug is left in h and another inserted in a, b, c or d, thus connecting in various portions of the coil r as a shunt and the remainder thereof in series with the galvanometer. Let the resistance of the latter be represented by g and that of the shunt by s. Let I be the total current, Is that portion thereof passing through the shunt, and Ig the portion passing through the galvanometer. Then

$$\frac{Is}{Ig} = \frac{s}{g + r - s}$$

and

$$\frac{Ig}{Ig + Is} = \frac{s}{g + r - s + s}$$

or

$$\frac{Ig}{I} = \frac{s}{g + r}$$

therefore

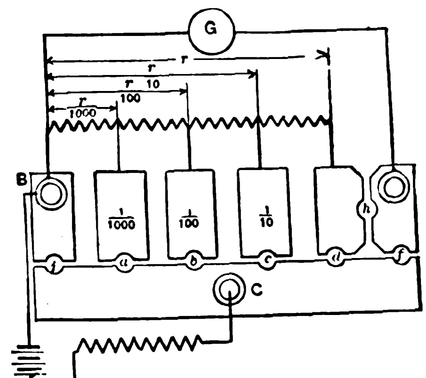
$$Ig = I \frac{s}{g + r}.$$

Since s is always equal to a decimal part of r, it may be written $s = \frac{r}{n}$, where n has the value 1, 10, 100, 1,000, etc.

Hence $Ig = \frac{I}{n} \frac{r}{g + r}$. The value $\frac{r}{g + r}$ is constant for any particular galvanometer used in connection with the shunt box and represents the ratio of the galvanometer current to the total current when $n = 1$, i. e., when there is a plug in h and another in d or f. When this other plug is in any hole but j, n has the values given above, regardless of the value of g. If r or g are not known the absolute value of I can not be determined from the galvanometer readings. The diagram given herewith is from Foster's "Electrical Engineer's Pocket-Book."

Relation of Watts to Volt-Amperes.—Please tell me why a kilowatt meter reads ahead of the kilovolt-amperes at certain times.—C. R., Mobile, Ala.

In general the reading of a wattmeter in kilowatts is less than the product of the voltage and current in kilovolt-amperes. The ratio between the former or true power to the latter or apparent power is the power-factor, which is always one or less than one. In a single-phase circuit the wattmeter will always indicate the same or less than the apparent power. In a polyphase circuit, when the power-factor is less than one and the two-wattmeter method is used, one wattmeter will read more than the true power in that phase and the other wattmeter will read less than the true power in its phase, in fact sometimes even negative. The algebraic sum of the readings gives the true total power. The reason for this difference in readings in a three-phase circuit is that one wattmeter reads the average product of the instantaneous resultant current and voltage in one phase multiplied by the cosine of thirty degrees plus the angle of lead or lag, while the other wattmeter reads



AYRTON'S UNIVERSAL SHUNT.

the average product of the instantaneous resultant current and voltage of another phase multiplied by the cosine of thirty degrees minus the angle of lead or lag. The effect of this difference of angles is to cause one wattmeter to generally read more than the volt-amperes of its phase.

Exide Accumulators.—What are the constituents of the Exide accumulator and its rating in voltage and amperes at full charge?—G. W. A., Morocco, Ind.

The Exide accumulator is of the common lead storage-battery type in which the positive plates are of lead peroxide, the negatives of a spongy form of lead and the electrolyte is dilute sulphuric acid. The name "Exide" is a trade name used by a well-known storage-battery company to designate its storage batteries for automobile use. Fully charged, this battery, like other storage batteries, gives an electromotive force of two to 2.1 volts per cell, which gradually diminishes during the discharge to about one and eight-tenths volts at its end. A fully charged cell has a discharge capacity in ampere-hours, dependent on its size. For example, a sparking-battery cell having five plates of type "S" is nominally rated at forty ampere-hours at the service discharge rate.

Behavior of Alternators in Parallel.—What would happen if two three-phase alternators were running in parallel and one should lose its excitation, as, say, by accidental opening of the exciter circuit or breaking of the exciter's belt? If two similar machines were running in parallel and the fuse in one phase of one machine should blow, would the other two phases still remain intact?—R. W. B., Kankakee, Ill.

In the first case the machine that lost its excitation would continue to run as an induction motor supplied with current by the intact machine operating as a generator. If the combined load for this generator should prove to be too large, its circuit-breakers will doubtless open, leaving the motorized machine now idle but probably still driven by its own prime mover. Blowing the fuse in one wire of a three-wire, three-phase machine cuts off the load from the two adjacent phases depending on this wire for their common lead. If the added load is too great for the other machine the fuse in its corresponding wire will blow, or it may be so great as to blow all three of its fuses. If the machines are four-wire, Y-wound, and the original fuse in any wire but the neutral wire blows, it will probably cut out that phase alone, the other phases running on intact. The extent to which the system as a whole is affected is dependent on the amount of load on it at the time.

Excitation of Synchronous Motors.—Is it correct to increase the field strength of a synchronous motor as the load increases? If so, why?—J. M. W., Portsmouth, Va.

Probably the chief reason for the use of synchronous motors as compared with induction motors is that they are capable of reacting on the line to give a leading current just as a condenser does. Therefore they are used to neutralize the effect of lagging currents due to induction motors, arc lamps or other inductive load, and thus to give unity power-factor in the system. For each particular load there is a particular value of field current that will give unity power-factor. Hence, to get the full benefit of the synchronous motor, it is desirable to increase the field current with each increase of load, the exact amount of increased excitation being determined best by adjusting the field current till a power-factor indicator indicates the ideal unit value.

POWER SUPPLY AND ITS EFFECT ON THE INDUSTRIES OF THE NORTHEAST COAST.[1]

BY CHARLES H. MERZ.

SCOPE OF PAPER.

In this paper, power supply refers to the provision of electricity for industrial use by companies[2] specially constituted for the purpose. It is assumed that the general effects of power supply on the industrial development of the district are likely to be of more interest to members of this Institute than would be a technical description of power-station plant, so that, beyond indicating by a schedule the extent and nature of the system, the paper deals chiefly with the general aspect of the question. Power supply, though of comparatively recent development, has already had a marked effect upon the industries of the northeast coast:

1. A great saving of coal and reduction of smoke has resulted; there is now, apart from the power company, practically speaking, no coal burned on the Tyne for power purposes except in chemical factories. The Tyne shipyards and engineering works may be said to have adopted electricity to the exclusion of all other forms of motive power.

2. The application of electricity to all new uses has been facilitated; the suburban traffic facilities of Newcastle are more ample than those of any other town of similar size at home or abroad; four new rolling mills are about to be driven electrically.

3. New industries have been established in the district purely because of the cheap power supply available.

4. A substantial commencement has been made in the utilization of the waste heat and gases existing in the area, and in this regard the district occupies a unique position, owing to the extent to which its future power requirements can be met by electricity produced as a byproduct of two of its largest industries, the making of pig iron and the making of coke.

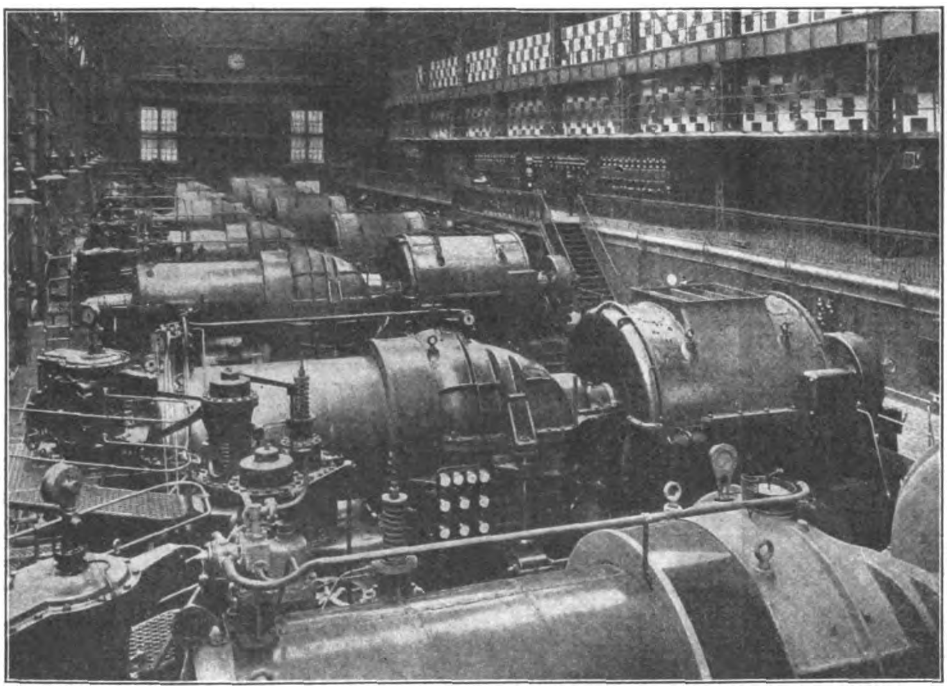


FIG. 1.—CARVILLE POWER STATION.

NATURE OF NORTHEAST COAST INDUSTRIES.

The problem of power supply in any district is so completely governed by local conditions that it may be permitted at the outset to summarize the nature and extent of the staple industries of the northeast coast. The table below does this in convenient form:

	Population. 1901.	Coal Mined. 1906. Tons.	Make of Coke. 1906. Tons.	Ironstone Mined. 1906. Tons.	Pig Iron. 1906. Tons.	Shipping Built. 1906. Net Tonnage.
N.-E. Coast industrial area...	2,015,000	52,097,377	7,830,000	6,126,324	3,628,651	630,872
United Kingdom	41,458,721	251,067,628	19,296,526	15,500,406	10,109,453	1,156,771
Ratio:— N.-E. Coast / United Kingdom	4.8%	20.7%	40.5%	39.5%	36.0%	54.5%

It will be seen that in coal, iron and shipbuilding the northeast coast figures represent, respectively, one-fifth, one-third and one-half of the nation's output.

POLICY OF ELECTRIC-POWER COMPANIES.

It was early realized that the more completely the electrical wants of the whole community could be met, the more cheaply could a supply of electricity be given and the more stable would the supply industry become. Efforts were, therefore, made to design a system which would be capable of producing current at a minimum of cost and of providing a satisfactory supply for all purposes—power, traction and lighting.

EXTENT OF POWER SUPPLY SYSTEM.

The extent of the area to be covered necessitated the generation of electricity at a pressure and in a form facilitating transmission over long distances, while the nature of the market to be catered for made it essential that the current should be produced as cheaply as possible, which in turn involved the use of an extensive site with ample coal and water facilities. The station from which the greater portion of the current is now supplied—Carville—was begun in 1903 by the installation of 14,000 electrical horsepower of steam-turbine-driven generators producing three-phase, forty-cycle current at a pressure of 6,000 volts. This installation has been increased fourfold during the past four years, so that the generating plant now aggregates 56,000 electric horsepower, and Carville has now a greater output of electricity than any other public supply station in Europe. (See Figs. 2 and 3.) From Carville the transmission and distribution networks extend westward to and through the city of Newcastle-upon-Tyne, northward to Blyth, and eastward along the river Tyne to North Shields, while in a southerly direction the cables at present reach a point some thirty miles south of Carville, and extensions will shortly be completed linking up the northern cable network to the power system, which has now been in operation some eighteen months in the Middleboro district.

Unity of policy and uniformity of system on the part of the three power companies have been secured by working

[1] A paper read before the Iron and Steel Institute, at Middlesboro, England, September 28-29.

[2] The companies and municipalities supplying current in different sections of the northeast coast are twelve in number, but as nine-tenths of the total electricity sold is produced by the Newcastle-upon-Tyne Electric Supply Company, the Durham Electrical Power Distribution Company and the Cleveland & Durham Electric Power Company, and as the author's information is only complete so far as these companies are concerned, the remarks in this paper have application exclusively to these companies.

agreements. The development has gradually extended northward and southward from the Tyne, and it is now possible to obtain electricity on the same system throughout practically the whole area. The table herewith gives the number and size of generating stations and a few leading particulars of the transmission and distribution systems. The capacity of plant installed represents about one-ninth of the total plant installed in public supply stations of the United Kingdom. But as the power companies are working on a more constant load, i. e., a better "load factor," the electricity actually generated is about one-quarter of that generated in the whole of the public supply stations of the United Kingdom.

That of the Durham Collieries Company, the operation of which the Newcastle-upon-Tyne Electric Supply Company took over this year, was a fifty-cycle, three-phase system, while the Tees area of the Cleveland & Durham Electric Power Company, where supply was begun in January of last year, was originally designed for twenty-five cycles. The same company's Bishop-Auckland and Consett stations were designed, one to give three-phase, twenty-five-cycle current, the other two-phase, fifty-cycle current.

It will be appreciated that these alterations (involving in some cases the complete redesign of system) have necessarily delayed development, but it was felt better to sacrifice something for the sake of uniformity.[1] The work of making the systems uniform has now been completed, and, in addition, nine small, and therefore uneconomical, generating stations, not mentioned in the table, have been shut down.

PARTICULARS OF GENERATING STATIONS.

Power Station.	Type.	Horsepower of Plant Installed.	Type of Current.	Voltage.	Remarks.
Carville	Coal-fired.	56,000	3-phase 40 cycles	6,000	In operation.
Philadelphia	Coal-fired.	13,000	3-phase 40 cycles	6,000	In operation.
Neptune Bank	Coal-fired.	6,800	3-phase 40 cycles	6,000	In operation. (stand-by)
Grangetown	Coal-fired.	8,000	3-phase 40 cycles	12,000	In operation.
Hebburn	Coal-fired.	4,500	3-phase 40 cycles	6,000	In operation (stand-by)
Weardale	Waste-heat.	6,650	3-phase 40 cylces	3,000	In operation.
Newport	Waste-heat.	4,000	3-phase 40 cycles	3,000	In operation.

MAIN TRANSMISSION AND DISTRIBUTION NETWORKS.

Main Trunk System	3-phase 40 cycles	20,000 volts	Underground and overhead.
Main High-Tension Power Distribution System—			
Tyne and North Durham Area	3-phase 40 cycles	6,000 volts	Underground and overhead.
Tees Area	3-phase 40 cycles	12,000 volts	Underground and overhead.
Power Supply	3-phase 40 cycles	3,000 and 440 volts	Underground and overhead.
Railway Supply	Continuous current	600 volts	Third rail.
Lighting Supply (and Small Motors)	Continuous current	480 and 240 volts	Three-wire.
	and 3-phase 40 cycles	440 and 250 volts	Four-wire.

Though the extension of the power-supply system has been rapid, its development and the growth of its profit-earning capacity were considerably delayed by the work which had to be done from time to time to secure uniformity of system. Unfortunately, with each amalgamation or extension of area considerable alterations had to be effected in the system of the new company concerned. For example, the system of the Newcastle-upon-Tyne Electric Supply Company, the pioneer company, is a three-phase, forty-cycle system.

GENERAL AND LOCAL CONDITIONS GOVERNING POWER SUPPLY.

A factor invariably of vital importance in the production of cheap current, whether by a public company or by a private manufacturer, is the capital expenditure per useful horsepower of plant. This decreases as the size of plant grows, while the running efficiency at the same time increases. The local conditions governing power supply in this district are:

1. The low price of coal, enabling manufacturers to produce power themselves at relatively low rates.

2. The fact that the manufacturers' works are mostly of considerable size, i. e., their individual electrical requirements are large.

3. The existence of large quantities of potential energy in the form of waste heat and combustible gas.

The first and second conditions have been met by the power companies, in erecting their main generating stations (a) taking full advantage of the best coal and water facilities available, (b) installing plant of capacity much in excess of that which any individual manufacturer, however large, could adopt, (c) by catering for all classes of consumers, thereby securing a diversity of load with a resulting constancy of output, and so utilizing the plant installed to the best possible advantage. These factors, combined with the employment of a highly skilled technical staff and attention to numberless relatively minor details, have resulted in securing an efficiency of production much greater than that practicable to any manufacturer producing power merely as an auxiliary to his main business. This is, after all, an age of specialization, and the production of electricity from coal at a minimum of cost presents opportunities for the highest technical skill and for unremitting vigilance.

Power supply in this district began on the north bank of the Tyne. It has naturally, therefore, reached its highest development there, and although even in this section of the area it is only seven years old, there is at the present moment not a single firm of shipbuilders or engineers on the north bank of the Tyne inside the power company's area of supply which does not take ninety-five per cent of its power from the company, the remaining five per cent being produced from small gas engines or from boilers fired with scrap wood. On the south bank of the Tyne, progress has, since power supply started, been equally rapid, while in the Tees area, although the power company only began operations in January of last year, they have already connected over 20,000 horsepower of motors.

[1] From the point of view of uniformity, the important things are the type of current and the periodicity—the voltage itself can be easily transformed.

The credit of electrifying the Newcastle suburban railways is, of course, due to the enterprise of the North-Eastern Railway Company; but the fact that they were the first important English railway to electrify a portion of its system, and that it purchased the necessary electricity from the power company, shows that the availability of cheap power is an advantage not only to manufacturers but to the public generally in facilitating the introduction of electric traction. Since the electrification of the Newcastle system the train service has been more than doubled, and the schedule speed improved by twenty per cent. A comparison with other cities at home and abroad shows that no other town of similar population, or indeed having twice the population, has so extensive an electrified-railway system and so frequent a suburban service, and this has, of course, resulted in a large increase of travel.

The application of electricity to rolling mills of the largest size is one of the most interesting industrial developments of recent years. It had its origin in Germany, and is making rapid progress there. The advantages offered are economy of running, closer speed regulation, better control of operations, and fewer breakages. There are now four new electrically driven rolling mills being installed in this area—two by Dorman, Long & Co., one by the Bowesfield Steel Company, and one by a new company now being formed. The electricity for these will be purchased from the power company, so that in this direction also power supply has facilitated new developments.

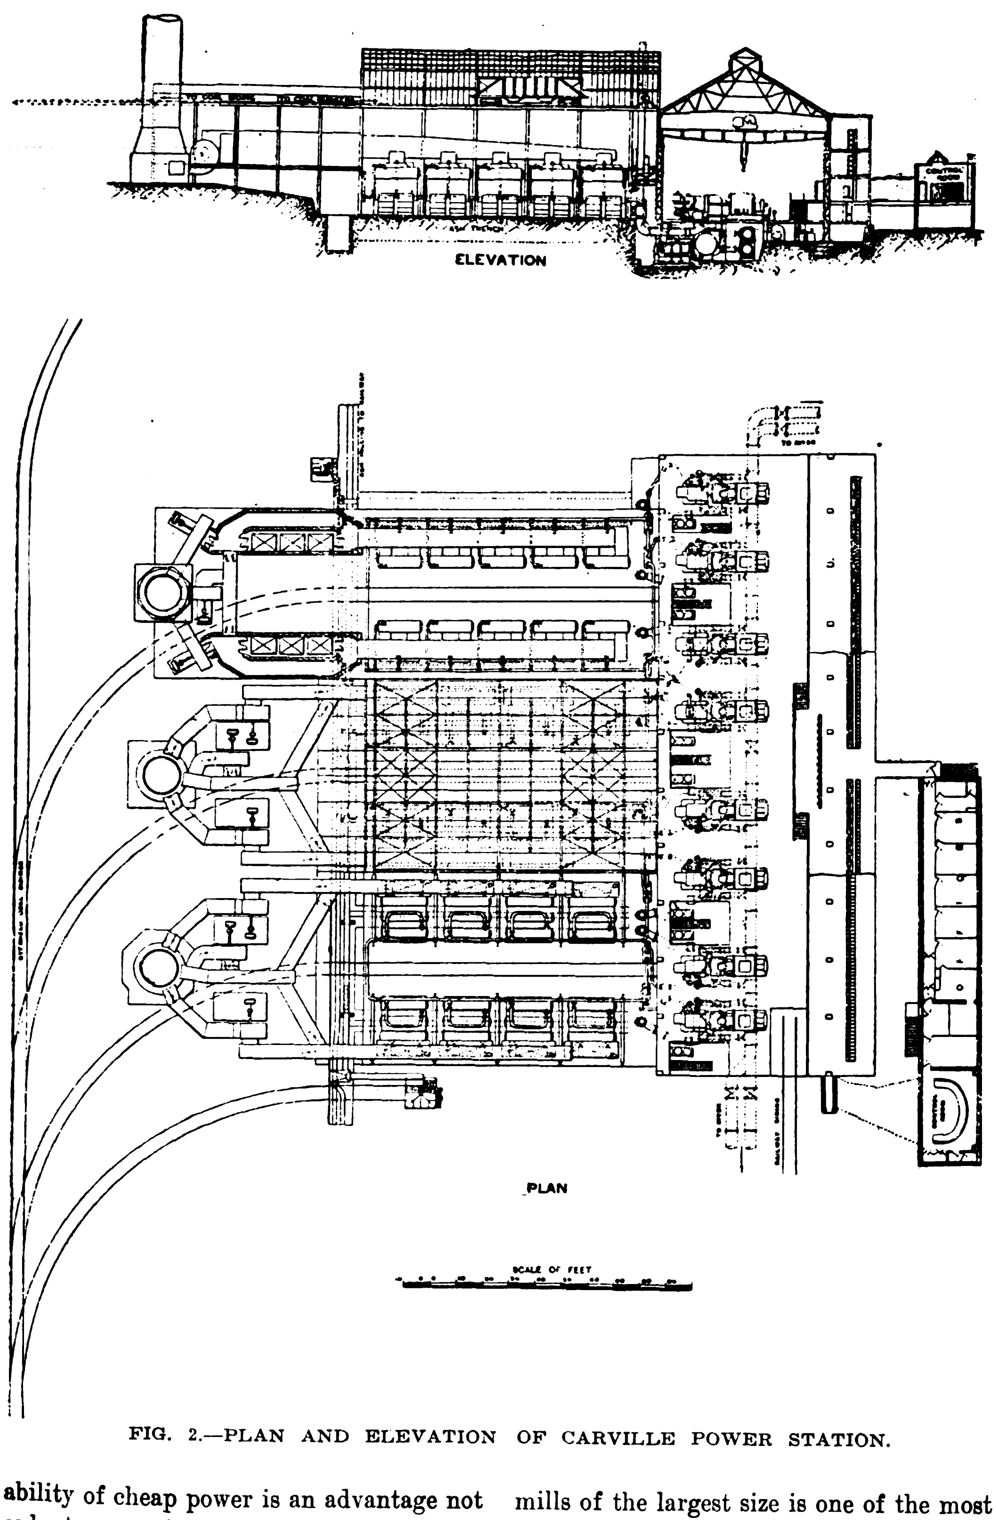

FIG. 2.—PLAN AND ELEVATION OF CARVILLE POWER STATION.

The supply of electricity to coal-mines, beginning as it did not more than four years ago, has not reached the same stage of development as in the case of other industries, though collieries having an output of some 8,000,000 tons per annum are taking, or are arranging to take, practically their whole supply from the power companies. This supply will include, among other apparatus, winders of 1,600 horsepower each; and it would appear that the supply of electricity to coal mines is likely to be of even greater magnitude than the supply to shipbuilding and heavy engineering works. In the latter case the effect has been to conserve over fifty per cent of the coal previously burnt for power generation.

The output of coal from Northumberland and Durham in 1906 was over 52,000,000 tons, and, according to the report of the Royal Commission on Coal Supplies, between six per cent and eight per cent of the total coal brought to bank is used by the collieries for the purpose of power generation. From the making of coke given by the table, it appears that about one-fifth of the coal mined on the northeast coast is converted into coke. Making a liberal allowance, therefore, for the power at present used from the surplus heat resulting from the coking process, the collieries of Northumberland and Durham must burn for their own power requirements some 2,500,000 tons of coal per annum. As the almost invariable rule is to work non-condensing, as the steam piping is usually long, and as a large portion of the load is intermittent, it is certain, and is proved by experience in this district, that the same power can be provided electrically in a large central power station by the consumption of less than a quarter of this coal. Apart, therefore, from the efficient utilization of waste heat discussed hereafter, apart from the saving of coal in shipbuilding and engineering works, and apart from the saving resulting from the electrification of railways, the application of electricity to coal mines in this district, when as complete as that to the Tyne shipyards, will render available for outside sale over 1¾ million tons of coal, equivalent to, say, over half a million sterling per annum.

SUMMARY OF PRESENT RESULTS.

To summarize present results, the three power companies are now responsible for the supply of current to eighty miles (single truck) of electrified railway, four tramway systems, the lighting in towns having populations aggregating over 700,000, motive power to the extent of 85,000 horsepower, and electrochemical works of over 12,000 horsepower. The last named are new industries attracted to the Tyne solely by cheap power supply, and there is every indication that their number will in future be largely increased.

SURPLUS OR "WASTE" ENERGY FROM COKE OVENS AND BLAST FURNACES.

This brings us to what is perhaps the most interesting section of the problem, and one which it is not too much to say is also of considerable national importance, namely, the efficient utilization of waste heat. The counties of Northumberland and Durham and the North Riding of Yorkshire last year produced together 7,800,000 tons of coke. The bulk of this was made in the older-fashioned beehive oven, but the retort type of oven, by virtue of the increased coke yield and of the recovery of the by-products, is making rapid progress, and it can be proved that were the whole of the above coke output produced in retort ovens, there would be available waste gas and waste heat capable of developing over 150,000 horsepower continuously, if used under boilers, or probably rather less than twice this amount, or, say, a quarter of a million horsepower, if the gas were used in gas engines.

The blast furnaces form a second but less important potential source of power. In evidence given before the Royal Commission on Coal Supplies, it was estimated that if gas engines were used exclusively for power purposes, then, after the requirements of the stoves and blowing engines had been met, there would still be available from the Cleveland furnaces a supply of surplus gas equivalent to 61,000 horsepower continuously.

THE UTILIZATION OF WASTE ENERGY AND ITS COMMERCIAL VALUE.

The question then arises as to the best method of turning this "waste heat" and gas to useful purpose. The problem is one of great moment, and however dealt with, will involve years of work before a complete solution can be achieved. It is, therefore, the more important that the efforts directed toward such a solution should proceed on a commercially sound basis and along correct engineering lines. On a rigorous analysis of the situation it will be found that financial and other practical considerations definitely limit the pace at which progress can be made, and, especially in the case of blast furnaces, greatly reduce the amount of power immediately available.

Many engineers, fascinated by the magnitude of the figures, have proceeded to calculate the commercial value of the gas; the more cautious of them by estimating the total heat units contained in the gas, and then calculating the value of the coal necessary to give the same heat units; others by first assuming the gas is utilized in gas engines, and then calculating the tonnage and value of the coal required to produce the same horsepower from steam engines. The second method gives a result twice as great as the first, which is itself already much too high, having left out of account the fact that the gas or heat in question can only be regarded as of the same value as coal if it can be utilized as cheaply from a capital expenditure point of view, if it can be stored as conveniently, and if it be available where and when required; in short, the commercial value of these waste products bears no direct relation to their value arrived at by either of the above methods.

Dealing first with the waste energy from coke ovens, each separate group of ovens usually consists of between forty and 120 ovens, rarely exceeding the latter figure. The batteries of ovens are widely scattered throughout the county of Durham, and are for the most part at relatively long distances from the populous centers—that is to say, from the centers of power demand. The gas might be piped to some central point, as is the practice followed in America with natural gas, which is transmitted in some cases 200 miles; but this natural gas has twice the calorific value of coke-oven gas, and it is usually available at a pressure of fifty pounds per square inch or upward, rendering it practicable to transmit a large volume of energy through a relatively small pipe, whereas, to transmit coke-oven gas any distance, there would have to be installed an expensive compressing plant. Further, there is, in addition to the gas given off from the coke ovens, a certain quantity of waste heat which can only be utilized locally under boilers; and in no calculations which the author has made has he been able to establish a case for the transmission of gas for power purposes as against the alternative of converting the gas into electricity and transmitting the power in this form. Admitting the desirability of converting the gas into electricity, the doubtful point then remaining is whether it is cheaper for an owner of coke ovens to put down his own generating station and to utilize the electricity so produced for his mines; or, alternatively, to cooperate with a power company, which he can do either by selling them the whole of the gas and

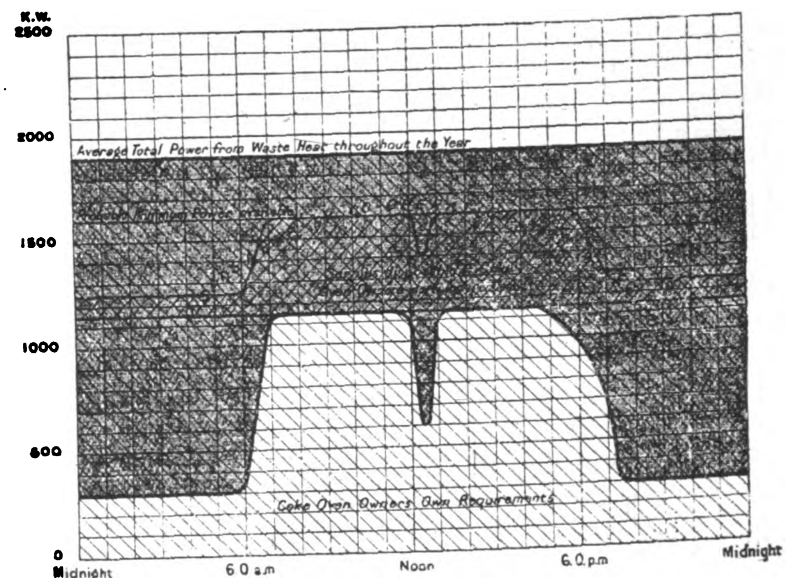

FIG. 3.—ESTIMATED DAILY OUTPUT AND LOAD CURVE OF WASTE-HEAT STATION AT CROOK.

Electricity utilized by coke-oven owners at mines and ovens=5½ million Board of Trade units per annum. Maximum surplus available for outside sale, if coke-oven owners work independently=2¼ million Board of Trade units per annum. Surplus disposable by cooperating with power company=ten million Board of Trade units per annum.

purchasing in return what electricity he needs; or, by undertaking to provide a portion of the capital required for generating stations, which, when erected, would be operated by the power company, and the profits shared between the parties.

COOPERATION WITH A POWER COMPANY THE MOST EFFICIENT MEANS OF UTILIZATION.

In all cases investigated by the author it has been found that a greater profit will accrue to the coke-oven owner by cooperating with a power company than by proceeding on independent lines. There are three reasons for this:

(1) When a private owner erects a generating plant independently, he must install some reserve or spare plant, with a consequent heavier outlay of capital than is necessary to a power company, which, possessing a coal-fired station, need install no spare plant in any of its waste-heat stations, but can, instead, meet any variation of load by the coal-fired station, which also acts as a standby against any breakdown.

(2) This necessity of putting down spare plant results in smaller, and therefore more expensive and less efficient, plant. To take a case: Supposing 2,000 horsepower is available, if the station is to be used in conjunction with the power company's system, one 2,000-horsepower unit would be entirely satisfactory, the power system acting as a standby. If it is to be used in a separate generating station, one would probably install three 1,000-horsepower units—two working and one spare. The gain in the former case in capital cost, running cost, and efficiency is obvious. As a matter of fact, the capital cost in the second case would be nearly double what it would be in the first.

(3) The power company, having a market for current many times greater than the output of any individual waste-heat station, can run such a station continuously at maximum output, so utilizing completely all the current that can be produced; whereas, it is impossible to conceive the power requirements of an individual coke-oven and colliery owner coinciding, even approximately, over twenty-four hours with the amount of gas or waste heat available.

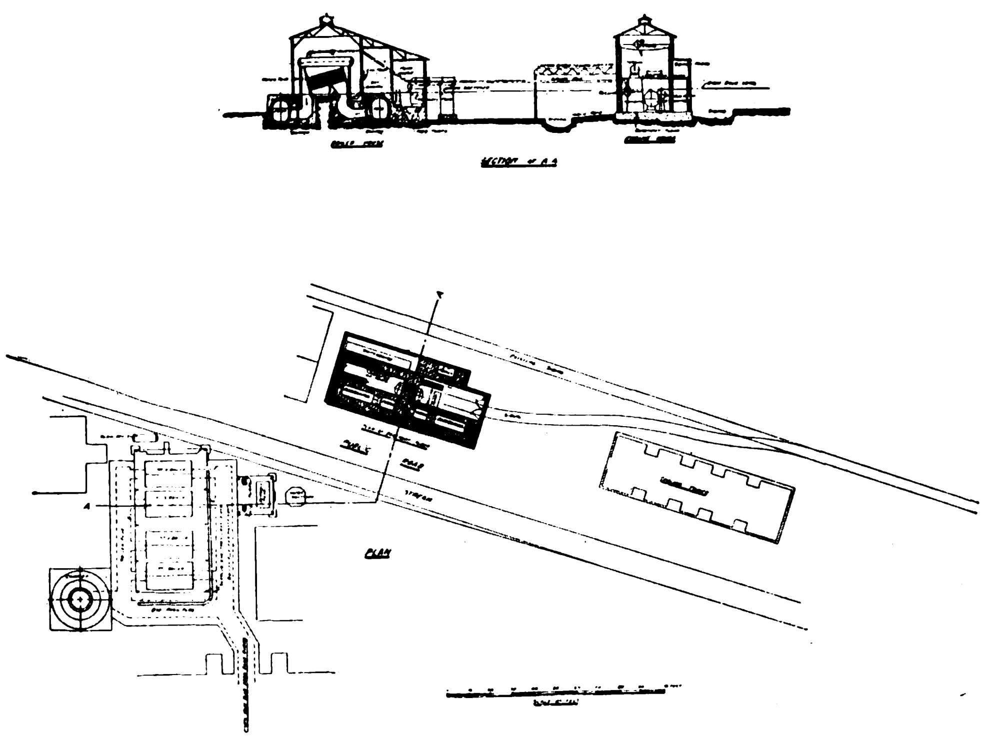

FIG. 4.—BANKFOOT WASTE-HEAT STATION.

The diagram (Fig. 3) which refers to Messrs. Pease & Partners' installation at Crook, shows the advantage of cooperation very strikingly. It will be seen that the area of the rectangle enclosed between the top line and the base (shown hatched) represents the total amount of power available, that "hatched" (but not shaded) the requirements of the colliery owner, and that "cross-hatched" the amount disposable had the colliery owner put in his own plant independently, and been able to find a purchaser; it also assumes that the outside purchaser had approximately the same load curve as the colliery owner himself, which is a reasonable assumption, unless the power be transmitted long distances, as the only users of power in the vicinity of coke ovens are other colliery owners. The area shaded gray represents the surplus power actually used under the cooperative arrangement.

THE COOPERATIVE PRINCIPLE AND BLAST-FURNACE GAS.

It is more difficult to get out so typical a curve in the case of blast furnaces, as the conditions vary so widely. Of course, if a company produces pig iron only, and does not convert the iron into steel, cooperation with a power company is at

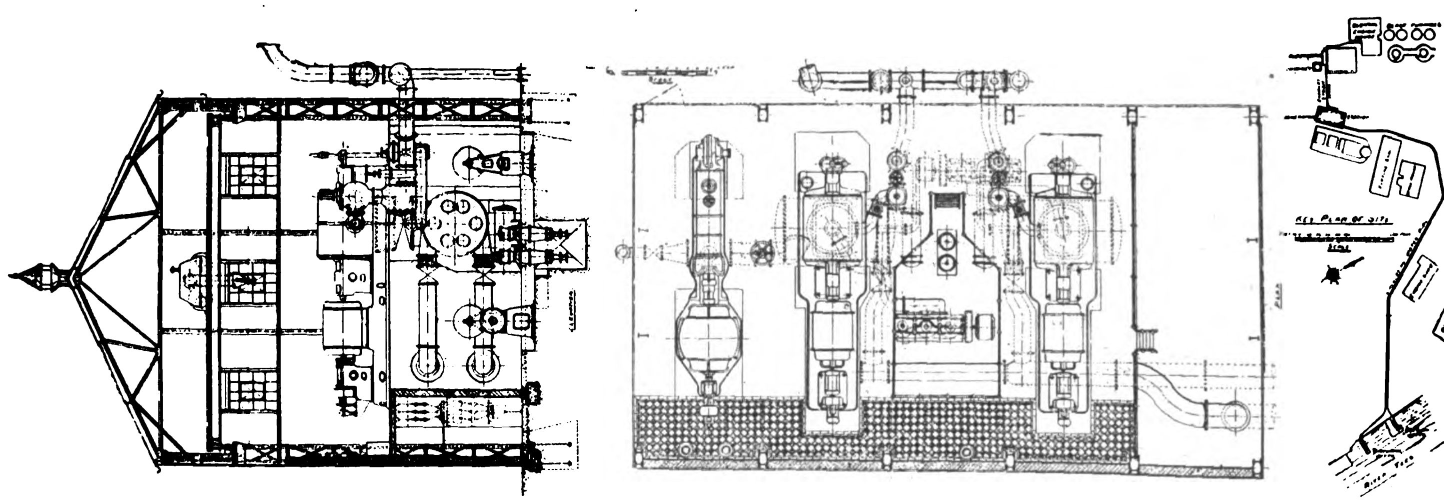

FIG. 5.—NEWPORT EXHAUST-STEAM STATION.

present, practically speaking, the only outlet which it has for its surplus power. If, however, a blast-furnace works has a steel mill attached, it may be argued that the correct thing to do is to follow the plan adopted by many large works in Germany, namely, to install gas-engine blowers and gas-driven dynamos at the blast furnaces, the latter plant producing the necessary power for driving the steel mills.

Capital charges are invariably the controlling factor in the total cost of electricity, and the question raised above, namely, whether it is commercially sound for a blast-furnace owner to cooperate with a power company or not, can only be decided in each individual case after full consideration of the capital outlay involved, the amount of spare plant that has to be provided, and the degree of coincidenec between supply and demand. It is clear that if it be decided to make the works self-contained, then the supply capacity must always be in excess of the possible demand; otherwise a risk is run of a portion of the works having to be stopped, and as the demand varies from time to time, there must be a variable amount of gas utilized, involving wastage when supply exceeds demand, or the burning of coal at certain periods when demand exceeds supply. Given an equitable arrangement, it is clear that the same general arguments in favor of cooperation which hold in the case of coke ovens are applicable to blast furnaces with steel works attached.

UTILIZATION OF BLAST-FURNACE GAS IN GERMANY.

As illustrating one aspect of the case, I quote from an article on the German Steelworks Union, published in the Financial and Commercial Supplement to the *Times*, dated July 3, 1908:

"The latter concerns (the German iron and steel works) have grown up under the economic impulse to find and employ the cheapest method of production in order to secure iron at the lowest possible cost. They have erected blast furnaces around their mills. . . . The gases formerly escaping from their furnaces and going to waste now supply a cheap motive power for their steel and rolling mills. They make their own coke, and the coking process furnishes valuable by-products, besides supplying, in many cases, an additional source of fuel gas for the power plants."

Later on, in speaking of the big iron producers who form the Dusseldorf Syndicate, the writer says that in spite of dull trade "the great works continue to smelt iron at almost the pace they set when the recent wave of prosperity was at its height. The economies involved in the situation almost compel them to do so. To a considerable extent, they have long-term contracts for foreign ores for mixing with home ores; their coking ovens must continue in operation for the sake of the by-products, and the coke produced would deteriorate in quality if stored. But more than this, the furnace gases are needed for driving their steel mills, and it is often difficult to blow out a furnace or two without seriously disturbing the power supply."

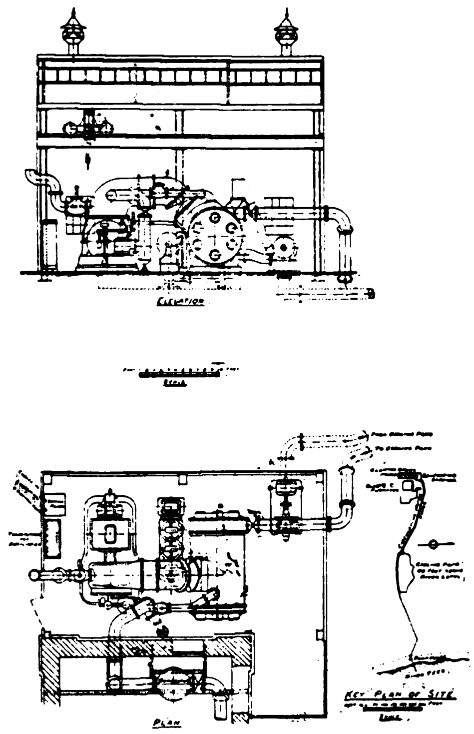

FIG. 6.—TEES-BRIDGE EXHAUST-STEAM STATION.

It would therefore appear that even after a rough approximate balance has been secured between supply and demand it is readily upset by ordinary market fluctuations. The natural variation of trade thus furnishes a further argument in favor of the cooperative principle.

COOPERATION WITH A POWER COMPANY THE ONLY MEANS OF OBTAINING FULL VALUE FROM SURPLUS ENERGY.

The power companies in this district having their transmission cables interlacing the entire industrial area, and being in a position, with their large load already developed, to utilize any amount of electricity whenever and wherever produced, are arranging for waste-heat stations at different points, turning all the electricity so produced into a common network from which the colliery company, the coke-oven owner, or the blast-furnace owner can purchase any amount he may require, all spare plant and all plant to deal with exceptional peak loads being kept at the main central coal-fired station. Such a policy applied to other commodities is as old as the hills; it began in the most primitive market when a producer gave his raw material and received in exchange manufactured articles, but so far as the author is aware this is the first time it has been extensively applied to electricity, although the principle so applied is equally sound, and it appears that only in this way is it possible to conserve the full national value of the energy now being wasted.

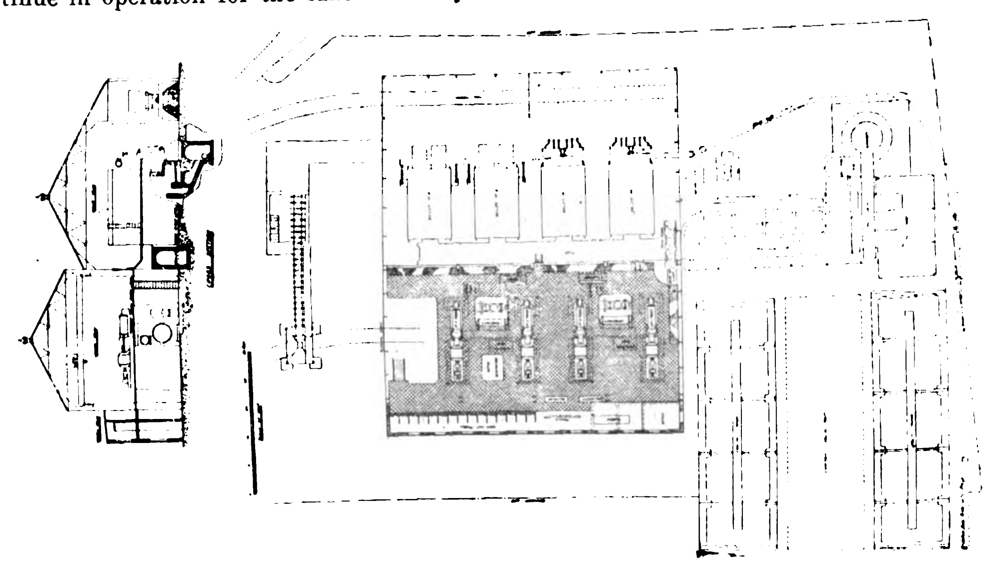

FIG. 7.—WEARDALE WASTE-HEAT STATION.

BRIEF OUTLINE OF WORK ALREADY DONE.

To summarize briefly, the work which has already been done in the utilization of surplus power, the first cooperative arrangement made by any of the power companies was brought about by the initiative of the owners of the Priestman Collieries, and resulted in the erection of the power station at Blaydon in 1905. At the present moment the three power companies have at work or in hand five waste-heat stations, three in connection with coke ovens, and two in connection with blast furnaces. Additional stations are under consideration.

To free any substantial quantity of gas for outside power users would involve therefore the substitution of gas engines for the existing steam blowers. Considerations of capital expenditure usually forbid this course, and had it not been for the genius of Mr. Parsons, whose exhaust steam-turbine provides another effective though less ambitious way of dealing with the situation the Cleveland furnaces could not be regarded by a power company as an immediately available source of energy.

In this connection, as capital outlay controls so completely the cost of electricity, and as exhaust steam turbines are so dependent on a high degree of vacuum for efficiency (at twenty-six inches they consume fifty per cent more steam than at twenty-nine), it is perhaps not always easy to justify the policy of installing small exhaust-steam turbines inland in conjunction with an intermittent supply of steam, such as that from a colliery winding engine, as this involves a cooling tower and a regenerator, with a consequent poor vacuum and high capital outlay.

The drawings (Figs. 4, 3, 6, 7) of typical waste-heat stations will, perhaps, be of interest. The Newport station, at Messrs. Samuelson's, and the Tees-bridge station are exhaust-steam stations, the Weardale station at Spennymoor is driven by coke-oven gas, while the Bankfoot station at Crook will derive its energy chiefly from waste heat from coke ovens. The Blaydon station also utilizes waste heat and gas from coke ovens.

The author is aware that it has lately become the fashion to argue that the resources of Great Britain have been developed on less scientific lines than those either of Germany or of America. He thinks, however, that the persons urging these views are in the majority of cases omitting to give full weight to local conditions. The fact that the connections to the local power companies' systems have recently been increasing at the rate of 20,000 horsepower per annum appears to him to prove fairly conclusively that manufacturers on the northeast coast are quick to avail themselves of new developments or of additional facilities.

Association of Car Lighting Engineers.

The Association of Car Lighting Engineers will hold its first annual convention in Chicago during the week of November 16. The opening session will be held on Monday morning at ten o'clock in the German Room of the Grand Pacific Hotel. The programme for this meeting includes addresses of welcome by city officials, followed with an informal talk by President A. J. Farrelly, and the secretary-treasurer's report, by G. B. Colegrove. Papers are to be read as follows: "History of Car Lighting," by P. Kennedy. "History of Axle Lighting," by W. L. Bliss. A paper on "Railway Train Lighting," which was read in Chicago on June 7, 1892, by A. H. Bauer, will be read by W. F. Bauer. The afternoon meeting will be given over to discussion of the topics of illumination and distribution of lights in cars, and the care and maintenance of storage batteries.

Tuesday morning will be taken up with the subjects of straight electric lighting of cars, and the head-end system, and in the afternoon lamps and axle-lighting will be discussed.

For the sessions of Wednesday the programme includes: "Straight Storage Lighting," "Organization and Systematizing of Work," and "Train Connectors and Wiring of Cars."

The convention banquet will be held Wednesday evening.

On Thursday morning at the closed meeting for active members the election of officers, selection of the next meeting place and other business will be transacted. In the evening an informal smoker will be held at the Grand Pacific Hotel. On Friday the car-lighting engineers will visit Milwaukee on a pleasure trip.

Meeting of the Chicago Electric Club.

The regular meeting of the Chicago Electric Club was held in the rooms of the Chicago Automobile Club on Wednesday, November 11, preceded by an informal luncheon at 12:15 o'clock. The guest and speaker was William Carroll, city electrician, who delivered an able address on the development of the Chicago lighting system, and made some interesting comparisons of the lighting system and those of other large cities. After the address several of the members present discussed the subject and asked a number of questions, which Mr. Carroll was pleased to answer.

Hudson River Water Power Bondholders' Committee.

A committee composed of F. J. Lisman, P. M. Chandler, of Chandler Brothers & Company, Philadelphia, and Arthur P. Stone, vice-president of the Commonwealth Trust Company of Boston, has been formed to represent the holders of the first mortgage five per cent bonds of the Hudson River Water Power Company, receivers for which were recently appointed. It is intended to increase the committee by representatives of the bondholders in Pittsburg and Canada. Bonds may be deposited with the Trust Company of America, New York, Commonwealth Trust Company of Boston, and the Real Estate Trust Company of Philadelphia.

Ohio Society of Engineers.

The annual meeting of the Ohio Society of Mechanical, Electrical and Steam Engineers will be held at Toledo, Ohio, November 20 and 21. Headquarters will be at the Secor Hotel. Among other papers to be read at this meeting will be "The Columbus Municipal Lighting Plant," by C. H. Gamper, Columbus; "The Laboratories of Electrical Engineering at Ohio State University," by Prof. F. C. Caldwell, Columbus; "Underground Heat Insulation of Steam and Hot-water Piping," by H. Gillett, Cleveland. David Gaehr has been appointed secretary to fill the unexpired term of W. B. Rowe, resigned.

FINANCIAL REPORTS OF ELECTRICAL COMPANIES.

MONTREAL STREET-RAILWAY YEAR.

The Montreal Street Railway Company's full pamphlet report for the year ended September 30, 1908, has been issued. This shows a surplus, after interest and rentals, available for dividends amounting to $1,136,411, or 11.36 per cent, on the $10,000,000 capital stock. The general balance sheet of the company as of September 30, 1908, shows a surplus of $2,042,296, with total assets of $17,394,647.

Included in the report of the Montreal Street Railway Company is the report of the Montreal Park & Island Railway Company, owned by the former. The income account is as follows: Gross, $277,634; expenses, $181,488; net, $96,145; renewals, $25,000; net income, $71,145; charges, $129,224; deficit, $58,078, which compares with $69,849 for 1907.

ALTERNATING CURRENTS AND THEIR APPLICATIONS.

BY EDSON R. WOLCOTT.

CHAPTER I. (PART VII.)—POWER IN ALTERNATING-CURRENT CIRCUITS.

CALCULATION OF POWER.

In a direct-current circuit the power can be calculated when the potential drop and the current are known, thus:

$$W = IE,$$

where E and I are, respectively, the effective values of the potential drop in volts and the current in amperes, W being the power in watts. On account of certain properties of the circuit the actual power delivered by an alternating-current generator is generally less than the apparent power or product of the electromotive force of the generator and the current flowing. Thus the power delivered by an alternating-current generator cannot always be determined by a voltmeter and an ammeter in the same manner as with direct currents.

WATTMETERS.

The wattmeter, which is therefore the most suitable means of measuring power in an alternating-current circuit, is in general a combined voltmeter and ammeter which multiplies simultaneous instantaneous values of current and voltage, and indicates or records the effective value of the result.

ALTERNATING-CURRENT POWER CURVES.

The power delivered by an alternating-current generator is illustrated in Fig. 17. Let the axis OX represent time as before, for example, the time axis of a sixty-cycle alternating current, in which case the distance OD represents one-sixtieth of a second. The OY axis represents amperes when considering the current curve OABCD, volts when considering the electromotive force curve OEBFD, and watts when considering the energy curve OMBND. The last curve is obtained from the other two by multiplying the instantaneous values of the current and electromotive force. Thus, the product of ES and AS is MS; of VW and UW, TW, and so on. The product of CP and FP, which are below the axis OX and represent negative quantities, gives the positive quantity NP. For this reason the curve representing watts lies entirely above the axis OX. This is what would be expected on first thought, for we consider the energy of a circuit as unidirectional. In this case the product of the reading of the alternating-current ammeter and that of the alternating-current voltmeter is equal to the reading of a wattmeter and is represented by the dotted line YY'. This is the case when the circuit is non-inductive, in other words, when the current and electromotive force are in phase with each other.

LAGGING CURRENT.

In an inductive circuit where the current is out of phase with the voltage it is

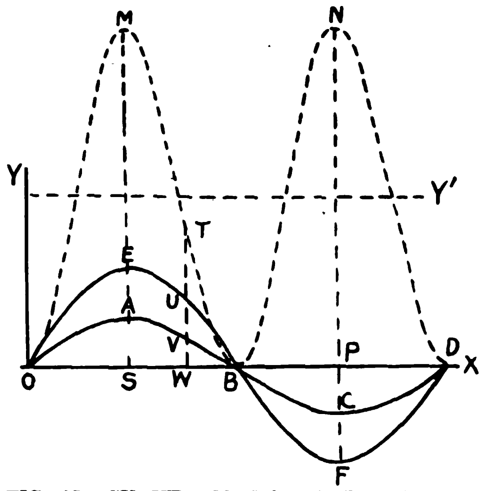

FIG. 17.—CURVES OF VOLTAGE, CURRENT AND POWER IN A CIRCUIT OF PURE RESISTANCE.

customary to speak of the current as lagging behind the electromotive force, the difference in phase being called the angle of lag. In the preceding case the angle of lag is zero, because the resistance is non-inductive. In Fig. 18, however, the angle of lag is forty-five degrees, as rep-

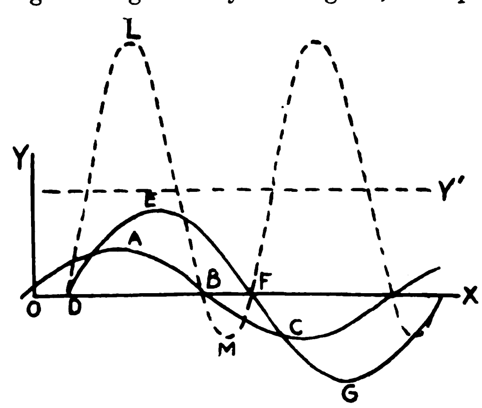

FIG. 18.—CURVES OF VOLTAGE, CURRENT AND POWER IN AN INDUCTIVE CIRCUIT OF 0.707 POWER-FACTOR.

resented by the length of the line OD. Let OABC represent the current, DEFG the electromotive force, and DLBM the energy. It is evident that these curves represent an inductive circuit. Although the current and electromotive force are drawn to the same scale as those in Fig. 17, it is will be noticed that the energy curve is not as large and the wattmeter reading represented by the height of YY' is not as great in the latter as in the former figure. Further, a part of the energy curve of Fig. 18 lies below the axis in this case. Those parts of the energy curve lying above the axis OX represent energy absorbed by the circuit to do work, while those below represent energy returned to the circuit.

POWER FACTOR.

It is an experimental fact that the energy available for use in an alternating-current circuit containing inductance is not the product of the voltmeter and ammeter reading, but is less, depending on the angle of lag. It is, in fact, equal to the product of the two by the cosine of the angle of lag, thus:

$$W = EI \cos \phi,$$

where ϕ is the angle of lag. In the case of Fig. 15, where ϕ is forty-five degrees,

$$W = 0.707\ EI.$$

In other words, the product of the ammeter and voltmeter reading, which is called the apparent watts, in this case bears the ratio of 1 to 0.707 to the reading of the wattmeter and shows the true watts. In general,

$$\frac{\text{True watts}}{\text{Apparent watts}} = \frac{EI \cos \phi}{EI} = \cos \phi.$$

$\cos \phi$ is called the power-factor. It may vary from zero to unity, being zero in the theoretical case of pure inductance in the circuit, and unity where there is no inductance, as is illustrated in Fig. 17, where ϕ is zero, hence $\cos \phi = 1$.

The practical meaning of the power-factor is that the actual power delivered to a receiving circuit is only that part of the apparent power which is represented by the fractional value of the power-factor; for example, if a 200-kilowatt generator is running at normal voltage and amperage on a circuit having a power-factor of 0.707, as above, only 141.4 kilowatts will be actually delivered, the remainder being represented by that part of the power curve below the line, which indicates the power stored in the magnetic field, like that stored in a coiled spring. It is returned to the circuit when the voltage drops to zero, just as the energy of the coiled spring is released when the tension of the spring is relieved.

[To be continued.]

Central Electric Railway Association.

The regular meeting of the Central Electric Railway Association will be held at the Lima House, Lima, Ohio, on Thursday, November 19. A number of guests from Ohio, Kentucky, Michigan and Indiana have signified their intention of being present.

The Central Electric Traffic Association will hold a meeting at the same place on November 18.

PROTECTION OF ELECTRICAL CIRCUITS FROM LIGHTNING.[1]

BY E. E. F. CREIGHTON.

The problem of the design of apparatus for the protection of electrical circuits has been entirely different from the problem affecting the design of other electrical apparatus. When we start at the factory to design a motor, generator, electric lamp or anything of that kind we know what conditions must be fulfilled; we know that we have a certain potential to produce; we want to burn so many lamps on a circuit or produce so many horsepower in motors. On the other hand, until very recently, lightning arresters were built to protect against an unknown condition on the circuit. It was well known that there were induced strokes on the circuit from the discharges of cloud, but the nature of the surges was unknown.

During the last three years very extensive measurements, starting first in the laboratory and then finally carrying the methods to the line have been made of the conditions of lightning existing on power circuits. The details of these tests are too extensive to take up in the short time at my disposal. A few brief statements of results only will be presented.

Last summer two of us spent considerable time at the Animas Power and Water Company in Colorado, where they have vicious storms practically every day during the lightning season. The frequency of cloud lightning was measured and was found to be in the neighborhood of about 1,000,000 cycles per second. The frequency of discharge from an idle line was also taken and found to be about 3,000 cycles. When power is on and an accident to an insulator happens there is a frequency of recurrence which is usually about the same as the alternations of the generators, say 120 times per second.

It is possible to predetermine the number of amperes of lightning current for every volt of abnormal potential on the line.

We have made no tests on direct strokes of lightning, because it is so very difficult to get them; they occur infrequently, and when they do occur it is best to be out of the way. Our tests were on induced strokes. Occasionally we found potentials momentarily on the line as high as many hundreds of thousands of volts, between 300,000 and 500,000 volts.

The next factor measured was the quantity of electricity in the stroke. That of course varies with every cloud and with the relative position of the cloud and the line.

The most important factor was the duration of the lightning stroke. The ordinary lightning stroke had a measured duration of about 1-100 of a second; the menace is not in the actual duration of the stroke, but in its recurrence. Numerous cases were recorded where a stroke of lightning would be followed by seven successive strokes within a second. This has been the cause of some of the failures of the multi-gap arresters.

There are many cases of high-potential surges on the line. For the present analysis these can be resolved into four conditions. The first is the direct stroke of lightning. A direct stroke of lightning very seldom hits a line; it hits a tree or a building somewhere near, and on the line there is simply an induced stroke. A direct stroke usually goes to ground within that distance. The best protection to a line that can be given against a direct stroke is to install an overhead ground wire and ground it frequently. The overhead ground wire is usually unnecessary in cities, because the same kind of protection will be given by the overhanging trees and buildings.

The second kind of a lightning stroke is the induced lightning stroke, which comes from the cloud being over the line and inducing a charge on the line. This is a problem which is quite easy to take care of and which is well taken care of at the present time by the multi-gap arrester. The multi-gap arrester in its latest improvement has four paths to ground, so that it can take care of lightning of wide ranges of frequency and quantity of electricity. The only condition in this category of lightning the multi-gap arrester cannot always take care of is that of severe multiple strokes already mentioned.

The third condition on the line, and it is the most important and the hardest one to take care of, is due to an accidentally grounded phase—for example, the breaking of an insulator so that the arc can play from the line to the pin, say, or from the line to a green branch, or from the line over the bushing of a transformer to the case which is grounded. These are the three conditions usually met.

Every time the arc jumps from the line to ground conductor, and it does it every half cycle as a rule, there is a surge set up on the other phases of the system which will tend to make them discharge through the internal windings, bushings or insulators. In so doing the surge will cause a short-circuit of the generator and an interrupted service.

It is hazardous to the internal insulation of the apparatus to allow these surges play over the system. The hazard varies greatly on different systems. On high-tension systems some apparatus is destroyed by such surges within a second. On other systems the accidental arcs have existed for hours without causing any visible damage. In this case if there is a multi-gap arrester on the circuit and its gap length is small enough to spark it will discharge during the first surge. It puts out its own dynamic arc at the end of the half cycle of the generator wave, but again the generator potential rises in the opposite direction and starts the accidental arc again; the surge is re-established on the circuit again and the multi-gap arrester discharges. Now, the multi-gap arrester cannot be designed to carry the current continuously at any reasonable commercial cost; consequently, under these continuous surges the multi-gap arrester must necessarily be destroyed. The only lightning arrester that can take care of continuous surges is the aluminum arrester. Of that I will speak later.

The fourth condition requiring protection is one that has come up recently. It seems to occur mostly on motor circuits—for example, in a large building fed by direct current, where electric motors for elevators and other purposes are operated. If the load on that building becomes so great that a fuse blows, then the circuit of the building is disconnected from the main circuit, with the meter on the isolated side. Sometimes the motor fields discharge and raise the potential to such a high value as to destroy the meter. It is evident that if a heavy current is flowing through a motor and the circuit is suddenly broken the conditions are exactly the same thing as in an induction coil. The value of voltage from the electromagnetic kick depends on how quickly the arc is broken and how quickly the magnetism changes. The protection for this surge of potential is a direct-current type aluminum arrester.

Recapitulating, four kinds of lightning

[1] An address delivered before the Ohio Electric Light Association at Put-in-Bay, August 26, 1908. The author is assistant professor in electrical engineering at Union University, Schenectady, N. Y. His investigation of lightning phenomena under the leadership of Dr. C. P. Steinmetz has attracted wide attention. While an abstract of this address appeared in a recent issue of the Electrical Review, the present treatment is more comprehensive and was revised by Mr. Creighton for the Western Electrician.

potentials or surges that have to be met are: First, a direct stroke of lightning; second, an induced stroke from a cloud; third, an accidentally grounded phase, and fourth, the inductive kick from a direct-current motor circuit.

Just a few words about the aluminum arrester and the principle of its action. There are two forms now on the market, one for alternating current and the other for direct current. The alternating-current aluminum arrester consists of a series of cells made up of inverted cones, one setting inside of the other and separated by small fiber washers. The space between these cones is about half filled with electrolyte of good conductivity, then the whole mass is immersed in a tank of oil. The oil acts beneficially in two ways; first, it insulates the parts not immersed in the electrolyte; and second, it cools the cell so that the arrester may operate for a long time. The arrester being made up of multiple cells, its characteristics are the same as the characteristics of a single cell. The number of cells in an arrester is found by dividing the voltage by 300 volts.

The characteristic action of an aluminum cell is very similar to a lead storage battery on a direct-current system. If a storage battery floats on a 600-volt system, say, the battery will take the current until the voltage per cell rises to about 2.2 or 2.5 volts. At that time the current in the battery is reduced to almost nil by the counter electromotive force. However, if the voltage on the circuit is carried above 600 volts, a heavy dynamic current will flow through the battery. The value of this current will be found by dividing the excess voltage by the internal resistance of the battery. If the resistance of the battery is one-half ohm, there will be two amperes of current for every volt above 600, but no current at 600 volts. Thus a storage battery on a direct-current circuit is one of the best kind of lightning arresters for discharging low-frequency surges because it holds back the dynamic current and allows only the excess voltage to discharge through it.

An aluminum arrester acts very similarly. The aluminum plate is carried through a chemical process by which a film of microscopic thickness is formed on the surface. It is shown on the surface as an iridescent color, or a slight whitish appearance. This film bears much the same relation to the circuit as the counter-electromotive force does in the battery. Take two cells on a 600-volt, direct-current circuit, for example, the leakage of current will be about 0.001 of an ampere, but for every volt of pressure above 600 the cells will allow current to flow through them equal to the excess voltage, divided by the resistance of the electrolyte. Since the resistance is about one-half ohm, you can see that means about two amperes for every volt excess. By the time double voltage is reached over 1,000 amperes are flowing through that cell.

The aluminum cell acts just like a safety valve on a steam boiler. At normal pressure there is practically no discharge, but at abnormal pressure the electric valves open up—there are myriads of them on the surface of this aluminum plate—allowing the electricity to flow through. In a direct-current cell the ratio of the current between normal potential and double potential is about 1,000,000; in other words, the current increases from 0.001 ampere to 1,000 amperes.

There is still one important precaution to take when making the installation of these arresters: Make the arrester circuit as short and of as low inductance as possible, or the arrester will be ineffective for very high frequency discharges.

In the alternating-current lightning arresters made for voltages from 2,300 to 110,000 volts, a gap is placed in series, in order to prevent the wearing of the plates by the constant action of the alternating current. The alternating current wears the plates very much more rapidly than the direct current.

These alternating-current lightning arresters are designed to carry a discharge continuously for half an hour. If an accidental ground, due to a broken insulator or other cause, takes place and sets up continual surges, it is estimated that in a half hour the trouble may be removed. This may be done, first, by switching to an auxiliary line; second, by sending a man out to the trouble; third, by putting a metallic ground connection to the affected phase. It is the arc between the phase wire and ground that causes the surges of potential. The phase that is grounded can usually be located by looking at the lightning arresters. Of the three phases, the gap that does not arc is connected to the wire upon which the trouble exists.

In conclusion I wish to state what has been accomplished with these lightning arresters. The cone lightning arrester has been in operation for a number of years. The most conclusive experience has been obtained by the installation on the Animas Power and Water Company's line in Colorado, where they have eleven aluminum arresters. During the month of July last year, they had about ten storms, and twenty-two interruptions of service. I cannot give you, offhand, exact figures, but only approximate. This year, with the arresters on the circuit at nearly every station, they had eighteen storms, and no interruptions of service. They had one interruption of service during the month, which occurred at a station where they had no protection. They have thirty stations to protect there, and they did not have time to get all the arresters in. This one interruption at that time cannot be attributed to the lightning arresters.

In conclusion, the state of lightning arresters, as now designed, is such that we can predetermine beforehand just exactly what the lightning arrester will do. The discharge rate is tested by applying dynamic voltage. The characteristics of the usual lightning discharge have been measured and the arresters given a large margin of safety to meet the requirement. The records of what an arrester will do are available, the same as for motors of standard make.

Electricity in Japan.

Vice-Consul E. G. Babbitt, of Yokohama, transmits an article from a local newspaper on the development of the electric industry of Japan from which the following resume has been made:

"The authorized capital of electric undertakings in 1903, 28,500,000 yen ($14,193,000), of which 24,000,000 yen ($11,952,000) was paid up, had risen to 138,000,000 yen ($68,724,000) in 1907, of which 87,500,000 yen ($43,575,000) was paid up. The electric works undertaken chiefly represented lighting and tramways. The number of lights supplied in 1903, 365,000, had increased in 1907 to 859,143. Tokyo and Osaka require each 100,000 lights. Electric tramways show equal development. In 1903 the mileage was thirty-eight, which rose to 119 in 1907, and will be largely added to by construction during the present year."

After reciting the foregoing progressive electric undertakings the newspaper article concludes as follows: "It is to be specially noted that while the works have been making steady progress not a few of the companies are in serious financial straits."

Electrical Notes from Great Britain.

[From our British Correspondent.]

Beyond all possibility of doubt, when reviewers come to sum up the electrical doings of 1908 in the United Kingdom, they will describe the Manchester Electrical Exhibition, just closing, as the most important event of the year. With the great masses of the industrial workers interested in the very extensive textile and engineering industries of the Manchester and Lancashire districts, the show has been extremely popular; indeed, on Saturday afternoons and evenings, when these have put aside their factory and works attire, the too-small gangways in the exhibition hall have been filled to overflowing by large numbers of such employes who are not only interested in, but are anxious to be instructed in, the applications of electric power to the classes of machinery with which they are in everyday touch. This point is emphasized because the power side of the exhibition is by a long way its strongest. With the stimulation that the last year or two has given to electrical installation work in textile factories, it is but natural that a number of exhibits of electrically-driven looms and other machines of the same class should be of particular interest to the mill employe. Other motor applications include a goodly number of machine tools electrically driven. In the matter of power plant of fair size, the exhibition is very satisfactory, for there are a number of turbo-generator examples, including the Musgrave-Zoelly, the Howden-Zoelly, and the British Thomson-Houston Curtis vertical and horizontal types; other prime movers present are a British Westinghouse gas engine (150 horsepower), a Diesel oil engine by Mirrlees, Bickerton & Day, and steam and gas-driven sets of various makes, including a Crossley suction gas plant and engines. An electrically-operated hammer, numerous motor-driven pumps, and many other things might be enumerated to emphasize the importance of the show as a demonstration of modern electric-power generation and utilization, were it necessary.

The exhibition has, however also been affording, not only the Manchester man, but also all electrical engineers and traders who have been going into Manchester from near and from far, an excellent opportunity for seeing an admirable and varied display of the newest forms of electric lamps. Owing to the lack of natural illumination in the hall, a splendid opportunity was given to all the lamp makers to give very lengthy displays. The names hardly require stating here, but all the usual and well-known incandescent, carbon, metallic-filament, flame, and other lamps are shown—some of them very attractively, and altogether a striking effect was produced.

The substation supplying energy for lighting the buildings and supplying the wants of power users in all parts of the hall, occupied a central position and was an open affair, so that the spectator might see the installation at work, taking the high-pressure, 6,500-volt, three-phase current from the Corporation Stuart Street generating station and reducing and converting it for a 230-volt lighting system, and to 400 to 500 volts direct current for power. A 700-kilowatt Westinghouse rotary converter and an 800-kilowatt, three-phase, static transformer for same; a 600-kilowatt Bruce-Peebles three-bearing-type motor-converter; a 500-kilowatt General Electric two-bearing-type, induction motor-generator (each set being arranged for three-wire balancing), were serving for direct-current purposes. For alternating-current service there were three Westinghouse static transformers.

It goes without saying that no such impressive and educational exhibition could be held in the heart of an industrial district with so many power-driven textile and other factories not yet changed over to electricity, or with such large numbers of the gas-using resident, without the business of electricity supply and of electrical machinery supply being greatly benefited.

That there is a need for benefit of this kind to be brought to some departments of the industry at the present time appears from various signs, including some remarks offered by Mark Robinson to shareholders of Willans & Robinson, Limited, turbine makers. The Rugby company, whose experiences leading up to the development of the Willans turbine business have already been related in the ELECTRICAL REVIEW, complains that the times are very difficult and that the future is hard to foresee. Demand is small, competition is great, profits are cut to the lowest point. The company's best customers were the municipalities, and these, said Mr. Robinson, were restricting their enterprises, partly in deference to a public feeling which was widely spread, but partly, also, as regarded electric lighting, owing to the introduction of the metallic-filament lamp, which used so much less current than the old carbon lamps. Reduced cost to the consumer would doubtless be followed by a great extension of electric lighting, when more plant than ever would be wanted, but "for the present there was an undoubted check" upon the steam-turbine manufacturing business.

Turning now to the speech of John Kerr to shareholders in Dick, Kerr & Co., Limited, one of the foremost and most successful electrical-plant manufacturers and tramway contracting concerns in the United Kingdom, we find some further observations concerning the prevailing state of things industrially. The keen competition of the past two years has, according to Mr. Kerr, become accentuated, and he cannot see much likelihood of it becoming less keen. In addition to severe trading competition, the financial crisis in America had had its effect all over the world, making investors hesitate to enter into new enterprises. Further, owing to the financial crisis and the high bank rate, municipal borrowing had been considerably restricted. This, in view of the fact that the company was largely dependent upon the municipalities for one particular branch of its business, had had a serious effect upon its turnover. As the result of all this the company was devoting most of its energies to developing colonial and foreign electrical business, and a very large proportion of the machinery then under course of manufacture at its works at Preston was for abroad.

Having felt the transportation pulse of one of its districts for a sufficient time by means of motor omnibuses, the Municipal Corporation of Wolverhampton has arrived at the conclusion that a tramway is warranted, and it is going to lay down the Lorain surface-contact system (Lea Road and Penn Fields District) at a cost of something over $100,000. Coming at a time when surface-contact traction is not having things by any means all its own way, this decision is at least noteworthy, though the Wolverhampton Corporation has all its existing lines equipped on the Lorain principle. Folkestone, Sandgate and Hythe are three contiguous attractive seaside resorts on the southeast coast which have been the scene of endless controversy as to systems of electric traction. The National Electric Construction Company is interested in the proposed scheme, and it is reported that it is wanting to change over from its original idea of using the Dolter surface-contact system and employ instead the overhead trolley. The company, as was announced some months ago, had to take out its Dolter track at Musselburgh and resort to overhead-trolley equipment. There may, however, be more difficulty in securing the necessary local sanction for overhead wires in such a district as Folkestone or in Sandgate. Earl Radnor, the lord of the manor, who is the owner of the greater part of Folkestone, has resisted most strenuously hitherto any attempt to introduce overhead wires for tramways. That seems to be the reason why these popular places have to be so long without sufficient transportation accommodation for the vast multitudes of visitors who find their way there for holidays in the course of a year.

The "C. B." surface-contact system is being employed for some miles of track at Lincoln, as already stated. It is now said that tramway extensions costing between $100,000 and $125,000 are to be taken in hand there.

The Liverpool City Council may shortly decide to run cars on an electric trackless-trolley system to Broad Green Road.

The last few weeks have witnessed the reopening of many of the engineering and scientific societies after the summer vacation. J. E. Darbishire opened up for discussion at the Institution of Mechanical Engineers, in London, a subject whose importance is becoming increasingly recognized in recent years, namely, the repairs, renewals, deterioration and depreciation of plant and machinery. He remarked that in the systematization of the management details of an engineering establishment which had been a feature of recent years, the method of dealing with the wear and tear, repair and renewal, and depreciation of plant and machinery had strangely escaped attention. There seemed to be as many different ways of treating the question as there were engineers or accountants.

The Association of Engineers-in-Charge, a useful society of practical men which has grown in popularity during the last year or two, opened on October 14 with an address on "Smoke" by its president, James Swinburne. On the same evening, at University College, Prof. J. A. Fleming delivered a lecture, introducing a special course on the scientific principles of radio-telegraphy and radio-telephony. The Physical Society of London commenced with a visit to the National Physical Laboratory to witness a series of demonstrations of work in progress there. On October 15, A. F. Bennett discoursed on "Steam Engineering Progress" before the Rugby Engineering Society, whose membership consists largely of members of the staff of the British Thomson-Houston Company and Willans & Robinson, at Rugby, and of which society he is this session's president.

The arrangements of the Institution of Electrical Engineers for London meetings are not yet announced, but the Manchester section has got to work, Miles Walker, the chairman, delivering his address on October 23.

The Cleveland and Durham Electric Power Company has agreed with the Waste Heat and Gas Electrical Generating Stations Company to operate power stations erected by the latter company, at the works of the Weardale Steel, Coal and Coke Company at Tudhoe, Spennymoor, and of Sir Bernard Samuelson & Co., Newport, Middlesborough. Arrangements have also been made for supplying four new rolling mills that are under construction in the Cleveland district. There is now 20,105 horsepower connected with the system, as compared with 9,172 horsepower a year ago. A further 8,850 horsepower will be connected up shortly. In referring to this company's business, it will be fitting to mention that on October 3 many mining engineers journeyed to the works of Ernest Scott & Mountain, Limited, at Gateshead, to inspect a large main and tail haulage plant which is to go into the Loftus mines of Pease & Partners, to be driven by three-phase current obtained from the Cleveland Power Company's mains. The haulage gear has two drums six feet in diameter and thirty-two inches wide, running loose on an 11-inch diameter shaft between two bearings; a third bearing carrying the outer end of a shaft supporting the large spur wheel which is keyed to the drum shaft and is driven through double-reduction gearing by a 350-horsepower slip-ring, three-phase motor, designed for 2,750 volts and forty cycles. It runs at 345 revolutions per minute, and the rope speed of the drums is nine miles per hour. A further 350-horsepower, three-phase motor is being put in to drive an existing haulage by rope gearing.

The London electric power question has again been engaging the attention of politicians at Westminster. A debate on the London and District Electricity Supply Bill, which received so much attention some months ago, and was awaiting the further deliberation of another parliamentary committee, took place on October 19, when, by a majority, it was decided to insert in the bill a clause granting purchase powers for the undertaking to the London County Council, who may thus, in course of time, become the electric-power-supply authority for not only London, but a good many other places outside it as well. There was stout resistance offered on behalf of London and outside municipal authorities who have their own generating and distributing systems already, but, as stated, the result was the declaration of a principle in favor of ultimate London County Council control. The bill has farther to go yet before it will be out of the wood, and probably when it has passed all parliamentary stages it may have its greatest difficulty in getting the public to subscribe the capital it requires, at a reasonable price and at a low rate of interest.

ALBERT H. BRIDGE.

London, October 28.

Alabama Lighting and Traction Association Formed.

About thirty representatives from various cities of Alabama met at Montgomery and formed the Alabama Lighting and Traction Association. The call was extended by A. H. Ford, president of the Birmingham Railway, Light and Power Company, who was elected temporary chairman of the association. The purpose of the association is set forth to be to benefit the electric, gas and traction properties of the state, and the meetings will be addressed by members and others on technical subjects of value to the association. At a meeting to be held within a month the permanent organization will be effected and officers elected. F. K. Jackson of Mobile was made temporary secretary and treasurer.

MODERN SUBSTATION APPARATUS.[1]

BY E. W. ALLEN.

It is the purpose of this paper to list several sizes of synchronous converters, synchronous and induction-motor-driven, low-voltage direct-current generators, and compare their relative advantages and disadvantages with the object of determining which of the three types is best suited to the conditions usually found in sub-stations supplying direct current to a 125-250-volt three-wire bus and receiving current, first from a 6,600-volt, three-phase, twenty-five-cycle generating station, and second, from a generating station having the same type of generators but a frequency of sixty cycles per second.

SYNCHRONOUS CONVERTERS.

The synchronous converters, or, as they are more commonly termed, rotary converters, are equipped with regulating poles capable of giving a range of from 240 to 300 in the direct-current voltage. This means of controlling the direct-current voltage is radically different from anything heretofore employed and represents the latest advance in the art of manufacturing this particular class of apparatus. In any synchronous converter the direct-current voltage has a definite value or ratio with respect to the alternating current voltage impressed upon the collector rings, which can be varied within certain limits by changing the width of the pole arc. The function of the regulating pole is to vary the width of this arc, and hence the ratio of alternating to direct-current electromotive force by assisting or opposing the flux in the main pole. In other respects the converters are similar to standard machines. Three-phase air-blast transformers have been used in compiling these figures. The primary windings are provided with four two-and-one-half per cent taps, and the secondary windings are so arranged that a connection can be made for the neutral of a three-wire system.

SYNCHRONOUS MOTOR-GENERATOR SETS.

The motor-generator sets consist of a synchronous motor mounted on a common base, with and direct-connected to a commutating-pole shunt-wound generator. The motors are designed to operate at eighty per cent leading power factor, so there is available in each machine, in addition to sufficient capacity to drive its generator at full output, a margin of sixty per cent of its rated capacity for phase control. An amortisseur winding is placed over the revolving field to assist in starting and to relieve any tendency on the part of the motor to pulsate. The field winding of the motor is designed for excitation at 125 volts, and if current at this voltage is not available, exciters should preferably be direct connected to the sets. Their cost, however, is not included in the prices listed, and the cost of the complete set with exciter is from four to six per cent greater than the figures given in the table. The current output of the generators is based on 275 volts, but they will commutate this current successfully at any voltage between 240 and 300 volts.

INDUCTION MOTOR-GENERATOR SETS.

The induction motor-generator sets are in general similar to the synchronous motor-generator sets. The rotors of the induction machines are equipped with a definite three-phase, star-connected winding, the open end of each phase being connected to a collector ring mounted on the end of the shaft. An external resistance is placed in series with this winding to limit the flow of current and increase the torque when the motor is started. This resistance is short-circuited in successive steps by means of a controller, the last step being short-circuited when the motor reaches full speed. The generators are duplicates of those forming part of the synchronous motor sets previously described.

COMPARATIVE VALUES.

The synchronous motor-generator set has been selected as a basis for the comparisons made in Table I. The values for the synchronous converters and induction motor sets are expressed in percentage of the corresponding values in the synchronous motor set. The sign preceding a figure denotes whether it should be added or subtracted from the figure given on the synchronous motor.

EFFICIENCY.

An analysis of the figures given in Table I will show that the twenty-five and sixty-cycle synchronous converters are superior in efficiency at all loads to either type of motor-generator set, the difference being particularly marked at light load on the twenty-five-cycle machine. The brush friction and windage constitute a relatively larger proportion of the losses in the sixty-cycle converter, and its efficiency

[1] Abstract of a paper read before the Association of Edison Illuminating Companies, Lenox, Mass., September 15-17.

at light load only exceeds that of the motor-generator set by a small amount. The induction motor set is more efficient than the synchronous motor set at twenty-five cycles but less efficient at sixty cycles.

PRICE PER KILOWATT.

With the single exception of the 2,000-kilowatt, twenty-five-cycle unit, the synchronous converters are less expensive in both frequencies than the motor-generator sets. In the larger sizes the twenty-five cycle induction motor sets are less expensive than either of the synchronous machines. The high cost of the 300-kilowatt, twenty-five-cycle induction-motor set is due to the external starting devices which constitute a relatively large proportion of the cost of the motor. The sixty-cycle synchronous motor-generator sets are less expensive in all sizes than the induction machines listed at this frequency.

WEIGHTS.

The weight of the motor-generator sets is, owing to the high speed, slightly less than that of the synchronous converters, with its accessories, the induction motor weighing less in both frequencies than the synchronous-motor set.

RELIABILITY.

Advocates of the induction motor anticipate trouble from "hunting" of the synchronous machines, but the cause of this trouble is a condition of the line or system to which the synchronous machine is connected, and can usually be found and overcome. Wide fluctuation in the voltage of the alternating-current supply has also been assigned as a source of trouble with the synchronous machines, but there is no very good reason why such conditions should exist, as the regulation of the supply voltage can be controlled within narrow limits by the judicious use of an automatic voltage regulator arranged to control the excitation of the generators in the main station. The excellent protection afforded by the use of speed-limiting devices, reverse-current relays and circuit-breakers practically eliminates the possibility of damage due to runaways or overloads.

VOLTAGE REGULATION.

Voltage regulation over wide ranges is a matter of great importance in the class of sub-stations considered by this paper. Edison three-wire systems require a range in voltage of at least 240 to 275 volts, and in many cases a considerably higher voltage than the last-named figure is required for charging storage batteries. Excellent results have in the past been obtained from shunt-wound generators, but it has been found necessary to add a large amount of extra shunt field copper and magnetic material to secure good operation over this range in voltage. The addition of commutating poles has made it possible to operate high-speed generators with excellent commutation at voltages considerably below normal, but they do not assist materially in reaching the higher ranges. It is the usual practice to base the current output on the highest voltage, and it has not been practicable to obtain appreciably higher voltages, even though the output was kept constant by a reduction of the current in proportion to the increase in voltage. With the synchronous converter equipped with regulating poles it is possible to obtain a wide range in voltage without materially increasing the cost over that required to give a lower range.

The excitation of a regulating-pole converter can be controlled by means of an automatic regulator, and the direct-current voltage kept constant even with wide variations in the voltage of the alternating-current supply. The regulator may also be adjusted to hold a constant load on the converter and cause storage batteries or other machines to carry fluctuations in the load beyond a predetermined amount.

PHASE CONTROL.

The synchronous motor-generator set is the logical choice for installation on a system carrying a low-power-factor load, as extra capacity for improving the power factor can be furnished at a small increase in the first cost. For example, a 1,250-kilovolt-ampere motor will drive at full output a 1,000-kilowatt generator and in addition deliver to the line 750 kilovolt-amperes for improving the power factor.

METHOD OF STARTING.

Storage batteries are installed in the majority of lighting sub-stations, and direct-current starting is to be recommended in such cases for all three classes of machines. If direct current cannot be obtained from such a source, a failure of the alternating-current supply will cause a complete shutdown of the sub-station and require the starting of at least one unit from the alternating-current side, after which direct current will be available for starting the remaining units. All of the machines described in this paper are admirably adapted for starting from the alternating-current side. The resistance in the secondary circuits of the induction machines limits the flow of current at starting to a value considerably less than that required at full load. Synchronous motors are started by means of starting compensators connected between the motor terminals and the line. Synchronous converters can be started from one-third and two-thirds taps on the secondary of their transformers. When motors are started in this manner it is not necessary to synchronize them with the line; consequently the machines may be very quickly started from rest and placed under load. Alternating-current starting motors possess a number of disadvantages without offering any particular advantages over the methods of starting described above and their use is not recommended.

Electric Scrubber for Ships' Hulls.

Many devices have been invented to clean a ship's fouled bottom without the necessity for docking, and perhaps the most effective of these was the old-fashioned hogging brush with which the submerged parts of the hull were scrubbed, but difficulty was always experienced in applying sufficient force to the brushes, writes the English correspondent of the *Scientific American*. Electromagnets mounted on the brush battens hold the bristles firmly against the iron or steel hull of the ship while the "mat" or gang of brushes is being dragged over the surface. The brushes are set at an angle on the principal working battens, while other brushes set square precede the magnet poles, affording them a clean surface on the hull to which to adhere. The pole pieces are rocker-shaped, being arranged to cant the brushes to secure a flicking action against the accumulated matter. The current to excite the adhesion magnets is supplied either from the ship itself or a special tender lying alongside, and the entire mat is dragged back and forth across the bottom of the hull by a steam winch. A tractive effort of about 3,000 pounds is required to drag the mat against the resistance interposed by the marine material and friction at the pole pieces. The gear is very simple, and several men from the ship's crew can clean a 4,000-ton ship in eight hours at an expense of $100, including cost of labor, current and power. An 18,000-ton battleship can be cleaned in twelve hours, it is said, and vessels scrubbed by this method are found to be entirely free from marine growths when examined in dry dock.

Some Large Telephone Cables.

A number of large telephone cables were made recently by the well-known cable manufacturers, British Insulated & Helsby Cables, Ltd. Fig. 1 shows an 800-pair cable made of such a size that it can be drawn into a standard three-inch pipe. Several miles of this cable are in use by the National Telephone Company of England and various colonial and foreign administrations. The conductors weigh ten pounds per mile. Each is insulated by a single layer of manila paper, applied spirally; the longitudinal method of wrapping with a whipping of thread is only employed for wires of forty pounds per mile and upward.

In the earlier telephone cables, says *Electrical Engineering* (London), two layers of paper were almost invariably employed, but it is now found that the single layer is sufficiently strong mechanically, and that, owing to the tighter laying up of the wires that is necessary if the thickness is increased by the second layer of paper, and the fact that the specific inductive capacity of paper is higher than that of air, the cable with the single layer of paper on each wire has a lower capacity and is therefore better for telephonic purposes, in addition to being cheaper.

The paper-insulated wires are laid up into pairs and then stranded, the center core having five pairs and each successive layer six more pairs than the previous one. The lead sheath is 125 mils in thickness, bringing the outside diameter and the whole cable to 2.625 inches. An average wire-to-wire capacity of 0.07 microfarad per mile is obtained and a maximum of 0.08 microfarad per mile. This is extremely low when it is considered how close the wires must be packed to enable 1,600 of them to be contained in a 2⅝-inch lead tube. The cable is usually supplied in lengths of 150 to 200 yards; its weight is about twenty tons per mile.

In Fig. 2 there is shown a section of a composite telegraph and telephone cable of a type referred to by Mr. F. Tremain in an instructive paper read before the Newcastle Local Section of the Institution of Electrical Engineers. Considerable quantities of this cable are in use by the British Post Office on its underground routes.

The cable contains fifteen pairs of 150-pound twin conductors, seven quadruple pairs of eight conductors, each weighing 100 pounds per mile, six pairs of 100-pound conductors; twenty-two single "screened" conductors weighing 200 pounds per mile, for telegraph purposes, and forty-two single-screened seventy-pound conductors—162 wires in all.

The telephone wires in the pairs and "quads" are insulated with manila paper, applied longitudinally, and secured by a whipping of string. A similar longitudinal paper forms the first wrapping of the screened telegraph conductors, but in this case it is covered with three more paper wrappings, laid spirally. The first two of the spiral wrappings are laid on so as to leave a helical air space, and the third forms a closed helix. Over this is a wrapping of copper tape three mils thick and three-eighths inch wide, with a thirty per cent overlap. The copper screening is to prevent inductive action between neighboring wires.

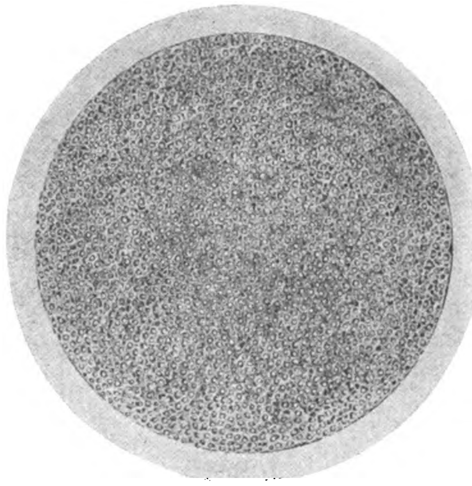

Fig. 1.—Eight-Hundred-Pair Lead-Covered Telephone Cable, Outside Diameter Two and One-quarter Inches.

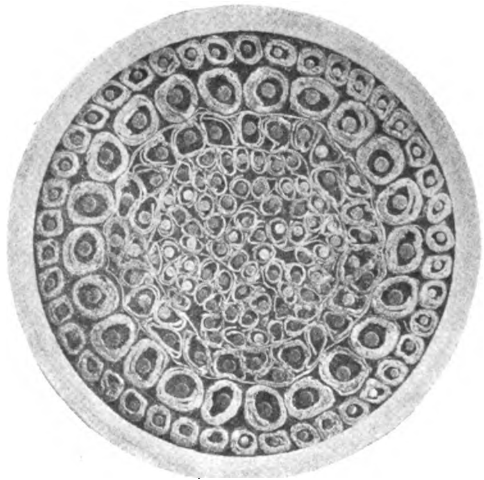

Fig. 2.—A Composite Telegraph and Telephone Cable Used by the British Post Office. Outside Diameter, Three and Three-quarter Inches.

The center core consists of one quad—four pairs of conductors laid round a jute core. Surrounding this are six more similar quadruple pairs. The interstices left between these six quads are filled up by the six ordinary pairs of 100-pound conductors as a "worming," making this layer circular. Over this comes a layer of twenty-two 200-pound single-screened conductors (each 350 mils diameter over all), and the outside layer is made up of the forty-two 70-pound single-screened conductors (each 225 mils diameter overall). The screened conductors have a capacity of about 0.125 microfarad per mile; the capacities of the seventy-pound and 200-pound conductors are practically the same, as the larger diameter of the latter is compensated by the greater distance between the wire and the screening. The 100-pound telephone conductors have an average wire-to-wire capacity of 0.08 microfarad per mile, and the 150-pound pairs 0.06 microfarad per mile.

It should be mentioned that the "wire-to wire" capacities quoted in this article represent the capacity between the two wires of a pair, assuming both to be insulated. The capacity of each wire, if its fellow is connected to the remaining wires and grounded, to form the second plate of the condenser, is, roughly, forty per cent higher.

As an additional precaution to prevent inductive effects between adjacent pairs of telephone wires, each of the four pairs of each quad is given a different "lay," varying from seven to twelve inches, and in laying up the pairs into the quadruple core a different lay, varying from twelve to eighteen inches, is taken in making each "quad." The lead sheathing is 160 mils thick, and the outside diameter over lead 3¾ inches, so that the cable can be drawn into a four-inch pipe. The cable weighs about thirty-four tons per mile, and is made in lengths of about 150 yards.

Annual Dinner of the Institution of Electrical Engineers of Great Britain.

On October 22 the Institution of Electrical Engineers of Great Britain held its annual dinner at the Hotel Cecil, London. About 400 members and guests filled the banquet hall to the utmost. The gathering was exceptionally brilliant, due to the presence of delegates from all the foremost nations of the world to the International Conference on Electrical Units and Standards and the International Electrotechnical Commission. Among the speakers were Hon. R. B. Haldane, Lord Alverstone, Prof. J. J. Thomson, Mr. G. Franklin, Prof. Sylvanus Thompson, Dr. E. Warburg, M. P. Boucheret, Dr. E. W. Stratton, Prof. G. Kapp and Mr. W. M. Mordey, president of the institution.

"Pioneer Work within the General Electric Company."

At Schenectady, October 29, about 400 members of the local section of the A. I. E. E. listened to a very interesting and instructive paper by Dr. E. W. Rice, Jr., vice-president of the General Electric Company, on "Pioneer Work within the General Electric Company." An abstract of his remarks is given below.

In introducing the speaker, the chairman, Mr. Ernest J. Berg, observed that at all times the names of four men will be conspicuous in the history of the Company—the founders, Prof. Elihu Thomson and Thomas A. Edison, for their researches and inventions, and to the same degree, the president, Mr. Coffin, whose executive ability is largely responsible for the prominent part the Company fills in the manufacturing world, and last, but, indeed, not the least, Dr. E. W. Rice, Jr., the speaker of the evening, who has been in a great measure responsible for the sound engineering and thorough manufacturing and business methods which have characterized even details.

Doctor Rice outlined the history of the organization from 1880 to 1885, and told how the present General Electric Company was formed by a consolidation of the Thomson-Houston and the Edison General Electric companies, each of which had resulted from the consolidation of a number of small companies. One of these, the American Electric Company, was formed to manufacture the electrical inventions of Profs. Elihu Thomson and Edwin J. Houston, of Philadelphia, and the speaker was connected with this company since its formation.

At that time the most prominent workers in the electrical field were Charles F. Brush, Edward Weston, Thomas A. Edison, William Hochausen and Hiram Maxim. Edison had just announced his invention of the incandescent lamp. In view of its low "light efficiency" (four watts per candle compared with one-half watt per candle in the case of the arc lamp), and especially on account of the large amount of copper necessary in 100-volt distribution, it was thought by those exploiting arc lighting that incandescent-lamp illumination would never be a formidable competitor of the arc lamp.

Excepting Edison, the rest of the inventors were working on arc lighting and had their own arc dynamos, lamps and "systems." The lamps were divided into two classes, one known as the "long arc" and the other as the "short arc." Brush was the exponent of the long-arc system, Weston of the short arc. In 1880 Brush had already succeeded in producing an arc dynamo capable of operating sixteen arc lamps on one circuit. These lamps consumed about ten "Webers" (amperes) at forty-five volts, whereas the current consumed by the "short arc" was from eighteen to twenty amperes at thirty volts. Since with the latter type a large percentage of the light came from the incandescent carbon and not from the arc itself, it is evident that the efficiency of the "short arc" was not favorable compared with that of the "long arc." The Brush machine can be considered as the prototype of the modern two-phase machine, whereas the Thomson-Houston machine was practically the present three-phase machine. In each type, of course, the coils were connected to commutator segments instead of to collector rings.

Professor Thomson invented many forms of arc lamps, but the type finally selected and sold in the early days was the "differential," which had series and shunt windings placed on separate magnets in distinction to the Brush lamp, where the series and shunt windings were on the same core.

Even in those days Professor Thomson realized that it was essential to work for high efficiency, and that therefore no artificial load should be used for the sake of regulation. The dynamo must be so made that the lamps would be stable and satisfactory, independent of the number in circuit. To accomplish this result he invented a very ingenious automatic regulator, and designed his machine in such a way that the armature reaction was very great compared with the magnetization of the field.

The first arc machine built at New Britain in 1880 was capable of operating four arc lamps, these lamps using about ten amperes at fifty-five volts. After that a number of larger machines were built and no serious difficulties were met with until it was attempted to operate from sixteen to twenty lamps from one commutator, an operation which was commercially necessary since the Brush machine operated with that number of lights.

After building a successful machine with two commutators Professor Thomson decided that this was too complicated and started serious work to overcome the flashing due to the greater lead. At the time of this effort he invented an ingenious blower arrangement which injected a stream of cool air between the brush and the leaving segment. By this expedient the machine operated quite as satisfactorily with twenty lamps as formerly with ten. The machine was commercial in every way and operated even with as many as fifty and sixty arc lamps from a single commutator.

The Paris Congress, which met in 1881, adopted the "C. G. S." system and confirmed the use of the electrical units "volt" and "ohm." It also gave the name of "ampere" to the unit of current, which had previously been known as the "Weber." The ampere meter, or ammeter, was not known until some time in 1882 or 1883. Professor Thomson constructed, about 1880, an instrument on the lines of the Deprez galvanometer, which on account of its mechanical construction was usually referred to as the "herring-bone" galvanometer. The instrument was calibrated by the silver and copper voltameter method.

Insulated copper wire could be bought at that time, but the quality and uniformity of cross section was not such as to insure uniformity of resistance. Double cotton-covered wire was not used until several years later.

Transmission circuits up to 1882 were of bare copper wire, and it was customary to fasten these copper wires to partitions and rafters by means of ordinary iron staples. It was considered quite an advance when porcelain insulators first were employed. Insulated wires were considered a real extravagance and only used after demanded by the underwriters of the mutual fire insurance companies of New England.

While it was known that dynamo-electric machines were reversible no regular commercial application of the principle was made until several years later. The pattern shop of the American Electric Company was, however, operated in 1880 by a five-light arc dynamo used as a motor and the current to operate this motor was furnished by an arc-light series dynamo driven from the main engine.

The efficiency of the electrical apparatus was considered of quite as much importance in those days as now, and Professor Thomson devised an ingenious method to determine the losses. He realized in 1880 quite fully the principles governing the distribution of magnetic flux in iron, although there were, of course, at the time no standard saturation curves or permeability curves available. It was perfectly well understood that the electromotive force of a dynamo was proportionate to the speed, the number of turns in the armature and the amount of magnetic flux.

It was recognized that the iron core of an armature traversed by an alternating magnetic flux was subject to Foucault or eddy currents, and precautions were taken to use oxidized iron and frequently insulated layers of iron wire in the armature structure. Laminated iron was not introduced until later.

About 1883 to 1884 arc-light circuits had been extended enough to attract the attention of lightning and a few burn-outs of lamps were experienced. This disturbed the commercial staff of the Company, but Professor Thomson had soon devised a scheme to protect apparatus against lightning. In connection with his work on various kinds of lightning arresters he invented the "magnetic blowout."

Professor Thomson had early realized the importance of alternating current, and indeed had built a self-exciting alternator in 1879. He saw the inherent possibilities of the transformer, which at that time was called an induction coil, but he did not immediately push its use, since he felt that there would always be a certain danger if the low-potential winding were accidentally connected to the high-potential side. To overcome this he invented the grounding shield and advised a grounded secondary system. A number of patents on alternating-current distribution by transformers were issued to him about that time.

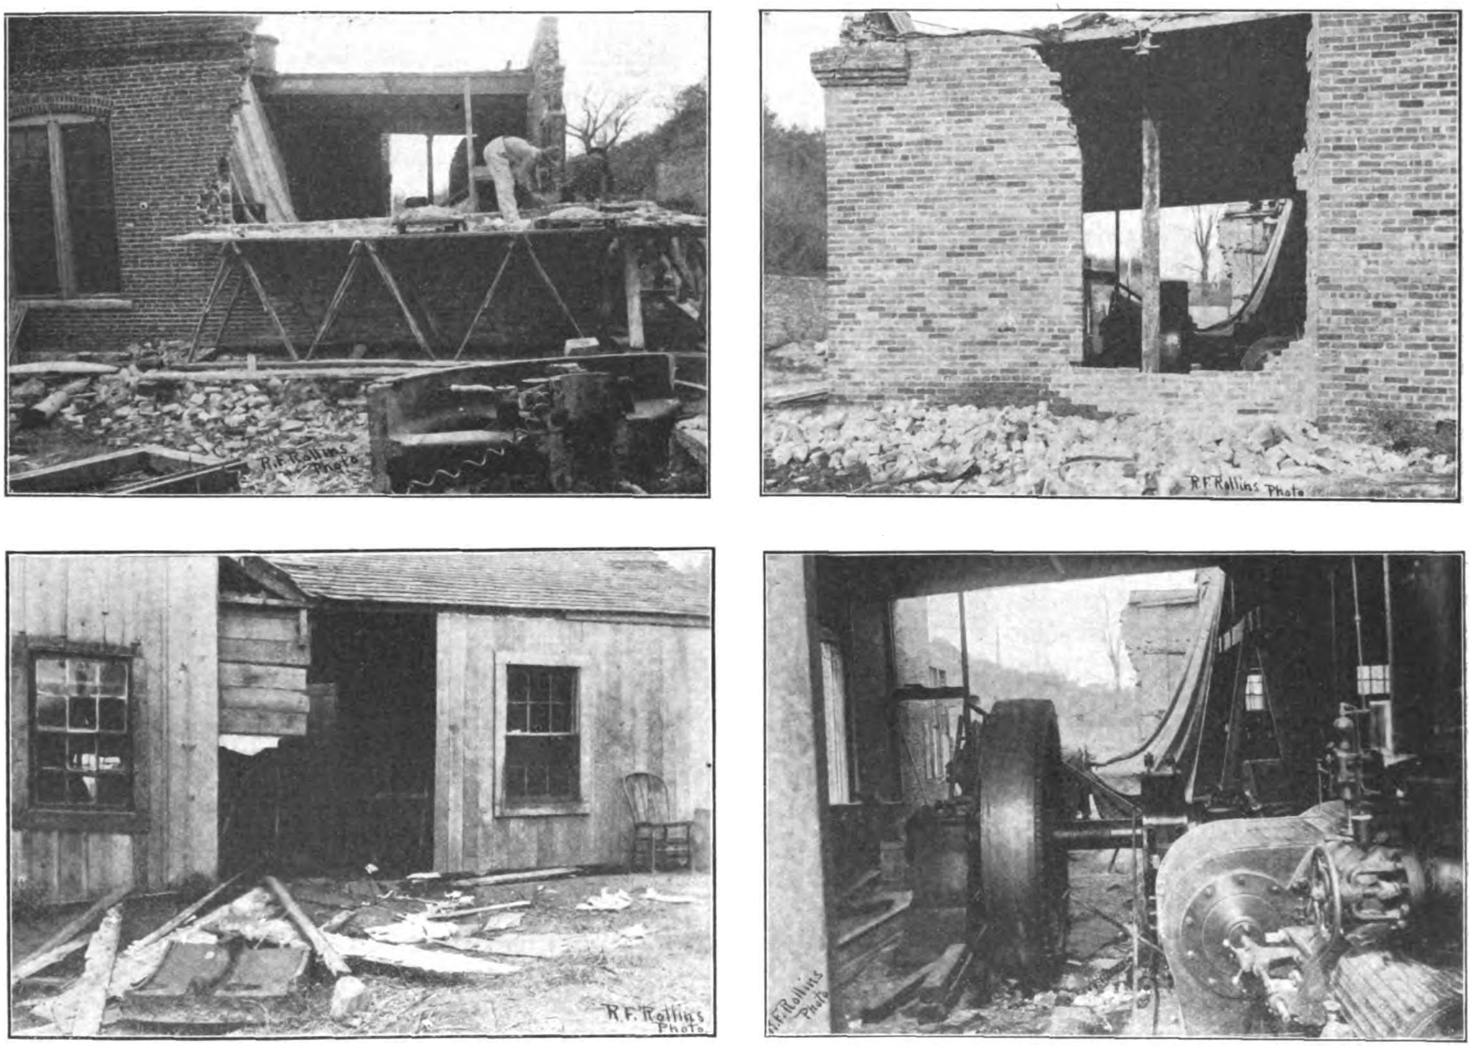
It was while experimenting with electric welding that he invented the so-called repulsion motor, which only within the last few years has been commercially appreciated and now promises to be a formidable alternating-current competitor to the direct-current motor for railway work.

Doctor Rice's paper was discussed by W. S. Andrews, who gave some very interesting information about the early developments in the Edison Company, and by Doctor Steinmetz, who told about the developments in the Eichmeyer Company and the Thomson-Houston Company at Lynn, Mass.

An Electric-Plant Flywheel Accident.

Several weeks ago the big flywheel at the plant of the Keokuk Electric Railway and Power Company, Keokuk, Iowa, burst asunder, partially destroying the building and working a great deal of other destruction. The accident effected the complete isolation of the city as far as the electric lighting was concerned, and was responsible for one sad result, the death of the night engineer. The illustrations herewith are published because of their interest as showing the extent of the damage caused by an accident of this nature. Masses of iron, some of them weighing 1,200 pounds, were carried a distance of 400 feet, and great holes were torn in the north and south walls of the power plant. Inside the station a considerable confusion of machinery resulted.

In the group picture herewith, the one in the upper left-hand corner shows the north end of the power house, with a part of the broken wheel lying in the foreground. The picture alongside shows the south end of the power house. The others show some of the contributory damage.



VIEWS SHOWING THE DAMAGE CAUSED BY THE BURSTING OF A RUNAWAY FLYWHEEL.

THE CONSTRUCTION AND MEASUREMENT OF HIGH RESISTANCE.[1]

By Howard L. Bronson.

The study of the passage of electricity through gases and its application to the measurement of the phenomena of radioactivity has required us to extend our field of accurate electrical measurements. During the past ten years we have become very familiar with the fact that X-rays, ultra-violet light and many substances, such as uranium, radium and thorium ionize the gas in their immediate vicinity —that is, the gas becomes electrically conducting. If the gas between two parallel plates is subjected to a constant source of ionization and one plate is connected to the positive pole of a battery, the other pole of which is to earth and the other plate is connected to an electrometer, then the electrometer will receive a positive charge, showing that an electric current is passing between the two plates. The magnitude of these ionization currents varies from 1-1,000,000,000,000,000 ampere up to currents which can be measured with a sensitive galvanometer. The accurate measurement of the smallest of these currents is by no means an easy task, but the problem is much complicated by the fact that in a large part of radio-active measurements the active matter, and, therefore, the current, is not constant, but continually changes, and sometimes very rapidly. For example, the emanation from thorium decays to half value in little less than one minute. Thus, if we have in a testing vessel a current of 1-100,000,000 ampere, due entirely to thorium emanation and suddenly cut off the emanation, the current will fall to 1-1,000 of its value in ten minutes.

The problem, as presented, is to get an instantaneaus measurement of very small currents. The apparatus must, at the same time, be capable of a considerable range of measurement without serious readjustment. The purpose of this paper is to describe a method which theoretically fulfills these requirements, and which, for many kinds of radio-active measurements, the writer has found to give better results practically than the methods in more common use. It will be seen that this method depends entirely on our ability to make and measure resistances which are sufficiently large and at the same time constant.

As far as the writer is aware, all the older methods for the measurement of these very small currents involve the direct measurement of the change of potential of some system of known capacity. The electroscope is probably the most sensitive instrument for this purpose, as it can be made with a capacity as small as one electrostatic unit, and a change of potential of five volts per hour can be measured. The electrometer, while not quite so sensitive, can measure currents over a much wider range by the introduction of external capacity into the system. A subdivided condenser is very convenient for this purpose.

The use of either of these instruments for the accurate measurement of currents involves many difficulties. The chief difficulty in their use for certain radio-active measurements is that a single observation requires considerable time, during which the current may have changed very greatly. Among the other difficulties may be mentioned:

(1) Changes in the sensitiveness of the instruments.

(2) Lag of the electrometer or gold leaf behind the changing potential, unless its rate of change is very slow.

(3) The accurate measurement of small capacities which have to be redetermined every time a new testing vessel is used.

(4) The long time necessary for the measurement of the natural leak.

In fact, we can say that this method is practically impossible for rapidly changing currents and that it is in all cases inconveniently slow.

The principle of the "constant deflection method," which is described below, is very simple and was first suggested by Rutherford. If one pair of quadrants of an electrometer is connected to earth, Fig. 1, and the other pair is not only connected to the testing vessel, but also to earth, through a very high resistance, it is easily seen that any current in the testing vessel will charge the quadrants until the discharge current through the high resistance is equal to the current in the testing vessel. (This latter current is not diminished by the rise of potential of the quadrants, because the voltage on the testing vessel is always high enough to produce practical saturation.) In this case the current is proportional to the potential on the quadrants—that is, to the deflection of the needle. If the sensitiveness of the electrometer and the actual value of the high resistances are known, then we have at once an absolute measure of the ionization current in the testing vessel. Further, by placing some form of potentiometer between the standard high resistance and the earth, the range over which we can measure currents can be made very large.

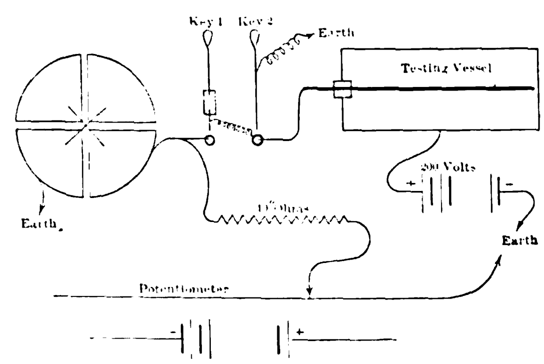


FIG. 1.—MEASUREMENT OF HIGH RESISTANCES.

The advantages of this method are obvious; deflections are independent of the capacity, and testing vessels may, therefore, be interchanged without error, measurements can be made over a wide range without difficulty, and observations can be taken instantaneously and in as rapid succession as desirable.

This method has also several practical advantages. In the rate methods, if the current due to the natural ionization and the conduction across the insulators is small, then it takes a long time to measure it; if it is large, then it may become a considerable fraction of the current to be measured and reduces the accuracy of the measurement. In the constant deflection method, small currents are as quickly measured as large ones, and a considerable amount of insulation leakage introduces no considerable error in the results. When desirable this can be practically eliminated by keeping the electrometer quadrants at zero by means of a potentiometer. By referring to Fig. 1 it will be seen that there are two keys between the testing ves-

[1] A condensation, in part, of a paper on "The Construction and Accurate Measurement of Resistances of the Order of One Hundred Thousand Megohms," presented before the meeting of the American Electrochemical Society at Albany, N. Y., April 30, 1908, by the author, a member of the faculty of McGill University, Montreal.

sel and the electrometer. When both keys are closed the testing vessel and the electrometer quadrants are connected to earth: when key 2 is open the earth connection is broken and the testing vessel is connected to the electrometer; when key 1 is open the electrometer is disconnected from the testing vessel, but remains connected to earth through the high-resistance standard. The reading obtained in this way is the true zero and eliminates certain contact potential differences which have always been found to exist in all very high-resistance standards. This zero can be checked at any time during the course of an experiment. Before any active material is placed in the testing vessel the natural leak is obtained by taking a reading with key 2 open and substracting from this the true zero. This reading is just as quickly taken as any other, and it is evident that its magnitude practically does not affect the accuracy of the measurement to be made with this vessel. It can thus be seen that the method is simpler, more accurate and better suited for nearly all kinds of ionization measurements than the older methods.

The problem then resolves itself into finding out how to make and preserve permanent high resistances of the order of 100,000,000,000 ohms. The great difficulty in doing this is probably the reason that this method has not come into more general use. Very early in the study of this subject it was found possible to get such resistances as large as the above by means of fine carbon lines on ebonite or ground glass, or by means of amyl alcohol or zylol in long capillary tubes. Measurements of ionization currents with these resistances as standards compared favorably with those obtained by the rate methods. There was always, however, considerable variation and uncertainty in all these resistances. The carbon line seemed to have practically its entire resistance at one point and to be merely a

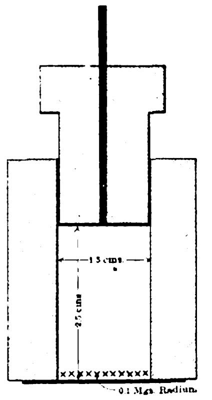

FIG. 2.—STANDARD TESTING VESSEL FOR MEASURING HIGH RESISTANCE.

case of bad contact, which was bound to be very uncertain and subject to all kinds of external conditions. The liquid resistances have very large temperature coefficients and seemed to be subject to a variable polarization. In both classes of resistances there was necessarily present a considerable amount of insulating or dielectric material. The absorption due to this is a function both of the time and temperature. Its effect is to make the apparent resistance less for a time. It may continue for some hours, and is necessarily a very uncertain factor.

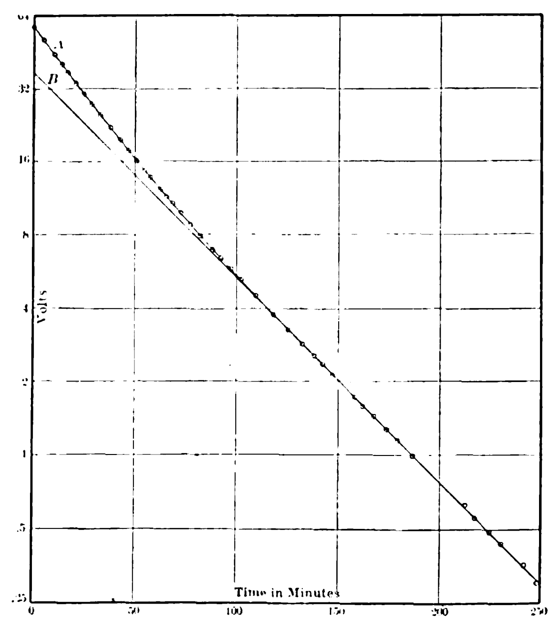

FIG. 3.—MEASUREMENT OF HIGH RESISTANCE.

All of these high resistances proved so satisfactory that Professor Rutherford suggested the possibility of using an ionized gas for this purpose. He had previously shown that the ionization current, through a gas subject to a constant source of ionization, was approximately proportional to the potential difference between the plates when this potential was small. The writer has used this principle successfully for the past three years and is satisfied that it gives as accurate results as any of the rate methods. It is also much less troublesome when it is once arranged and is adapted to measurements for which the other methods are unsuited.

The standard testing vessel, as it is called, has gone through quite an evolution during the past three years. The one at present in use is shown in Fig. 2. The shaded portion is ebonite, the electrodes are of aluminum, and the active material consists of about a tenth of a milligram of radium bromide. In general, the relation between the ionization current in such a vessel and the potential difference between the plates is not linear, but depends upon the nature of the active material used, the kind and amount of insulation and the distance between the plates. However, it is generally possible so to adjust the distance between the plates that a linear relation will exist for a considerable range of potential. Nevertheless, it is necessary to get a calibration curve for every such vessel. This can only be done by some form of the rate method which must ultimately be the basis of all such measurements. However, in the case of a calibration curve the rate method is used under the most advantageous conditions.

Even under these favorable conditions there are many difficulties which are not easily overcome. This is not surprising when it is remembered that the standard testing vessel has a resistance from ten to 100 times as great as the values usually given for the resistance of condensers. In calibrating the standard the condenser is put in place of the testing vessel of Fig. 1 and the system is charged through the standard vessel.

In order to eliminate as far as possible any leakage from the electrometer and condenser the average potential during the time of charging is kept above zero and the total change of potential of the system is never more than 0.2 volt. The error due to absorption by the ebonite of the standard is not very large and can be largely eliminated by applying the potential to the standard a few minutes before taking a measurement. In order to calibrate the standard over a considerable range of voltage, for example, from 100 to 0.1 volt, and at the same time not have too great a change in the rate of movement of the electrometer needle. It is necessary to change the capacity of the system. The accurate comparison of these capacities offers the greatest difficulty to the calibration. The writer used a subdivided mica condenser, the sections having capacities from 0.5 to 0.001 microfarad. Several methods used in calibrating this condenser gave very concordant results for the larger sections, but gave values for the smaller sections which differed in some cases by more than ten per cent from one another. There is the added difficulty in the use of these small capacities that the potential on the standard is also small. Thus, with one volt on the standard a change of 0.2 volt in the potential of the quadrants will change the potential on the standard by twenty per cent.

If we have some radio-active material whose rate of decay has been accurately determined, we can use this rate of decay as a means of calibration. The active deposit from actinum is probably the best substance for this purpose, as its rate of decay has been carefully determined by a number of observers and their results agree very well. The following are some of the best values of the time taken for it to decay to half-value:

Godlewski	36 minutes
Meyer and Schweidler	35.8 minutes
Hahn and Lochur	36.4 minutes
Debeirne	36 minutes

If we take 36 minutes as the mean value it cannot be far from the truth.

In Fig. 3, curve *A* represents the logarithmic decay curve of the active deposit of actinum, as measured by one of the standard vessels. The ordinates represent time in minutes and the abscisse the lag of the voltages on the standard. The straight line *B* represents the relative value of the ionization current at the different times, on the assumption that the active matter decayed to half-value in thirty minutes. If the current through the standard vessel were proportional to the potential difference between its plates, then curve *A* would coincide with *B*. It is evident, from the figure, that the potential increases more rapidly than the current; that is, the apparent resistance of the standard begins to increase when its voltage rises above five volts. The ratio of the abscissæ of curves *A* and *B* at any time is a measure of the resistance of the standard vessel for that voltage. If we thus compare the resistance at twenty, forty and sixty volts, we find that their ratio to be 1 : 1.16 : 1.28. In order to verify these values the actual current through the standard for the voltages was measured by the condenser and rate method. The actual resistances were found to be 0.971×10^{11}, 1.14×10 and 1.25×10^{11}. The ratio of these resistances is 1 :1.17 : 1.28. We thus see that the two methods agree when fairly large voltages and capacities can be used. For the smaller currents the use of a decaying radio-active substance is much the best method.

The results given in this paper would suggest the possibility of making of standard vessels similar to the one here described, and preserving them as permanent high-resistance standards. They would have a much higher resistance than any standards with which the writer is acquainted and ought to remain constant over a long period. They would be found very useful for insulation testing or any very high-resistance measurements.

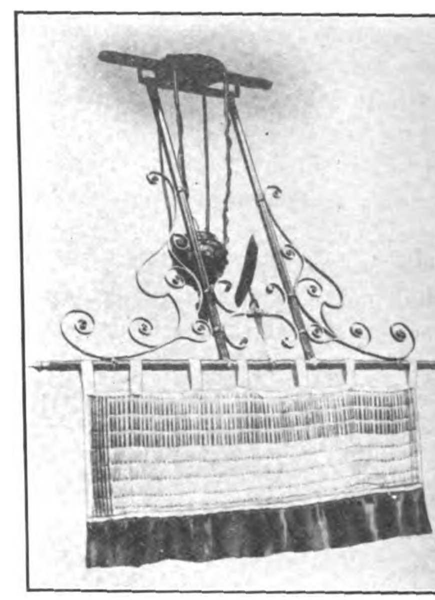
Since writing the above a paper by G. W. Stewart on "A Satisfactory Form of High Resistance" appeared in the April number of the Physical Review. The resistances with which he experimented were not over three megohms, and the results which he obtained with these, such as constancy for all voltages and permanency, would not necessarily apply to resistances 100 times as large, even if similarly constructed. The writer's experience has been that all the difficulties increase very rapidly as the resistances are made larger.

A Motor-Driven Punkah.

The punkah wallah is known to every traveler in the East, and has frequently been described in the literature concerning the eastern peoples. The punkah is considered indispensable in the torrid climate, both as a means of securing a draft of air and in keeping insects from disturbing the sleeper. The native servant continually jerks the rope connected with a swinging curtain which hangs from the ceiling. Frequently the native dozes, and the sleeper is then disturbed.

An electrically-driven punkah has been invented, and although this is not the first of its kind, it is said to give satisfaction because it substitutes for the peculiar jerk which is given by the native, and in which the previously-devised mechanically-driven punkahs were lacking, a similar mechanical movement. The satisfactory service which the hand-worked punkah gives is due to a turn of the fan that the native effects by jerking the rope at each turn. In order to obtain a flick of the curtain similar to that given to the hand-worked fans, the inventors of the new electrically-driven punkah have devised an ingenious piece of mechanism.

A horizontal spindle is made to revolve by an electric motor, and against this spindle there is pressed by means of a spring, a leather-covered, lath-shaped piece attached to the fan. The motion of the spindle makes the attachment move over as far as the length of its surface, and the impetus carries the attachment and the punkah a considerable distance from the spindle. As soon as the lath-shaped attachment comes back to the revolving spindle in the return swing, an extra impetus is suddenly imparted to the swing of the punkah, which gives the requisite flick.



ELECTRIC PUNKAH.

Long-Distance Submarine Telephony.

According to an English newspaper, telephone communication has been opened up between Genoa, Italy, and Buenos Ayres in South America over the submarine cable system connecting them. The preliminary tests are said to be a successful demonstration of an invention by Captain Anzalone, an officer of the Italian army. After working for some time in France, he made a number of trials of submarine telephony across the Straits of Messina. The secret of his method is not disclosed, but its success is strongly asserted.

Electrical Smelting of Iron.

To the Editor of the Electrical Review:

I note your remarks in editorial of August 15, re my estimate of cost of production of pig iron at the plant of the Noble Electric Steel Company at Heroult, Cal. In order to show how conservative the estimate is I will explain some of the details.

The figure of $1.75 per ton for iron ore is quite reasonable, for the mine is only two miles back of the smelter and is open quarry. The limestone is also open cut and $1 is ample for its cost. The andesite is even closer.

The figure of $10 per ton for charcoal is very high, for we have a plant installed to conserve the by-products, and the manager of the by-products says that he can deliver the charcoal to the smelter at no cost to the smelter.

The figure of 0.31 kilowatt-year per ton of iron produced was based on the run of a small furnace in which the losses were inordinately high and which only ran for ten days. The energy for heating up the furnace is quite an appreciable percentage of the total current used, when such a short period is taken account of. A furnace of about two tons capacity per diem has been run for thirty-five days and shows that the energy can be kept to 0.31 kilowatt-year without any trouble if the furnace is kept running at all continuously.

The labor cost figures high, for operations are done by hand in a small furnace which would be done mechanically in a large furnace. Two furnaces of this size could just as well be run with the same amount of labor.

Eliminating the charcoal would make a price of $9.65, and adding the $2.50 per ton for incidentals would give $12.15. Figuring in two furnaces would reduce the figure to $11.20. Thus it seems to me that my estimate of $16.14 per ton is well within reason. That this cost of production is commercial is due to the fact that pig iron is worth $28 per ton on the Pacific Coast. With a freight rate of $2 per ton to San Francisco, it seems as if $25 per ton f. o. b. Heroult is practicable.

As to size of units it is my opinion that as soon as a fifteen-ton furnace using 1,500 kilowatts can be operated commercially that larger furnaces using larger blocks of power will be put into operation. With the advent of the larger units will come mechanical power feeding and other labor-saving devices, which will tend to keep the cost of production to a point at which the electrical furnace can be entirely successful in the localities adapted to its use.

C. F. Elwell,
Electrical Engineer for Noble Electric Steel Company.

San Francisco, Cal., October 24, 1908.

The Windmill as a Prime Mover.

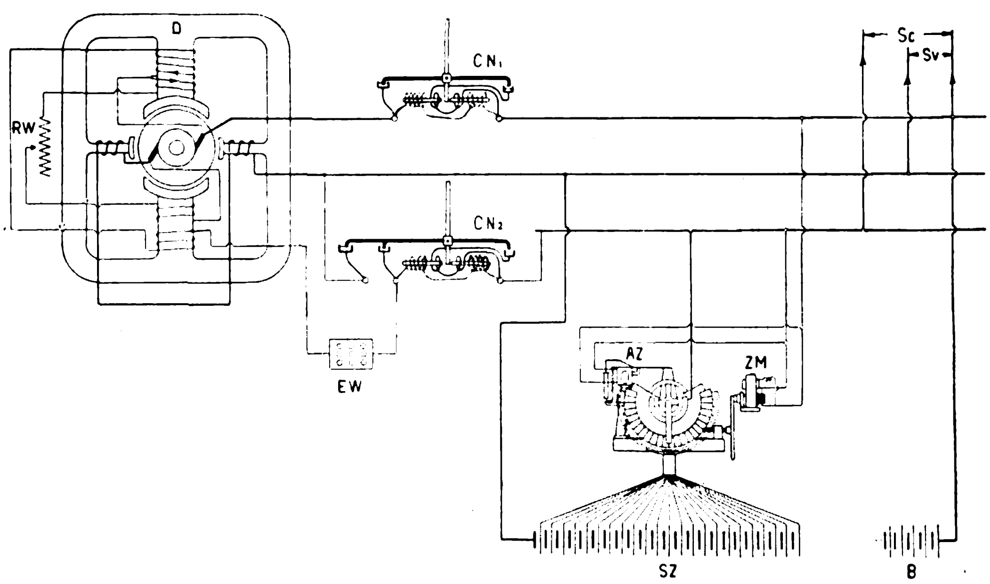
The advantage of utilizing the force of the wind lies in the fact, that this source of power does not cost anything and the upkeep is very low. As the output of a windmill plant is naturally small, the electric current can be used for lighting, agricultural purposes, or other small industries. For such consumption, it would probably not pay to install a private or isolated plant run by some other source of energy, and right here it must be borne in mind that the smaller the plant, the greater the comparative cost of attendance, and because the windmill runs intermittently, the generator outfit must operate automatically.

The vanes of the sweeps or wheels must be so arranged, that they can accommodate themselves to the pressure of the wind, and the other everyday features found in air motors are the same as used for operating pumps, churns, etc.

The ordinary equipment would be a direct-current dynamo, a storage battery and two automatic regulators. By means of the latter, the storage battery is maintained at its normal voltage and capacity. The excitation of the generator is controlled automatically. During operation, the storage battery is fed by the generator, except when there is a demand for power, and it is then used to assist the generator.

After the storage battery becomes fully charged it is automatically cut out, until needed, when it is thrown on the line. When there is no load and the battery is out, the generator is free to run idle.

In certain sections of the country, the period of calm covers about ten per cent of the year, and in order to have a reserve supply, a benzine motor may be advantageously installed as an emergency power source. Several such installations have been successful in operation for some time. The accompanying illustration shows the wiring diagram of units from three to thirty horsepower capacity, with automatic regulating devices as installed by the Oerlikon Company of Switzerland. The references are as follows: D, dynamo; R W, field rheostat; C N_1 and C N_2, automatic switches, combined system of Thury and La Cour; E W, rheostat; A Z, automatic cell switch; Z M, motor for cell switch; S Z, end cells; B, storage battery; Sv, variable pressure mains; Sc, constant pressure mains.



THE WINDMILL AS A PRIME MOVER—DIAGRAM OF CIRCUIT CONNECTIONS.

The American Trade Press Association.

At the annual meeting of the American Trade Press Association, held in New York city on November 6, the following officers were elected for the ensuing year: President, Franklin Webster, *Insurance Press;* first vice-president, W. H. Boardman, *Railroad Gazette;* second vice-president, John C. Oswald, *American Printer;* third vice-president, H. M. Swetland, *The Automobile;* secretary-treasurer, L. J. Montgomery; all of New York, N. Y. E. C. Brown, *Progressive Age,* New York, N. Y., was elected a director to serve four years.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

AIRSHIPS AND WIRELESS TELEGRAPHY.

Wireless telegraphy tests have been made between the balloon Condor, which ascended in the neighborhood of Brussels, and a station erected in the tower of the Brussels Palace of Justice. Morse signals sent from the Eiffel Tower, in Paris, were also clearly received by the balloon. That the German Airship Battalion has made extensive experiments with wireless telegraphy has been already recorded. The apparatus used were furnished by the Telefunken Gesellschaft. Several years ago Professor Hergesell of Strassburg, made some telemechanical experiments with unmanned registering balloons. Attached to the same were small receiving stations which, upon the arrival of the electric waves, actuated a valve and caused the balloons to fall. Each balloon was attuned to a certain wave-length. Thus, it was possible for the vessel, from which the balloons were sent up, to bring down any one of them at will, while the others remained in the air. The experiment was successful up to a distance of ten nautical miles, and wireless communication between flying balloons and land stations was at that time already considered possible. But at the airship trials this year it was feared that, if wireless apparatus were taken on board, sparks might be generated, which would cause serious consequences by exploding the gas. However, recently it seems to have become possible to remove this danger and to guarantee a safe wireless communication between balloons.—*Translated and abstracted from Elektrotechnische Zeitschrift (Berlin), October 22.*

SOME NOTES ON TWENTY-FIVE-VOLT WIRING.

While the twenty-five or fifty-volt metal-filament lamp has not yet come into extensive use, it has a decided advantage over the more common 110-volt tungsten and tantalum lamps on account of its thicker and shorter and therefore more rugged filament for the same candlepower. This feature, combined with the fact that the low-voltage lamps can be run at a higher efficiency, will repay the cost of a small loss in the transformer. In rewiring a building or in designing a new installation four kinds of transformers may be used. To compare their relative advantages it is desirable to assume a maximum load of 1,000 watts on the secondary, i. e., twenty-five volts and forty amperes, the primary voltage being 200. The first type considered is a single-coil transformer with seven uniformly-spaced taps, which, in conjunction with the outside wires, lead to eight equally-loaded, twenty-five-volt branch circuits. The no-load and full-load losses would each be about two per cent and the maximum transformer loss occurs when only half the circuits are loaded, the loss being then five and three-fourths per cent. Voltage regulation is perfect at any balanced load. At half load the voltage drop is greatest (about one per cent). Although each circuit is twenty-five volts, there may be 200 volts between different circuit wires, which must be provided for in the layout of the panel-boards and distributing system. On account of the difficulty of dividing the circuits evenly, the balancer transformer just described is not so convenient as the auto-transformer, which has only one twenty-five-volt circuit. In this case the losses would range from two to nearly five per cent from no load to full load and the greatest voltage variation would be three and three-fourths per cent. If wired up without special care, there may be 200 volts between the lamp-circuit wires and ground. Where a simpler and cheaper wiring system is desired, which will at the same time be entirely independent of the primary circuit, a regular double-coil transformer with twenty-five-volt secondary is necessary. These advantages are so valuable that they may outweigh the increased cost and losses of the transformer as well as its poorer regulation. An additional and very marked advantage of this transformer is that it permits the use of concentric wiring with grounded outside metallic return. This wiring should be the cheapest form of wiring, it is said, because it saves half the insulated wire, half the fuses, and secures absolute immunity from shock or leakage currents. By using a three-wire secondary the cost and losses of the transformer are diminished, each circuit consisting of a three-conductor tube with two insulated wires in a metallic tube acting as the neutral or grounded return. The lights are connected between the tube and one of the insulated wires. This system has the advantages of fifty-volt distribution with the desirable feature that no part of the secondary circuits is more than twenty-five volts above ground. Either of these concentric wires if made of flexible tubing is regarded as the final solution of the cheap-wiring problem. They are safe, easily fixed, inconspicuous, not easily damaged, and at the same time the cheapest to install. Some slight modifications of existing wiring rules may be necessary to carry this system out. For private lighting plants where storage batteries are used, the twenty-five-volt system enables the number of batteries to be reduced, thus reducing both initial and maintenance costs. Wiring lamps in series, to enable twenty-five-volt units to be used, is increasing, especially for wiring up chandeliers and lamp clusters, which can be readily changed from parallel to series-wiring. By using specially shunted lamps for such fixtures, the breakage of one lamp does not interfere with the remainder of the series.—*Abstracted from Electrical Engineering (London), October 29.*

UTILIZATION OF COKE DUST FOR THE PRODUCTION OF POWER GAS.

An advance is to be recorded in the utilization of cheap refuse fuel. The production of coke in smelters and gas works is attended by a loss of three to ten per cent in the form of dust, which in Germany amounts to about 700,000 tons a year. The smoke chamber refuse of locomotives, which amounts to about 200,000 tons a year in Germany, also belongs in this class of refuse fuel. The price obtained for the same, if at all salable, is about eighteen marks for ten tons. Finally there is a large quantity of anthracite dust produced at the mines. All this fuel material which so far could be burned only with difficulty and incompletely on account of the formation of slag, can now be utilized in the new Nuremberg fine-coal generator, which has been put on the market by the Maschinen Fabrik Augsburg-Nuernberg after several years of experimentation, with perfect ease, economy and reliability of operation. A seventy-two-hour test was made with one of these generators and a 200-horsepower gas engine under widely varying loads. The average fuel consumption was only 0.63 kilogramme per horsepower-hour under a small load, including all losses, firing-up and cleaning. This corresponds to an hourly fuel cost of only 0.1 to 0.4 pfennig (one-quarter to one cent) per horsepower. A new source of power of extraordinary economy has thus been created by these generators, primarily for such industries as coal and anthracite mines, gas works and railway power stations, which may themselves use this low-priced fuel. The municipal gas works of Munich and Berlin have already been induced by these economic advantages to furnish their new power stations with coke-dust power equipments of 800 to 1,000 horsepower each, which will be installed by the above firm.—*Translated and abstracted from the Journal fuer Gasbeleuchtung (Munich), October 17.*

THE FORMATION OF NITRIC OXIDE IN THE HIGH-TENSION ARC.

Professors F. Haber and A. Koenig here give some results of their investigations of this subject. In a previous article they endeavored to demonstrate that while the formation of nitric oxide in high-tension arcs can be conducted so that it is a purely thermal phenomenon, this procedure is not at all commendable theoretically. Their method of operation was, therefore, in a direction opposite to that followed formerly. In old experiments an effort was made to heat the gaseous conducting space to the highest possible temperature and then to cool it as rapidly as possible, while they attempted to cool the gaseous conducting space during the passage of the current, so that an extremely high temperature did not exist at all. At an extremely high temperature the primary electrical effects are masked by the accompanying thermal manifestations. With the method of operation employed these manifestations did not take place. The experiments were carried out with nitrogen-oxygen mixtures, but although relatively good results were obtained, they were too far removed from the quantitative transformation of nitrogen and oxygen into nitric oxide. The supposition was expressed, that it might be a question here of an electric equilibrium, which supposition the authors have confirmed by further experiments. Identical results are obtained when starting with nitric oxide as when starting with nitrogen-oxygen mixtures. The results are dependent upon the conditions of the electrical experiment. Thus the same stationary condition is reached from both directions. This condition has been named the electric equilibrium, as distinguished from the thermal equilibrium. While the position of the thermal equilibrium of the three gases, nitrogen, oxygen and nitric oxide, is distinguished only by effects of temperature and mass, the authors define the electric equilibrium as one for which, in stationary condition, a certain expenditure of electrical energy in a unit of time is also required, the amount depending on the extent of the deviation from the thermal condition of equilibrium. If we indicate by K_t the constant of equilibrium, in the ordinary sense, thus

$$K_t = \frac{(NO)}{(N_2)^{1/2}\,(O_2)^{1/2}}$$

and designate by $K_e = \dfrac{(NO')}{(N_2')^{1/2}\,(O_2')^{1/2}}$ the relation of combination upon the expenditure of a certain amount of electrical energy, dependent on the conditions of the experiment, then under the assumption of equal temperature in both cases the performance will be $R\,T\ln\dfrac{K_e}{K_t}$, a measure of the displacement of the electrical equilibrium with reference to the nitric oxide molecule. Evidently K_e may be smaller as well as larger than K_t, in the proportion as the thrust of the ions benefits the formation or decomposition of the nitric oxide. If the latter should be the case, one would have to endeavor to cover the electrical by the thermal effects. But if the opposite is the case—and this is the view of Professors Haber and Koenig—then the thermal effects must be repressed in order to allow the electrical effects to predominate. The relation of the thermal to the electrical effects depends on the rapidity with which the (formation and) decomposition of nitric oxide at the temperature of the experiment takes place in a non-electrical way. Two extreme cases offer themselves for consideration. When dealing with a temperature region in which the rapidity of (formation and) decomposition of the nitric oxide is practically zero, then the position of the electric equilibrium indicated by the constant K_e will entirely depend on the measure with which the electron thrust affects the formation and decomposition of nitric oxide. If, on the other hand, we are in a temperature region, in which the nitric oxide decomposes with extreme rapidity, then there cannot be any appreciable difference between the electrical and thermal equilibrium, that is, between the constants K_e and K_t, because every electrically produced increase of nitric oxide will disappear instantly again. It follows from this, that the thermal can be repressed in favor of the electrical effects only when the operation is carried on in temperature regions, in which the rapidity of decomposition of nitric oxide is still comparatively small. The authors have proved by experiments, that under the conditions of operation employed by them the nitric oxide is indeed decomposed with measurable slowness in the conducting path; this fact forming an essential basis for their former result, which was arrived at by calculation, that in their cooled high-tension arc the temperature of 3,000 degrees Centigrade is not reached. The farther we descend with the temperature, the more we are insured against the thermal decomposition of nitric oxide. But it seems, according to all that may be learned from technical literature in this respect, that the expenditure of electrical work for the production of gas ionization increases considerably by thrust, if we descend with the temperature below white heat. There must thus be a most favorable temperature region, which is defined above by the rapidity of decomposition of the nitric oxide, and below by the high ionizing effects. The authors then describe their experiments undertaken for the purpose of determining this "most favorable region," giving tables of the results obtained, and conclude: "The most important result of this work is, that the unusually high proportion of nearly ten per cent of nitric oxide was obtained, when air was used, and fourteen and one-half per cent from mixtures of nitrogen and oxygen in equal parts, and this at temperatures in the discharge gap at most in the hundreds, but not thousands of degrees above the fusion point of platinum—that is, in a temperature region in which the decomposition of nitric acid was still comparatively slow. The electrical character of the nitric oxide equilibrium observed by us in the high-tension arc thus appears to be demonstrated."—*Translated and abstracted from Zeitschrift fuer Elektrochemie (Halle), October 9.*

INDUSTRIAL SECTION

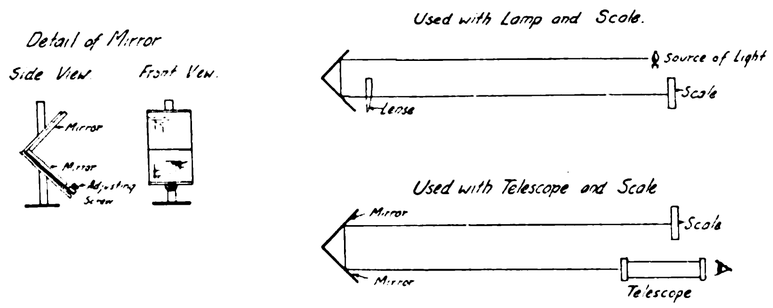
ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

Anti-Vibration Device for D'Arsonval Galvanometers.

In many places, such as factories, shops and laboratories, where galvanometers are used, the shaking is so great that it produces vibrations of the coil that make an accurate scale reading impossible. These vibrations are of two classes; those about the vertical axis of the coil, and those about the horizontal axis. The first are quickly damped by the current itself, but the latter must be stopped mechanically. Up to this time practically the only satisfactory remedy for this trouble has been in the expensive Julius suspension, which is hung from the ceiling, and supports the whole galvanometer.

In contrast to this large and cumbersome affair is the small attachment recently brought out by the Leeds & Northrup Company, of Philadelphia. This device consists of a small, light framework weighing about 0.4 gramme, which is fixed rigidly to the moving system of the galvanometer. By means of this, the horizontal vibrations are quickly damped.

As an adjunct to this, to be used where the vibrations are unusually severe, there has been devised a new form of reflecting mirror, as illustrated herewith. This absolutely eliminates to the eye, any oscillations about the horizontal axis that the coil may take on. In fact, the system may be tilted backward and forward, or the arm and scale raised and lowered several inches, without disturbing the scale image in the telescope.



ANTI-VIBRATION DEVICE FOR D'ARSONVAL GALVANOMETERS.

These anti-vibration devices may be attached to any galvanometer with a suspension of four inches or over, and are suitable for use with a telescope or a lamp and scale.

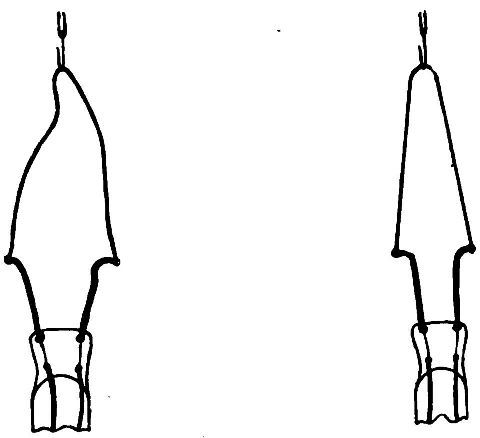
Severe Lightning Test on Tungsten Street Lamps at Hackettstown, N. J.

During a severe lightning storm in Hackettstown last July, the series incandescent line was struck, the discharge passing through thirty-three series tungsten lamps. The filaments were slightly curled as is shown by the illustration, but the lamps did not burn out. On investigation it was found that the film cut-outs in the sockets were punctured, and when new films were installed, the lamps lighted up again, the tungsten lamps withstanding the shock without breaking. It is doubtful whether a carbon-filament lamp would have withstood this severe shock. This same stroke of lightning burned out three transformers, then jumped to a private house, ripping off a door sill, and passed into the ground through a steam radiator, knocking unconscious a woman who was standing nearby.

The following extract of a letter from Mr. P. Louis Smith, superintendent of the Hackettstown Electric Light Company, regarding the occurrence, is of interest:

"You will note the twisting of the filament of the first sample I sent you, also the second sample which we found a few days later, the filament still intact, only loose from the anchor. This lamp was at the end of a loop about 500 feet long, branching from our main street to a side street. The lightning here was so severe that it struck our lines in four or five places, thus following our wires in several directions at the same moment. The top of one transformer was thrown 200 feet from where it hung on a pole, and the second sample street lamp I sent you was on the next pole to this particular transformer—another severe test.

"We have 123 tungsten lamps on our street circuit, thirty-three were put out temporarily because of the mica disc taking care of the shock. When new discs were installed the lamps burned all right. The lamps have burned to date (August 18) about 150 hours since they were twisted by the lightning, making a total of about 1,400 hours since their installation. We are very pleased with these results.



TUNGSTEN FILAMENTS AFTER LIGHTNING DISCHARGE.

"Last year we had a severe lightning storm here and it burned out fifteen carbon lamps and melted the sockets completely. Thus our change has almost been paid for in obtaining such good results from the new sockets and lamps."

A New Type of Reflector Distribution.

The new "intensive" type Holophane high-efficiency reflector, recently designed for tungsten lamps, introduces an entirely new type of light distribution.

The primary purpose for which this reflector was designed is that of illuminating evenly a large surface by means of distributed units placed in the form of squares. This system is used commonly in department stores, restaurants, hotels and club lobbies, large offices, assembly rooms, halls of moderate dimensions, council chambers, court rooms, etc., where the lights are hung above the plane of illumination.

When distributed units are employed, the lighting problems are all essentially the same, variations being due to architectural restrictions and the quantity of illumination desired. The point always at issue is to secure uniformity of illumination. While this problem was solved more successfully by the original bowl-type Holophane reflectors designed for Gem lamps than by any other equipment in the market, it was felt that an improvement should be made.

In designing the intensive type of reflector, a typical installation was planned,

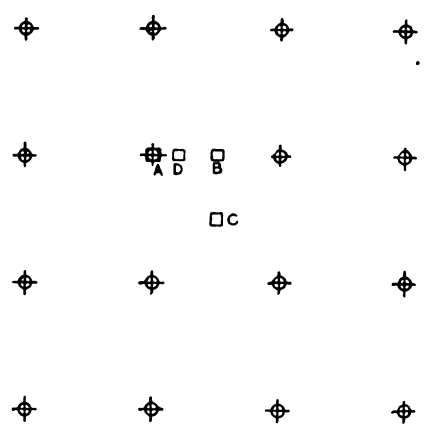


FIG. 1.—TYPICAL PLAN OF DISTRIBUTED UNIT SYSTEM.

as indicated in Fig. 1, in which the circle-cross symbol represents the lights (which may extend indefinitely in any direction), and the square symbols, points which would represent an average of the entire space illuminated.

By patient and exhaustive calculation there was determined a photometric curve which gives the same illumination at all

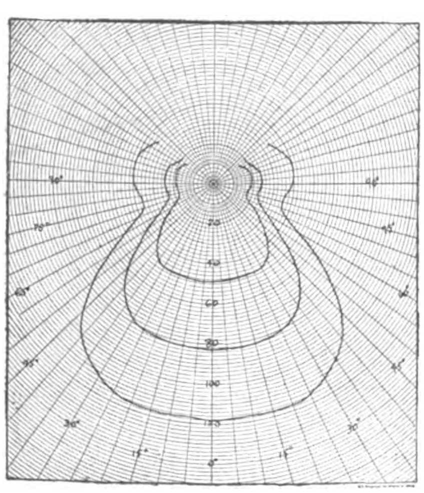

FIG. 2.—CHARACTERISTIC PHOTOMETRIC CURVES OF INTENSIVE REFLECTORS, THE VALUES INDICATED BEING APPROXIMATE ONLY.

these points, taking into consideration all the units in the installation. This curve (Fig. 2) is the basis of the intensive reflector, which not only gives even illumination in such service, but it gives approximately such a result despite reasonable variations in placement; that is to say, where architectural limitations preclude placing the lights at exactly the proper distances apart in proportion to their height from the floor, such moderate variation in placing will not appreciably affect the uniformity of illumination.

The successful use of this reflector does not call for any considerable knowledge of illuminating engineering. The desired light intensity in foot-candles having been determined, one employs the "lumens-per-watt" method of approximating the wattage required in a given room. This simple method was devised by Messrs. Cravath and Lansingh and presented by them before the Illuminating Engineering Society's recent convention at Philadelphia. With the required wattage known, it is only a matter of dividing this amount by the wattage of the tungsten lamps when it is desired to ascertain the number of lamps required in the installation. These lamps, equipped with proper size Holophane intensive reflectors, are installed as nearly as possible in the form of squares, their height above the plane of illumination being four-fifths of their distance apart. The distribution of the intensive Holophane reflector is so carefully calculated that anyone following the above simple rules cannot well avoid securing satisfactory results.

A Compound for Repairing Iron and Steel.

Great expense is incurred in replacing machinery parts, engine cylinders, castings, radiators, boilers, and other iron and steel objects which have become useless because of cracks, spongy spots, sand holes or blow holes, and which could be saved were it possible to repair defects in the metal. Under the name "Leak-No Metallic Compound" the H. W. Johns-Manville Company, New York, has placed on the market a compound resembling powdered iron. When mixed with water, and applied like putty to defects in iron or steel articles, the manufacturers claim that it metallizes and becomes a permanent part of the article to which it is applied. In color it very much resembles iron when hard.

The manufacturers evince their faith in this material by offering to refund the purchase price in case it fails to stop an ordinary leak in anything made of iron or steel against any pressure of oil, steam, gas, air, ammonia or water, and to stand any heat or chemicals that iron will stand, when applied according to directions. This it considers is a liberal offer, and enables anybody to test this material without expense, if it does not make good.

Useful Properties of Logarithmic Paper.

A useful form of co-ordinate paper for plotting curves, in which the variable occurs in some power other than the first, is the so-called logarithmic cross-section paper whose divisions are proportional to the logarithms of the numbers expressing the distances to the origin instead of being proportional to the numbers themselves, as in the case of the ordinary equi-spaced rectangular co-ordinates. The rulings of the logarithmic scale are disposed similarly to the divisions of a slide rule, and, indeed, the ordinary slide-rule operations can be performed by the use of two sheets of logarithmic paper properly placed.

The peculiar and useful feature of paper divided according to the logarithmic scale is the property by which curves of any exponential degree become straight lines when plotted to this scale. Thus, it becomes possible to locate any two points on a curve, and with a straight-edge to draw in the curve at once without determining any intermediate positions. On logarithmic paper the parabola, for instance, becomes a pair of straight lines of definite slope arranged as a V with the vertex at the origin.

Absolute or empirical formulæ involving integral or fractional exponents may be quickly plotted after determining any two points, and from the line representing the curve any certain values may be obtained by reference to the co-ordinates.

A logarithmic paper which has the advantage of a graduation from ten to 10,000 has been placed upon the market by Mr. J. Norman Jensen, a civil engineer, 797 N. Leavitt Street, Chicago. The diagram is ten inches square and comprises, in fact, four complete logarithmic sheets. Among the more common uses to which this paper may be put with advantage, may be enumerated the following calculations: Powers and roots of any and all indices; bending moment, shearing stress or deflection of beams in terms of span or load; moments of inertia and radii of gyration in terms of a linear dimension; circumferences and diameter of circles in terms of their radii or diameter; sizes of tie bars, struts, shafts, etc., in terms of linear dimension or inverse, etc., etc.

The diagram is printed in a neutral tint, permitting of ready photo reproduction and blue printing. The paper is of good quality bond, which may be roughly handled and on which erasers may be used, and is thin enough to admit of blue printing readily.

A New Lamp-Testing Wattmeter.

A practical demonstration of the high efficiency of the new metallic-filament incandescent lamps will often aid in their introduction, particularly with prospective customers to whom seeing is believing. All that is necessary to make such a test is a simple indicator that will show the relative watt consumption of metallic and carbon-filament lamps, and for this pur-

TYPE L, 125-WATT, LAMP-TESTING WATT INDICATOR.

pose the lamp-testing watt indicator, here described, has been designed by the General Electric Company, Schenectady, N. Y. This instrument should prove especially valuable in introducing the new 25-watt tungsten lamp, although this is not essentially the only use to which it can be put, and many other conditions may arise where it will be found of immediate service, and where a larger and less compact apparatus would be at a disadvantage. In addition to its utility, it possesses the merits of accuracy in operation, facility of reading, and attractive appearance.

This watt indicator is constructed on the Thomson inclined-coil principle, and has a scale marked directly in watts, at different voltage values. The moving element is mounted in jeweled bearings. The case consists of a single aluminum-alloy casting, on each side of which is a brass dome. At the top there is an Edison screw plug, and at the bottom a lamp receptacle.

Although the lamp-testing wattmeter is intended for use with Edison sockets and lamps equipped with the Edison base, an adapter can be supplied, permitting its use with either the Thomson-Houston or Westinghouse socket or lamp base.

To use the instrument, the plug is screwed into a lamp socket, and the lamp to be tested is inserted in the receptacle at the bottom of the instrument. The pointer will then indicate the watts consumed by the lamp. The plug end of the instrument is equipped with a spring-contact end, permitting an extra turn so that the scale may always be in full view.

The instrument is provided with a multiple scale, allowing direct readings when used on 100, 105, 110, 115 and 120 volts. For intermediate voltages readings may be interpolated. The capacity of the winding is one and one-half amperes, and the maximum scale marking is 125 watts. The size of the instrument is such that it can be conveniently carried in the pocket.

A Weight Computer for Structural Shapes.

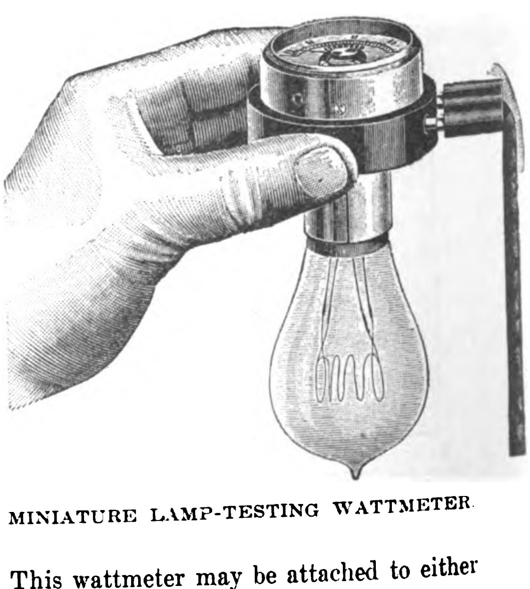
The calculations required to be made by a structural engineer in designing any bridge, roof truss or other steel structure are quite laborious. To make this work more rapid and less irksome, a number of calculating machines have been developed. The simple slide rule is one of the most common. A useful and convenient adaptation of the slide rule for the determination of weights of structural shapes has been brought out by the Edge Computer Sales Agency, St. Paul Building, New York, N. Y. The Edge computer consists of two discs, one rotating above the other. Each disc has its circumference marked off with logarithmic scales representing the dimensions of the various shapes in feet and inches and the resultant weight in pounds. In determining the weight of a plate the upper disc is turned until the thickness of the plate required corresponds with the required width on the lower scale. The weight of any length of that plate is then seen on the lower disc opposite the length. For computing the weights of angle-irons a similar simple operation is necessary. In the same way the weight of any length of a beam, channel iron or other structural shape, whose weight per foot is known, can be readily computed without reference to any tables or books, and with an accuracy much higher than is required for most practical purposes.

Important Order for the Crocker-Wheeler Company.

One of the most important orders recently booked in the electrical field is that for about 2,500 horsepower of induction motors for the Clark Thread Company, in Newark, N. J., which has been secured by the Crocker-Wheeler Company, of Ampere, N. J. The order is of considerable size, but its chief importance is because of the fact that it is the beginning of the electrification of these mills, which are probably the most extensive in the United States. The mill has been driven by several steam engines, and this purchase of induction motors is the first step in electric drive. The order was awarded to the Crocker-Wheeler Company after a thorough investigation extending over a period of ten months, which demonstrated that the Crocker-Wheeler engineers knew how to solve the intricate electrical problems met with in textile work. The motors are wound for 5,500 volts, sixty cycles, three-phase, and will range in capacity from twenty-five to 150 horsepower each.

A Miniature Wattmeter.

The accompanying illustration shows a miniature wattmeter for incandescent-lamp testing which has been placed on the market by the Robert Instrument Company, 56 Shelby street, Detroit, Mich.



MINIATURE LAMP-TESTING WATTMETER.

This wattmeter may be attached to either direct or alternating-current circuits, within the range of the wattage and voltage calibration of the instrument (150 watts at 118 volts). The attaching plug, cord and connector are furnished with each instrument. The maker claims that the meter is particularly adapted for testing the efficiency of tungsten lamps.

A Motor-Operated Time Switch

A non-arcing time switch for closing and opening a circuit at predetermined times has been invented by Bernard Tropp of New York city and patented in this country. It is entirely automatic and requires only rewinding of the clock mechanism controlling it.

This clock controls two contact devices, each operated once every twenty-four hours, for completing a circuit through a small electric motor, which mechanically actuates a switch in the lamp circuit. The motor runs long enough to actuate the lamp switch and then automatically switches itself out of the branch circuit. There are also manually operated switches for cutting out the contact devices at the clock momentarily, and permitting the motor to be set in motion independently of the clock, for turning on or off the lights.

In the accompanying drawings of the device, Fig. 1 is a plan of the device, and Fig. 2 is a side elevation thereof.

The clock (1) has a wheel (2) which makes one rotation in twenty-hour hours. The arbor of this wheel is connected with an aligned metal shaft (4) through a block (5) of insulating material. As the shaft conveniently forms a part of the motor circuit, this block interposes between the shaft and the metal of the clock mechanism, and thus avoids risk of a shock to one winding the clock.

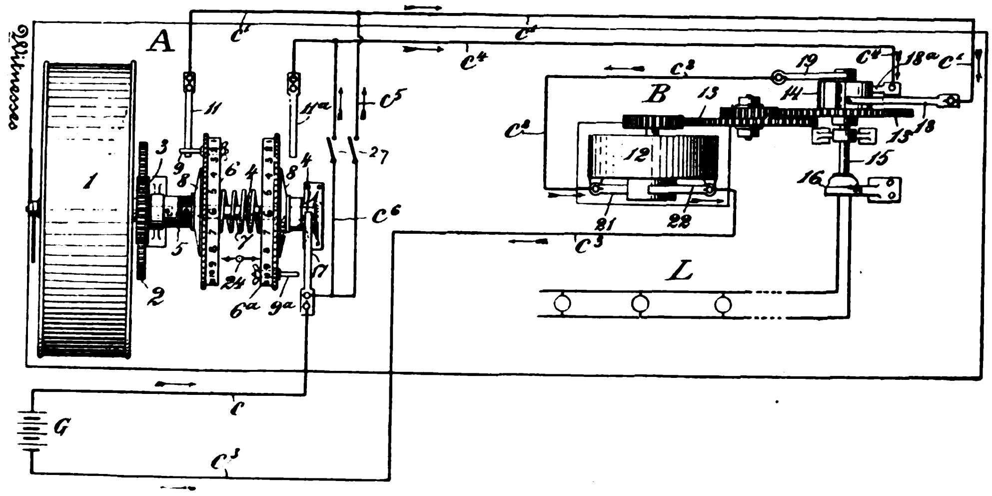


FIG. 1.—DIAGRAM OF CONNECTIONS, TROPP AUTOMATIC TIME SWITCH.

Mounted on the shaft are two like contact wheels (6) and (6^a). These are driven frictionally with the shaft, being pressed outward by a spring (7) against collars (8) on the shaft. These wheels are provided, respectively, each with a contact stud (9) (9^a), and, for purposes of angular adjustment, the studs are mounted in curved slots in the contact wheels. There are two light spring terminals (11) and (11^a) in the paths of the respective studs.

The motor section of the apparatus comprises a small electric motor (12) which drives, through a reducing train of gears, a rotary circuit-breaker (14) on a shaft (15), which forms the operating spindle of a rotating switch (16) in the lamp circuit (L). A high-speed motor is essential to the proper operation of the switch shown, which may be of the well-known kind which operates at each quarter of a rotation of the spindle to alternately close and break the lamp circuit. The shaft carries two oppositely disposed and laterally projecting spring blades of metal which are connected electrically and which, in one position, connect the wire terminals of the lamp circuit electrically. When the shaft is turned a quarter way round, the blades are moved out of contact with the wire terminals, and the lamp circuit thus broken.

The motor circuit may be supplied with electric energy from any source, as a battery (G). The current goes to a brush (17) bearing on the shaft (4), through the shaft to the wheel (6) and stud (9) to the spring terminal (11), and thence to a brush (18), which is in contact with the circuit-breaker (14). From this device the current is taken off by a brush (19) and carried to one of the brushes (21) of the motor, thence through the motor to the other brush thereof, and thence to the other pole of the source (G). As the wheels (6) (6^a) are constantly (though slowly) rotating, when the stud (9) contacts with the spring terminal (11) the circuit will be completed through the motor and the latter, through the gear train, will set the circuit-breaker (14) to rotating. This operates the switch (16) to turn on the current to the light circuit.

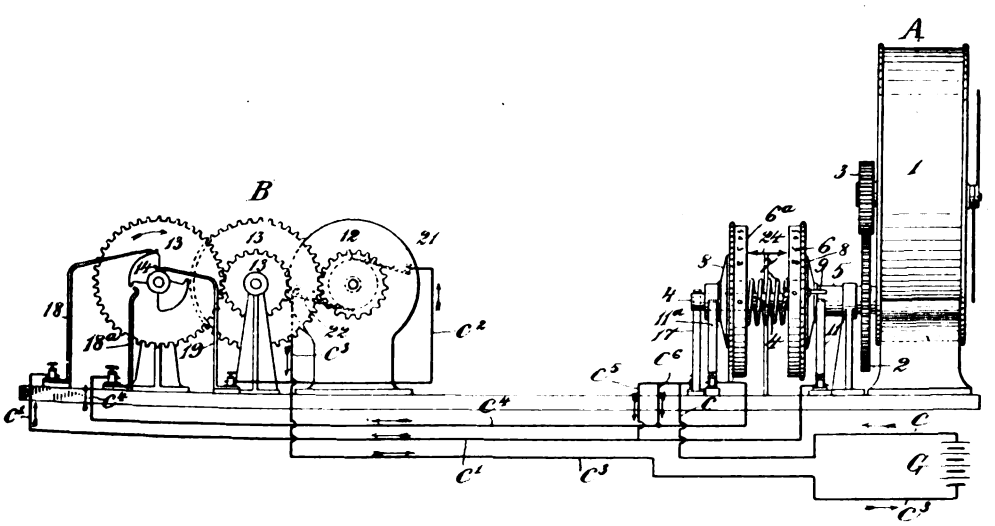

FIG. 2.—DIAGRAM OF CONNECTIONS, TROPP AUTOMATIC TIME SWITCH.

The device, which has been called a rotating circuit-breaker, is here shown as a wheel or cylinder of metal with two opposite quadrants cut out or removed; as it rotates the brush (18) remains in contact until the device makes a quarter of a complete rotation, when the brush falls or passes off and the circuit through the motor is thereby broken. The lights being now turned on and the motor at rest, the lights will remain turned on until the stud (9^a) on the wheel (6^a) shall come in contact with the spring terminal (11^a), when the current will flow to a brush (18^a), which will now be in contact with a segment of the circuit-breaker and thence through the motor as before. The motor is thus set in motion and turns off the lights, the circuit through the motor being broken when the brush (18^a) passes off from the segment of the breaker. There will always be one of the brushes (18) or (18ª) in contact with the breaker.

As stated, the wheels (6) (6ª) are free to be rotated by hand on the shaft so as to permit of setting the device for turning on and off the lights at certain hours; and, to facilitate this, there are hour graduations on the rims or peripheries of the wheels and a double-ended indicator or pointer (24) mounted on the base.

With the construction shown the switch (16) is rotative, but any other form of switch may be employed in the light circuit, as for example a knife-switch operated by a link or rod, which couples the arm of the switch to a crank on the rotary circuit-breaker. This device is semi-circular instead of quadrantal, as it requires a half rotation thereof to operate the switch for breaking the circuit through the motor.

In order that the circuit through the motor may be closed by hand at any time independently of the clock, switches for this purpose are provided, in branch circuits about the terminals (11) (11ª). It will be noted that, in the functions of the device, the motor circuit is branched, and the clock mechanism operates to close a break first in one branch and then in the other, alternately, and the motor acts, through the current changer, to break the supplying or active branch of the motor circuit and at the same time to close a break in the inactive branch. The clock mechanism completes the motor circuit through the branch closed at the switch or circuit-changer. The lamp circuit is wholly independent of the motor circuit in the electrical sense. They may be supplied from the same source or from different generators.

Bristol's Electric Time Recorder.

A new electric time recorder, designed to meet the demand for a simple and practical instrument to record automatically the occurrence and duration of certain operations such as the starting and stopping of machines, the opening and closing of valves, the duration of runs, the passing of trains, etc., has been brought out by the Bristol Company, Waterbury, Conn. With this instrument it is possible to record a number of different operations on the same chart, while the recorder may be located at a distance from the points at which the operations occur.

The use of these new Bristol recorders to indicate when the machines were started and stopped, how long they remained idle, and when they were started again is shown in Fig. 1, which is a reproduction of the record chart showing complete twenty-four-hour records of operation of two paper machines. This record shows the time and duration of each break and also the time required to wash the felts and put on new wires.

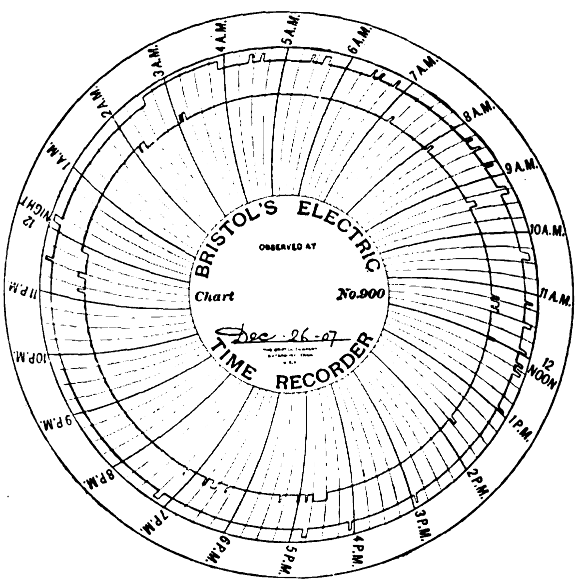

FIG. 1.—REPRODUCTION OF CHART MADE WITH BRISTOL'S ELECTRIC TIME RECORDER.

A recorder arranged to report operations at six different points is shown in Fig. 2. Each of the six pens of this instrument makes an independent record, continuously and automatically, and in this way six different operations may be recorded on the same chart. Each pen is actuated by an independent electromagnet and battery circuit, so arranged that closing the circuit causes the pen to move transversely on the chart.

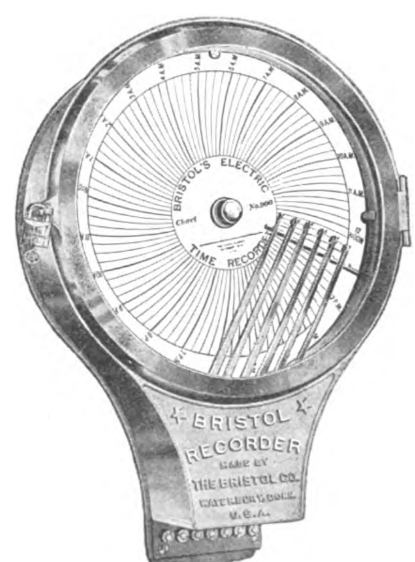

FIG. 2.—BRISTOL'S ELECTRIC TIME RECORDER.

Binding posts are provided at the base of the recorder, to which the small lead wires are attached. These wires may be of almost any length, as it is only necessary to have the operation to be recorded open or close the circuit whenever the motion occurs. These recorders are usually operated by a battery circuit, but any convenient circuit may be employed by the insertion of suitable lamps or other resistance to reduce the potential.

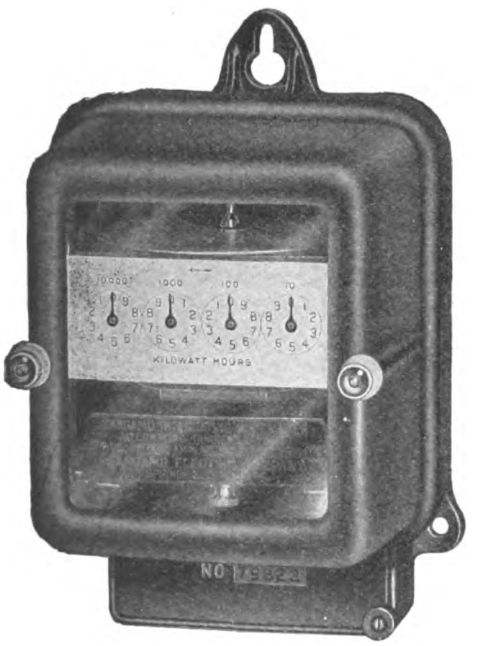
Electric-Lighting Data.

G. W. Armstrong, western manager of the Excello Arc Lamp Company, has begun the publication of an admirable series of bulletins designed to promote the understanding of the vital principles of flaming-arc-lamp operation and use, in order that prospective purchasers may be better able to judge of the merits of the various flaming arc lamps on the market. It is also purposed to furnish the electrical engineer with such data as may assist him in the selection and design of lighting installations. The collected issues of this bulletin, which is designated as "Excello Light," will form a textbook on the flaming arc lamp and its relation to illuminating engineering.

Mr. Armstrong is able to render valuable service to electrical and illuminating engineering through the medium of these bulletins, as only those data which are secured from the working out of actual, practical installations will be used in preparing the copy matter for each issue.

New Sangamo Wattmeters.

The Sangamo Electric Company, Springfield, Ill., has placed on the market two new types of its mercury wattmeters, designated as the Type D, direct current, and the Type F, alternating current. In October, 1904, the company offered its first mercury meter motor. This was adapted for direct current only, and embodied in its construction fundamental features which led the way to the further development of the Type D direct-current meter, which was put on the market a year later. The Type D meter, with a few detail improvements in construction, is the present very successful direct-current meter, and has attained a position of prominence as an accurate and efficient direct-current watt-hour meter.

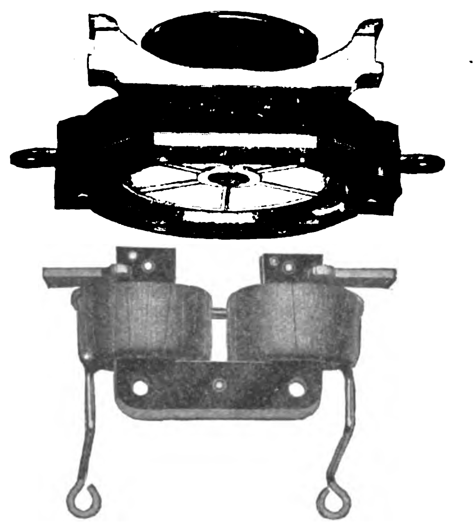


SERVICE TYPE SANGAMO METER, WITH NEW STYLE PRESSED STEEL CASE, FULL GLASS FRONT.

Following the general lines of construction and mode of operation of the Type D direct-current meter, the first alternating-current meter was brought out in the spring of 1906. Immediately following this meter the first transformer-type alternating-current meter, based on a principle entirely new, was developed. The company is now able to announce its perfected alternating-current watt-hour meter, the Type F.

The mercury meter consists essentially of a cylinder or disc-like motor element partly or entirely submerged in mercury, so that current can be led in and out from this element by the mercury acting as a contact maker, fixed metallic contacts being set in the walls of the chamber containing the mercury and the disc. The reaction of current passing radially or diametrically across the armature with a magnetic field properly set with respect to the armature will cause rotation, and this may be proportional to ampere-hours or watt-hours, and is available for either direct or alternating-current measurements.

When operated on direct current the main current, or a proportional part thereof, passes directly through the armature of the motor element. The poles of the field magnet are excited by a shunt coil. In the alternating-current meter the laminated field magnet is energized by a series winding, and the armature carries a large volume of current derived from a small potential transformer inside the motor, whose primary is connected across the line like the shunt coil of an induction meter. This transformer occupies the space back of the laminated magnet and its supporting bracket in such position that its heavy secondary winding can be conveniently and firmly connected



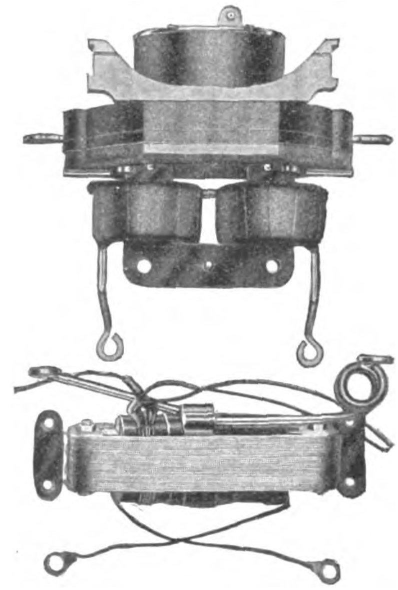
TYPE F MOTOR ELEMENT, ASSEMBLED, AND ALTERNATING-CURRENT LAMINATED MAGNET WITH SERIES COILS.

to the heavy copper contact ears of the disc chamber, while its small primary cables are in a position for connection to the binding posts below.

The armature or rotating element is made with a central dome or float, so that the total displacement when immersed in mercury is sufficient to buoy up the entire rotating system, including the damping disc outside of the mercury chamber, so that the difference between the true weight of the rotating system and this buoyancy effect is only about one-tenth of an ounce, this being, therefore, the effective weight or pressure upward against the top bearing jewel.

An improved light-load adjustment enables absolute zero of adjustment, no matter whether a meter is operated at normal voltage or at double voltage, as it is principally dependent upon the differential action between two small cable leads passing once in opposite directions around the laminated magnet in the alternating-current meter. The position of a clamp slider to the right or left causes relatively greater or less compensating current through the two windings, obtaining either a forward or slightly backward effect on no load by the slight initial magnetization given to the laminated magnet.

The curve of the Type F meter, on account of the improved construction of the series magnetic circuit, is straight from lightest loads to heavy overload, and as minimum initial compensation is required, the accuracy of the meter on wide range in voltage is exceptional. At one-tenth load the meter shows a variation not to exceed one-half to one per cent for



TYPE F MOTOR ELEMENT WITH LAMINATED MAGNET AND TRANSFORMER.

twenty per cent change in voltage from normal, and shows no error at half load or full load on the same change in voltage.

The Type F meter is practically independent of frequency without recalibration, as it shows no difference between sixty and twenty cycles, and an error of about one and one-half per cent at 133 cycles. It is also but little affected by change in temperature, a variation from normal accuracy of less than one per cent being caused by a change of thirty degrees Fahrenheit. The construction of the meter gives high torque—over fifty millimeter-grammes at full load, although with a shunt loss of but one and one-half watts at sixty cycles and two and one-half watts at twenty-five cycles, 110 volts. The potential drop between the series binding posts is about 0.4 of a volt in the five and ten-ampere meters, and less in the meters of larger capacities up to 150 amperes.

At present the greatest demand has been for meters with pressed-glass cases, but for special purposes cast-iron cases have been provided. The new Type F case has sides formed of pressed sheet-steel, and the front is of extra heavy double-strength glass, held in the case with screw clips, and cemented so as to be water and dust-tight. Beginning with December 1, the standard meter will be furnished with this new steel combination case.

All alternating-current meters up to and including 100 amperes capacity are provided with four binding posts, so that all direct-current meters, except those having 500-volt circuits, are similarly arranged in sizes up to eighty amperes. The alternating-current primary meters, when not of the switchboard type, have four posts arranged to use with current and potential transformers. All alternating-current meters larger than 100 amperes, and direct-current meters larger than eighty amperes, and direct-current meters of all capacities in the 500-volt type, have three binding posts—two series and one shunt.

The meter is nine and one-half inches high over the hanging lug and connecting box, six inches wide, and five inches deep, and weighs eleven pounds complete with the new steel combination case.

Large Industrial Orders of Electrical Machinery.

Continued evidence of returning industrial activity in various parts of the country is afforded by the mention of some of the recent orders taken by a large western manufacturer of electrical machinery, which will prove of especial interest at this time.

In Wisconsin, where authorities estimate there goes to waste at least 2,000,000 horsepower in unused waterpowers, large developments have recently been undertaken. Among the important hydraulic-turbine plants of this section contracted for with the Allis-Chalmers Company, Milwaukee, Wis., is that of the Northern Hydro-Electric Company, on the Peshtigo River. The initial installation will consist of five horizontal twin turbines, having each a capacity of 1,500 horsepower, or an aggregate of 7,500 horsepower, direct-connected to 1,000-kilowatt alternating-current generators, with exciter units of 400 kilowatts, combined capacity, all the machinery being of the Allis-Chalmers Company's build. This plant, which is near that of the Wausau Street Railway Company, now being equipped with hydro-electric units by the Allis-Chalmers Company, will be second in industrial importance for the "head-of-the-lakes country" only to the Great Northern Power Company's immense development, where 40,000 horsepower in Allis-Chalmers turbines—the largest single Francis wheels in the world—are in operation. The current generated on the Peshtigo River will be transmitted to Green Bay and neighboring towns, to be used for the operation of the street-railway system, commercial lighting and manufacturing purposes. Other large orders placed with the same company for hydroelectric plants include irrigation projects and central stations for power distribution in the Middle West, the plans of which have not yet been made public. Four noteworthy machines now being shipped from the Allis-Chalmers Company's works at West Allis are two 6,500-kilowatt generators of the waterwheel type for the Niagara Falls Hydraulic Power and Manufacturing Company, Niagara Falls, N. Y., and two of 2,500-kilowatt capacity for the Cazadero station of the Portland (Ore) Railway, Light and Power Company. These machines, which are designed for twenty-five and thirty-three cycles and speeds of 300 and 333 revolutions per minute, respectively, have recently shown some notable results on shop tests.

Among purchases of the steam turbines built by Allis-Chalmers Company are a 3,250-kilowatt machine, for the Pacific Mills at Lawrence, Mass., where already three of these turbines and generators are in service; several units of 1,000-kilowatts capacity for the Cleveland, Southwestern & Columbus Railway and the city of Nashville, Tenn., and a number of 500-kilowatt machines for the Webster & Southbridge Gas and Electric Company, the city of Danville, Va.; Pennsylvania Power Company; the city of Dunkirk, N. Y.; Willamette Valley Company, and the city of Frankfort, Ind. In addition to the main units these orders include exciters, power transformers, lighting transformers, condensers, circulating pumps, switchboards, etc., making complete power-plant equipments for the generation and distribution of alternating current.

The Industrial Lumber Company, Beaumont, Tex., is preparing to install two engine-type generators of 450 kilowatts capacity, with seventeen induction motors; the Johnson Chair Company of Chicago has bought a 500-kilowatt generator driven by a cross-compound engine; the city of Waverly, Iowa, recently ordered a belted unit of 225 kilowatts, and the American Sugar Refining Company has contracted for a 500-kilowatt generator driven by a high-duty engine.

The Allis-Chalmers Company has also received orders for a number of hoisting motors and engines, and for some very large pumping engines.

Ward Leonard Laboratory Rheostat.

The Ward Leonard Electric Company, Bronxville, N. Y., has designed a line of rheostats for laboratory service. The illustration shows a fifty-six-ampere capacity rheostat. The resistance portion is 10 inches by 12 inches by 15 inches, overall. The face-plate or controlling portion is only 14 inches by 8 inches. The controlling portion can be mounted on the test-table or inside the cover of a desk.

WARD-LEONARD LABORATORY RHEOSTAT

The resistance portion can be mounted on the side wall out of the way. There are but two wiring connections per switch from the resistance to the face-plate.

This rheostat can be used upon direct-current or alternating-current circuits as a non-inductive, zero-temperature-coefficient resistance. It is designed to give one-tenth-ampere divisions from one-tenth ampere to fifty-six amperes. Each switch is marked with the number of amperes that will flow when it only is closed. By closing the switches singly or in parallel, any desired load is obtained. Each resistance with its controlling switch is designed to be connected across the full line volts. As each resistance is designed to carry the full amperes that can be made to pass through it by the full line volts, burn-outs are impossible. The resistance elements are built up of Ward Leonard enameled resistance units. They are fireproof, strong, light, and are thoroughly protected against mechanical, electrical and chemical depreciation.

Current Electrical News

CONTINENTAL EUROPE.

PARIS, OCTOBER 24.—Since the telephone fire in Paris, the department has been taking active measures in order to set matters right in the shortest possible time. At present the temporary exchange is between the burned building and the Central Postoffice, and it has two floors for installing the apparatus. At present there are about a hundred connections a day made by the use of a number of small boards which have been placed in the building. The department ordered the new large multiple boards on September 26, at a cost of about $1,000,000. The contract stipulates that they are to be delivered by December 11, under a penalty of $1,200 for each day's delay. When the new boards are installed about 4,000 subscribers can be connected per day, so that the whole number of subscribers will have the use of their telephones within a week or so, according to the present outlook. In general, the manufacturers require fifteen months or two years to build multiple boards of this kind, but as in this case they are to be finished within two and one-half months, it will be seen that every effort is being made to finish the temporary exchange.

An important enterprise in Austria-Hungary is an electric railway in the region of Budapest, known as the Vacz-Budapest-Gödöllaer line. It is a suburban road in general, and a ninety-year concession for the line has been lately granted to a local firm known as the Electrical Enterprise Company. The road will make connection with the state railroad depot, and it will probably be run on the single-phase, high-tension system, should this prove to be suitable. The overhead line will be worked at 3,000 volts, using a number of safety devices. Four electric locomotives are to be used on the line, as well as a number of motor cars.

At Martigny, where the valley of the Dranse River joins that of the Rhone, there is a hydraulic plant of large size which has been erected quite recently. It is operated by the Société d'Electrochemie, which has a capital of $1,000,000, and now controls six hydraulic plants in Switzerland and France for manufacturing carbide and other chemical products. There is an extensive carbide works at Martigny in connection with the turbine plant. The latter now has installed nearly 15,000 horsepower in alternators and direct-current generators. One part of the outfit consists of five 750-kilowatt Thury generators, which furnish energy at 150 or 300 volts for the electrolytic work, the current in this case being 5,000 amperes or less for each machine. There are also installed three 2,500-horsepower, three-phase alternators which supply current over a 10,000-volt power line to a second carbide plant lying a few miles off and operated by the same company, also to a carbide works in the same region, which is owned by the Swiss Nitrous Product Company. A set of small generators develops current for the local tramway line.

Current for the Martigny-Chatelard electric road is furnished from a hydraulic plant which is located at Vernayaz, in the Rhone Valley. This plant is most unique, and there is certainly not another one like it in the county. It is placed high up in the side of the mountain at a point lying above the celebrated waterfall of the Pissevache. The latter springs from the abrupt mountain slope and falls in a cascade into the valley, being more than 200 feet in height. The hydraulic plant is placed in a chamber cut out of the solid rock in the side of the gorge, which lies above the fall, and the penstocks lead to a point which is much higher up in the mountain, where the water supply is secured. After passing by the turbines the water is returned to the cascade below, so as not to interfere with the appearance of the latter. In the plant there are installed six turbine groups which supply the current for the Martigny-Chatelard electric road and also for a large carbide works which is located at Vernayaz. The latter plant is controlled by the Stächelin Company, which also owns a carbide works in another point along the Rhone Valley at Aproz. For this second works a separate hydraulic plant is used.

Recently I had occasion to visit the work upon the Lötschberg tunnel at the south end. The scope of this great undertaking is perhaps not as generally known as it should be, but in fact the work ranks but little below that of the Simplon. The object of the tunnel is to run directly through the mountains of the Bernese Oberland, and thus to give a direct route from the north to the south of Switzerland. The new railroad section, which will be electrically operated, connects with the Federal railroad on the north side of the mountains at Frutigen and enters the tunnel near Kandersteg, coming out at the south end near Goppenstein. The tunnel is 13.7 kilometers in length (8.5 miles), and the south end lies about 12 miles from the north end of the Simplon Tunnel, the latter being further along the Rhone Valley. A very extensive plant is being erected at the south end of the Lötschberg Tunnel, and there are from 1,200 to 1,500 workmen employed in the enterprise. At present the rock-drilling is being carried on at the rate of forty feet per day by compressed-air drills. The power plant at the tunnel receives current from a distant turbine station, and there are now four three-phase motors which drive the air compressors. The plant has a capacity of 1,200 horsepower for the compressors alone, using motors of the Alioth system.

A. DE C.

GREAT BRITAIN.

LONDON, OCTOBER 30.—At the first annual meeting of the Victoria Falls Power Company today some interesting statements were made with regard to the prospects and policy of the company. It was made quite clear that it is not the intention to start upon the erection of an overhead transmission line from Victoria Falls to the Transvaal at an early date. In fact, it was plainly indicated that the company's chief consulting engineer, Mr. Ralph D. Mershon, of New York, was still of the opinion that the limits of voltage at which such transmissions can be operated have by no means been reached, and that in the meantime it is cheaper to continue to supply from a steam-driven station than to make use of the water power. Further, the company's engineers seem to have been agreeably surprised at the cheapness with which production can be carried on by coal in the Transvaal, the results having been lower than the estimates. There is a single possibility that remains, however, by which the station may be built at the Falls: it is by the centralization of industries in the immediate neighborhood, a development which the company is trying hard to bring into existence.

A definite step forward has now been made with the London electric power bills, for in the House of Commons on Monday the committee which will soon commence consideration of the bulk supply scheme was instructed to include the name of the London County Council as the purchasing authority. The government has given its consent to this bill on the requirement that certain modifications are made, and it is certain that if the promoters can see their way to accept these, the bill will go forward.

The meetings of the International Conference on Electrical Units and Standards have now been concluded and the final report of the technical committee is in preparation. The International Electrotechnical Commission, which has been created as the result of the St. Louis Congress of 1904, has also met this week and named Prof. Elihu Thomson president. As the International Conference is in favor of appointing a permanent committee, with much the same objects as the Electrotechnical Commission, there appears the possibility that some scheme of combination will have to be evolved in order to avoid duplication of work.

With the approach of the absorption of the National Telephone Company by the state, the directors have concluded that it will not pay them to continue to carry out construction work which will not be in productive use during the next three years. In consequence, a large number of employes are being dismissed and the matter has been the subject of discussion in the House of Commons.

The City of London Corporation at this late day is sending a deputation to the Continent to inspect various systems of street lighting. At present the city of London is lighted by a mixture of ancient and modern electric arc lamps and a few types of gas lighting.

The British Westinghouse Company has just received an order for the equipment of a large power station for the Buenos Ayres & Pacific Railway Company in connection with the public lighting of Bahia Blanca, Argentine Republic. J. F. C. Snell of London is the consulting engineer. G.

EASTERN CANADA.

OTTAWA, NOVEMBER 7.—English capitalists are promoting the organization of a company for the institution of a motor-bus service in the city of Toronto, to compete with the Toronto Street Railway. The proposed capital of the company is $2,000,000. Fifty motor buses will be built, each with accommodation for thirty-six passengers, and regular routes of service will be arranged.

The first sod for the construction of the Niagara Falls transmission lines of the Ontario hydro-electric power commission will be turned on November 18. It is planned to make the occasion a ceremonial one. The construction work will start near the city of Toronto.

The city of Brantford, Ont., will vote on the question of entering into a contract with the Hydro-Electric Commission in January next. Offers from the commission and from the Cataract Power Company of Hamilton were considered, and although the latter concern underbid the commission, nevertheless, in some particulars, the conditions the company stipulated were deemed disadvantageous.

The Ottawa Electric Railway Company has been experimenting with some pay-as-you-enter cars. They have proved so satisfactory to the company and the public that the company will adopt this style of car on its principal streets in the near future.

The Montreal Light, Heat and Power Company has refused to renew the street-lighting contract with the city at the current rate. The company claims that it is losing money on the present contract price, which is $60 per lamp. The company is demanding $75 per lamp.

The Montreal Street Railway Company's annual report shows that the road, during the last year, carried 90,746,032 passengers, the average earnings per passenger being 3.96 cents. There were, however, 30,343,113 transfers issued, so that in reality 121,089,145 passengers were carried, thus reducing the earnings per passenger to 2.97 cents. The earnings were $3,677,432, as compared with $2,220,787 five years ago. The total number of shareholders is 1,526. Hon. L. J. Forget was re-elected president, and W. G. Ross, managing director.

Very encouraging results have been reported at Canadian Pacific Railway headquarters, from the experiments that have been made with a view to the introduction of electricity as a motive power for the operation of trains in the mountain section of the system. The electrification of the whole mountain section, which is upward of 600 miles in length, may be undertaken in the near future, but, while the tests are satisfactory, they have not gone far enough yet to justify a large expenditure.

A project under way aims to connect Ottawa with Morrisburg by electric railway. This includes the building of a new line from Morrisburg to a point on the present Ottawa and New York Railway, and the adoption of electricity as a motive power on the entire line, which will include about twenty miles of the present Ottawa and New York system. The enterprise is being promoted by J. Wesley Allison of Morrisburg. It is given out that the necessary capital for the project is guaranteed, and that there only remains the surveying of about fifty miles of country and the granting of a charter by the government of Canada to allow building operations to begin immediately. The total length of the new electric line will be about seventy-five miles. W.

WESTERN CANADA.

WINNIPEG, NOVEMBER 7.—The first construction work on the civic power plant at Lac du Bonnet, being built by the city of Winnipeg, has been commenced, and it is expected all the excavating for the plant proper will be completed this fall. The tramway, bridges and several other works in connection with the plant have been finished. It is believed that the power plant at Lac du Bonnet will mean the removal of a number of eastern Canadian manufacturers to Winnipeg.

According to statements by officials, a part of the New Westminster-Chilliwac line of the British Columbia Electric Street Railroad Company will be in operation between New Westminster and Cloverdale by the end of the year.

The City Council of Port Arthur, Ontario, has canceled the contract recently made with the Kaministiqua Power Company of Fort William, Ont., for the supply of 400 horsepower for civic purposes. It is alleged that when the company had secured the contract it was used to influence the Ontario government in order to obtain power privileges at Dog Lake Falls. Port Arthur, through J. J. Carrick, mayor, canceled the contract, as the city had been endeavoring to secure power rights at the same falls.

The capital stock of the Russell Telephone Company has been increased from $5,000 to $25,000 for the purpose of building a number of extensions. The head office of the company is at Russell, Man.

The municipal authorities at Port Arthur, Ont., have raised the telephone rates from $1 and $2 per month to $1.25 and $2.50 per month for residence and business telephones, respectively, explaining that this was found necessary to meet the expenses of the department. The City Council has asked the telephone commissioners at Fort William to raise their rates to the same figure.

Five hundred men are now at work on the power dam near Fort Francis, Ont., for the Backus-Brooks syndicate, and Mr. Richardson, the general superintendent, expects to have the dam completed before the end of the year.

The Oxbow Telephone Company, Oxbow, Sask., announces that a number of extensions to the system will be made.

Telephones are becoming very popular in the farming communities of Manitoba, and already this season the government has installed over 1,200 farmers' phones, in addition to some 1,800 new connections in cities and towns. There are still a large number of applications for telephones on hand, many of which will not be installed until next spring. The Manitoba Telephone Commission is now busy preparing requisitions for supplies for 1909, which will be a very busy season, as the government has decided upon the construction of a large number of rural and long-distance lines. Among the items required for next year are 25,000 poles, tenders for which are now being called. Orrin F. French is chief engineer to the commission, with headquarters at Winnipeg, Man.

This year the employes of the British Columbia Electric Street Railroad Company will receive $40,000 under the pension system inaugurated by the company in 1903. Each employe who has been with the company for a year up to July 1, 1908, will receive $66.78, irrespective of his position with the company. The sum divisible is one-third of the balance available for dividend paying after four per cent has been paid on the common stock. As showing the growth of the company, it may be mentioned that the former bonuses were: 1903, $25; 1904, $35; 1905, $40; 1906, $45; 1907, $63, and 1908, $66.78. At the annual meeting of the company held in London, England, on November 4, a dividend of eight per cent was declared on ordinary stock. R.

IMPORTANT DEVELOPMENTS.

TO ELECTRIFY MOUNTAIN RAILROAD IN PERU—The Peruvian Corporation has decided to electrify the Central Railroad of Peru, which connects Callao with Oroya in the mountains. This will make possible a great increase in the traffic handled.

NEW TRANSFORMER HOUSE FOR CANADIAN NIAGARA POWER COMPANY—The new transformer house of the Canadian Niagara Power Company is completed and the installation of the three gigantic transformers having been finished last week, increased the output from 20,000 horsepower to 32,000 horse-power. The new structure is an addition to the old transformer house, and the machines that have been placed therein will be put in operation early in November with the new transmission line which has just been strung to Fort Erie, where it crosses to a point near Ferry Street, Buffalo.

SOUTHERN PACIFIC RAILROAD PREPARES TO ELECTRIFY—The Southern Pacific Railroad Company is making preparations for changing its motive power from steam to electricity, and orders for much of the equipment have already been filed. It is the intention to crowd the installation of this equipment as fast as possible. The company is already commencing the erection of a large power plant near the tidal canal at Fruitvale, and will install several substations at other points suitable to the distribution of power for the different suburban lines. The Berkeley end of the electrification is expected to cost $2,000,000.

RECEIVERS FOR HUDSON RIVER COMPANIES—As receivers for the Hudson River Electric Power Company against which bankruptcy proceedings have been begun, as noted last week, Judge Ray has appointed Charles W. Andrews, of Syracuse; George W. Dunn, of Binghamton, and Milton Delano, of Canastota, N. Y. The corporation was organized in 1903, and controls the Hudson River Water Power Company, Hudson River Electric Company and Hudson River Power Transmission Company, together with various sub-companies owned by the latter two, supplying central and eastern New York State with power. The authorized capital stock was $10,000,000, of which $5,390,000 was issued. The total funded debt of the corporation, according to its last statement, was $9,683,500. Net earnings for 1907 were $486,200. Messrs. Andrews, Dunn and Delano were required to give bonds in the amount of $100,000 each as receivers.

OPERATION OF WISCONSIN'S NEW UTILITY LAW DISTRIBUTES CORPORATION TAXES—The Wisconsin State Tax Commission, acting as a state board of assessment of street-railway companies, has announced the assessment of these properties, under the new law enacted by the last legislature, providing for taxing these public utilities according to the ad-valorem system by the State Tax Commission rather than under the license-fee system locally. Heretofore these companies were assessed locally and twelve per cent of the tax was turned over to the state and eighty-eight per cent retained locally. Under the new law the State Tax Commission makes the assessment, the state collects the tax and distributes eighty-five per cent thereof among the localities through which the railway line runs, the local distribution being made in proportion to the earnings of the line in each locality. Twenty-four companies are assessed and taxed under this system. The total of the preliminary assessment of these properties was $36,098,000, and the total tax levied is $390,637.75.

COLORADO POWER COMPANY WINS LONG-CONTESTED SITE—The Denver Power and Irrigation Company has won a fight of several years' duration for the right to a mammoth irrigation and power site in the South Platte Canyon, extending from Eagle Rock to a point above Decker's summer resort, a distance of fourteen miles, and the estimated cost of which is $10,000,000. The Two Forks Reservoir Company, backed by C. P. Allen and J. E. Maloney, and the High Line Reservoir Company, backed by W. E. Bates, filed on the same stretch of territory as did the Denver company and half a dozen railroad companies. The dispute as to who was entitled to the right-of-way was decided by Fred Dennett, commissioner of the general land office, and has been received in full by the Denver government land office, and the interested parties. The sites all start where the north and south forks of the Platte join, thirty-one miles from Denver, at the town of South Platte. The Denver Power and Irrigation Company has spent about $100,000 in the preliminary work.

LOWER CABLE MESSAGE RATE URGED BY CHAMPION OF TWO-CENT TRANSATLANTIC POSTAGE—The first stage in the campaign for the reduction of the world's cable rate will be reached next week, when the earl of Jersey will preside at a meeting called to consider ways and means by which adequate support may be given to the movement for cheaper rates in international electric communication. The moving spirit in the project, John Henniker Heaton, whose efforts were largely responsible for the two-cent postal tariff between America and Great Britain, says in the course of time a rate of two cents a word will obtain for cable messages. His proposition is that the British and American governments jointly acquire the property rights of the existing cable companies at a fair valuation and thereby establish a common state monopoly of cable communication. At present, Heaton says, the cable-carrying capacity amounts to 300,000,000 words, and only 250,000,000 are sent at twenty-four cents a word. If the cables were owned by the state and employed to their full capacity, he declares, it would be possible to establish a tariff of two cents a word.

GREAT WESTERN POWER COMPANY TO SELL THROUGH PACIFIC GAS AND ELECTRIC COMPANY—The Great Western Power Company has reached an agreement with the Pacific Gas and Electric Company by which the power company will not retail its product, but will sell directly to the distributing company. The territory served by the two companies extends from the northern part of California to Santa Cruz. It is understood that the new company will not compete in towns or cities of northern or central California until it is more firmly established. The contract with the Pacific Gas and Electric Company is temporary, but may ultimately result in a merger of the two organizations. The Great Western is at present endeavoring to secure a franchise to operate in Sacramento. The Pacific Gas and Electric Company is the parent corporation of thirty concerns, including the California Gas and Electric and the San Francisco Gas and Electric. The Pacific company operates in twenty-nine counties in the state, supplies current to twelve electric railroads and sells power to forty-three different cities and towns in California. It controls all the business about the bay cities and the greater part of the business in the north.

ELECTRIC LIGHTING.

GREENVILLE, KY.—The Greenville Light and Water Company will extend its lighting circuits, having voted to offer $12,000 in bonds.

MONDOVI, WIS.—The Mondovi Milling Company and the Mondovi Electric Light Company have consolidated and will build a new electric-light plant.

GOLIAD, TEX.—Joel and Jasper Shaper have purchased the interests of the Goliad Water and Light Company and will conduct the company in the future.

GADSDEN, ALA.—A franchise has been granted to the Etowah Light and Power Company, Attalla, Ala., to furnish electricity for commercial purposes.

FEDERALSBURG, MD.—The Idlewild Electric Light and Power Company, incorporated to develop waterpower properties, has effected permanent organization, with John F. Disharoon, J. B. Wright and E. E. Goslin as directors.

KNOXVILLE, TENN.—The permanent illumination of Gay street, after the design of recent temporary carnival lighting, has been urged by a committee of local merchants, which proposes to put three or four arches across the street in every square.

ELECTRIC RAILWAYS.

GREEN BAY, WIS.—The Bay Shore Street Railway Company has been incorporated by Fred A. Rahr and others.

FRANKFORT, KY.—An interurban line from Frankfort to Lawrenceburg is the next electric traction line planned for the Bluegrass district.

SAGINAW, MICH.—Electric cars will be running between Saginaw and Detroit by January 1, officials of the Flint and Saginaw Electric Railway declare.

JACKSONVILLE, ILL.—Construction work will soon begin on the Alton, Jacksonville & Peoria electric line. Four miles of the road is completed near Alton.

SPOTTSYLVANIA, VA.—A conference has been held by business men looking to the formation of a joint stock company, whose object is to build an electric-railway line to run from Fredericksburg to Spottsylvania and from there to Mineral City, in Louisa County. This railway would pass through a section of the country rich in minerals.

PERSONAL MENTION.

CHANCELLOR JAMES R. DAY, of Syracuse University, sailed for Europe last Saturday on the Königin Louise.

MR. W. G. MELOON is to assume the management of the Twin State Gas and Electric Company, of Dover, N. H.

MR. S. J. DUNCAN, who has been superintendent of the Northwestern Electric Heat and Power Company, at Kearney, Neb., has resigned and will take up new work in Oklahoma.

MR. E. W. McCLENNAN, formerly manager for the Bell Telephone Company at Orillia, Ont., has been appointed traffic manager, with headquarters at Winnipeg, for the Manitoba Telephone Commission.

MR. R. E. HUNT, who had been superintendent of railway service for the Utah Light and Railway Company, at Salt Lake City, Utah, has been promoted to the position of assistant general manager of the company.

MR. ROBERT HOWES, formerly with the Washington Waterpower Company of Spokane, is at Vancouver, B. C., to superintend the construction of the Chilliwac branch of the British Columbia Electric Street Railroad Company.

MR. HARRY D. CRANSTON, a graduate of the electrical engineering department of the Ohio State University, has accepted a position as superintendent of the municipal electric-lighting and waterworks plants of Rockwood, Tenn.

MR. HERBERT E. PLASS, general manager of the Howard Miniature Lamp Company, Newark, N. J., is stopping in Chicago on his return from a trip to the Pacific Coast, in company with E. H. Haughton, manager of the Chicago Bryan-Marsh Company.

MR. H. P. JAMES, formerly electrical engineer for the Bryant Electric Company, has taken a position as sales manager for a new line of push-button specialties recently placed on the market by the Cutler-Hammer Manufacturing Company, of Milwaukee, Wis.

MR. OREN ROOT, manager of the Metropolitan street-railway system, New York city, married Miss Ada De Acosta on the afternoon of November 5, at the bride's home in New York. The Rev. Father Patrick Daly, of Poughkeepsie, N. Y., performed the ceremony.

MR. J. D. DOWNER, who was for a number of years in the service of the subscription department of the Western Electrician, has become sales manager for the Kimble Electric Company, 617 West Adams Street, Chicago, manufacturer of variable-speed, single-phase, alternating-current motors.

DR and MRS. LEE DeFOREST returned from Europe on the steamship Lusitania, reaching New York October 30, after a trip on the Continent, during which France, Italy, Germany and England were visited on business in connection with Dr. DeForest's wireless telegraph and telephone interests.

CHARLES H. FISH, agent for fifteen years for the Cocheco Cotton Mills, at Dover, N. H., has resigned and will accept a position of responsibility, it is understood, with the American Telephone and Telegraph Company. He is a brother of Frederick P. Fish, former president of the telephone company.

MESSRS. E. A. ENNIS and E. J. NELSON, formerly with the Mergenthaler Linotype Company as chief clerk and assistant chief clerk, respectively, have formed a business association as factory systematizers and cost men at 173 York Street, Jersey City, N. J., under the firm name of Ennis & Nelson.

MR. WILLIAM P. BAILEY, who has been superintendent of the Michigan City division of the Chicago, South Bend & Northern Indiana Electric Railway, has tendered his resignation and will return to the employ of the Terre Haute, Indianapolis & Eastern Railway, making his headquarters at Indianapolis.

PROF. F. B. BADT, president of F. B. Badt & Co., 1504 Monadnock Block, has returned from New York city, where he had gone for a couple of weeks to visit his home offices and works, viz., the Weston Electrical Instrument Company, Waverly Park, Newark, N. J., and the Ward Leonard Electric Company, Bronxville, N. Y. It is understood that he closed some new selling agencies, one of which is for the well-known "Stave" flaming arc lamp. He expects a brisk business in 1909 and is preparing to meet this enlarged demand. Professor Badt has entirely recovered from his recent illnesses, his health now seems to be all that can be desired, and his many friends are glad to see him back in Chicago.

MR. HUGH A. BROWN has resigned from the Crocker-Wheeler Company, manufacturers and electrical engineers, to whose Chicago office he had been attached for several years. He now takes up the work of sales manager for the Rockaway Coaster Company of Cincinnati, in which he has a substantial interest.

DR. CHARLES WILLIAM ELIOT, president of Harvard University, has resigned, his resignation to take effect on May 19 next. The announcement of the resignation was made at a special meeting of the Board of Overseers. It is stated that the board with the utmost difficulty arrived at the conclusion that a proper regard for the president's wishes required it to relieve him of the arduous duties of his office. Charles William Eliot was born in Boston, Mass., March 20, 1834. His father was Samuel A. Eliot, for many years treasurer of Harvard University, and several times mayor of Boston. Dr. Eliot entered Harvard at the age of fifteen, and was graduated in 1853. Shortly after his graduation he returned to the college, where he spent nine years in various offices of instruction. From 1864 until 1865 he was abroad, making a particular study of foreign methods of education. While abroad he was elected professor of analytical chemistry and metallurgy in the Massachusetts Institute of Technology. He returned to Europe in 1867 again, studying educational subjects. Two years later he was called to the presidency of Harvard University. This was the first time that a layman had been called to head the institution, and his inaugural address, based upon the highest ideals of nonsectarian education, was received with astonishment.

NEW MANUFACTURING COMPANIES.

BOSTON, MASS.—The Edwin C. Lewis Company has been incorporated with a capital stock of $75,000 to manufacture electrical apparatus. E. C. Lewis is president and treasurer.

THE BROWNRIGG & STEVENSON COMPANY, New York, has incorporated with a capital stock of $10,000, as steam and electrical engineers and general contractors. The members of the firm are C. Maxwell Stevenson and M. Wilson, 29 Broadway, and Robert E. Samuels, 229 Broadway, New York.

THE IOWA CONSTRUCTION COMPANY, Eldora, Iowa, has been incorporated by Henry S. Osborne and others, with a capital stock of $10,000, to construct railways between Waterloo, Perry and Ames.

NEW YORK, N. Y.—The Excelsior Storage Battery Company, New York, N. Y., has been incorporated with a capital stock of $10,000. The directors are Philip Hornwitz, Bella Robins and Aaron A. Feinberg, New York, N. Y.

NIAGARA FALLS, ONTARIO—The American Electric Furnace Company, which has built a plant in this city, has been incorporated as a Canadian company, the provisional directors being Thomas Rawlands, W. H. McGuire, F. W. Griffiths, Alice L. Johnson and Charles S. Peaslee. The company manufactures certain kinds of electric furnaces, which are used for smelting, concentrating and refining ores and metals. The company has branches in Norway and England and in the United States. The Canadian company is capitalized at $50,000.

THE AMERICAN ELECTRIC SMELTING AND ENGINEERING COMPANY has been incorporated in St. Louis, Mo., with a capital stock of $50,000, in Chicago. The principal incorporator is Albert E. Greene of Chicago, who is a graduate of the Massachusetts Institute of Technology and has devoted his attention to electric furnaces, perfecting one which the company will manufacture and place on the market.

NEW PUBLICATIONS.

"THE MODIFICATION OF ILLINOIS COAL BY LOW TEMPERATURE DISTILLATION," by S. W. Parr and C. K. Francis, has been issued in pamphlet form as a bulletin of the University of Illinois at Urbana. The paper is a report of a series of experiments carried on by the chemical department of the university since 1902 for the purpose of effecting a chemical change in the ordinary coals of Illinois, such as to modify or prevent the production of smoke.

OBITUARIES.

MR. ARTHUR W. SHELTON, president of the Rhinelander Power Company and the White River Power Company of Ashland, Wis., died at Rhinelander, November 1. Mr. Shelton was a wraduate of Wisconsin University of the class of 1883 and was prominently identified with leading manufacturing interests, in addition to his connection with the electrical power industry.

MR. HENRY A. BUTTERS, a wealthy capitalist, prominently identified with the construction of a number of electric railways in the Pacific Coast, who died, as announced last week, at Berkeley, Cal., of acute congestion of the lungs, was a personal friend of the late Cecil Rhodes and his partner in several mining enterprises, the builder of the first electric tramways in South Africa, Switzerland, Mexico and South America and the president and founder of the Northern Electric Company of California.

MR. C. E. TRUMP, president of the Novelty Electric Company, of Philadelphia, and one of the pioneer electrical men of the country, died suddenly from affectation of the heart at his residence in Germantown, Philadelphia, Pa., Friday, November 6. Mr. Trump had been suffering slightly for a few months from muscular disturbances of the heart, but no dangerous symptoms had developed, and his sudden death came as a great shock to his family and friends. His funeral occurred from his late residence Monday, November 9, a number of friends from New York city attending the ceremonies. Mr. Trump was prominent in electrical circles in Philadelphia, and a regular attendant of many of the National conventions. He was one of the first to enter the field of electrical supplies and manufacturing, and has been quite successful in this line. His son, Mr. C. N. Trump, will continue as the active head of the company.

PROF. WILLIAM EDWARD AYRTON, the British electrical engineer and physicist, died in London, November 8, at the age of sixty-one years. Born in 1847, young Ayrton gained numerous prizes during his earlier schooling, and in 1867 received with honors the degree of B. A. It was while in the Indian Telegraph Service that he was sent to study electrical engineering with the late Lord Kelvin, and later became electrical superintendent of the government telegraph department. In 1872 he was in charge of the manufacture of the Great Western telegraph cable at Micham, representing the engineers, Lord Kelvin and Prof. Fleeming Jenkin. Until 1879 Professor Ayrton occupied the chair of natural philosophy and telegraphy at the Imperial College of Engineering, Japan, which was then the largest English-speaking technical school in existence. Later he was professor of applied physics at the London Technical College, the Central Technical College, South Kensington, and the City and Guilds of London Institute, of which last he also became dean. Professor Ayrton was elected a fellow of the Royal Society in 1881 and is a past-president of the Physical Society and Institution of Electrical Engineers. He visited the United States in 1893 as one of the British delegates to the Electrical Congress at Chicago. Professor Ayrton was a joint author in the invention of well-known ammeters, voltmeters, wattmeters, the ohmmeter, dispersion photometer, dynamometer and secohmmeter and the system of automatic electric transport known as "telpherage." More than one hundred papers by Professor Ayrton have been published in the proceedings of various learned scientific societies. These are on a variety of subjects ranging from abstract scientific topics to the practical uses of gas and steam engines and electric motors.

ELECTRICAL SECURITIES.

Immediately following the election there was apparent a considerable advance in activity, and with reports of the resumption of full-time operations in many industrial quarters, where for the past six months there has been considerable depression, the market rallied and put on an air of prosperous expectancy. While from many directions it was indicated prior to the election that the result had been anticipated by the improvement which had been brought about within the last two or three months, this hardly seems to be the case.

The regular quarterly guaranteed dividend of 1¼ per cent on the stock of the American Telegraph and Cable Company will be paid December 1. Books close November 15, and reopen December 2.

ELECTRICAL SECURITIES FOR THE WEEK ENDED NOVEMBER 7.

New York:	*Closing.*
Allis-Chalmers common	13¼
Allis-Chalmers preferred	45⅛
Brooklyn Rapid Transit	52½
Consolidated Gas	145½
General Electric	153¾
Interborough-Metropolitan common	10⅛
Interborough-Metropolitan preferred	30¼
Kings County Electric	125
Mackay Companies (Postal Telegraph and Cables) common	75½
Mackay Companies (Postal Telegraph and Cables) preferred	70
Manhattan Elevated	139⅛
Metropolitan Street Railway	24
New York & New Jersey Telephone	114
Western Union	63
Westinghouse Mfg. Company	91

At the annual meeting of the Allis-Chalmers Company, K. K. Knapp was elected a director, succeeding J. F. Neave. Other directors were re-elected.

At a meeting of the trustees of the Mackay Companies, H. V. Meredith, of the Bank of Montreal, Montreal, was elected a trustee. In view of the large holdings of Mackay Companies' shares, preferred and common, held throughout Canada, it was felt that Montreal should be represented on the board of trustees. The Mackay Companies have now two representatives in Canada, Mr. Meredith and R. T. Smith, of the firm of Osler & Hammond, Toronto.

Boston:	*Closing.*
American Telephone and Telegraph	129½
Edison Electric Illuminating	247
Massachusetts Electric	57¾
New England Telephone	124
Western Telephone and Telegraph preferred	70
Philadelphia:	*Closing.*
Electric Company of America	9⅞
Electric Storage Battery common	39
Electric Storage Battery preferred	39
Philadelphia Electric	12
Philadelphia Rapid Transit	22½
United Gas Improvement	89¼
Chicago:	*Closing.*
Chicago Telephone	125
Commonwealth Edison	108
Metropolitan Elevated preferred	42⅛
National Carbon common	72½
National Carbon preferred	111

Metropolitan and South Side Elevated traffic last month showed the largest decrease this year. Northwestern Elevated's gain was very small. The total for the three was 11,867,623 passengers or a loss of 301,478, though 1,260,000 more than September.

TELEPHONE AND TELEGRAPH.

HOLLIS, OKLA.—The Hollis Telephone Company has been incorporated with a capital stock of $20,000.

HOLLAND, TEX.—The Rural Telephone Company, of Holland, has been chartered by J. H. Edwards and others.

KANSAS, OKLA.—The Northeast Oklahoma Telephone Company has been incorporated by D. L. Bird and others.

PARADISE, ARK.—The Paradise & Raymond City Telephone Company has been incorporated with a capital of $20,000.

DELHI, LA.—The West Carroll Telephone and Improvement Company has been incorporated with a capital of $10,000.

WEIMAR, TEX.—Farmers living south of Weimar have joined forces and are building a telephone line to connect their farms with the local exchange.

STRAUSSTOWN, PA.—The Womelsdorf and Rehrersburg Rural Telephone Company, organized with $5,000 capital, will construct lines reaching Mt. Ætna, Millersburg, Rehrersburg, Host, Krick's Mill, Bernville, Strausstown and North Heidelburg. A. M. Miller, Stroudsburg, is president of the company.

PLYMOUTH, MICH.—The Wayne County Telephone Company, a $50,000 corporation, has filed articles of association. Of the authorized capital, $28,000 has been paid in cash. The directors of the company, all residents of Plymouth, are headed by Edward C. Hough.

INDUSTRIAL ITEMS.

THE PACIFIC ELECTRIC HEATING COMPANY, Ontario, Cal., in the October issue of "Hot Points," calls attention to a number of interesting features concerning electric heating and cooking devices.

ROSSITER, MACGOVERN & COMPANY, New York, dealers in electrical machinery, have issued their October stock list, which catalogues an extensive stock of electrical machinery, boilers, engines, dynamos and motors.

THE MURPHY ELECTRICITY RECTIFIER COMPANY, Rochester, N. Y., has prepared working drawings and specifications, upon which bids will be received for the manufacture of its apparatus. These specifications will be furnished upon application.

THE KEYSTONE ELECTRICAL INSTRUMENT COMPANY, Philadelphia, Pa., has removed its New York office to the Hudson Terminal buildings, Church Street. Hereafter this office will be in charge of G. M. Dyott, formerly of the company's Pittsburg office.

THE CLARENCE VREDENBURG COMPANY, specialist in advertising, Monadnock Block, Chicago, has mailed to its friends copies of a handsome calendar of a subject appropriate to electric lighting. The calendar sheets will be useful from the present month until April, 1909.

THE CENTRAL ELECTRIC COMPANY, Chicago, Ill., is distributing a twenty-page circular devoted to a description of direct and alternating-current vibratory massage motors. Literature is also being distributed by the company describing the Samson strand or messenger wire grip and a new adjustable telephone bracket.

THE GREGORY ELECTRIC COMPANY, Chicago, Ill., supplements its regular bargain sheet for November, listing a large stock of generators, motors, engines, lamps, transformers, switchboards and supplies, with a dealers' list of machines offered as received without being overhauled, at special bargains and for immediate delivery.

THE PETTINGELL-ANDREWS COMPANY, Boston, Mass., has recently published a new catalogue of ignition specialties for internal-combustion engines. This covers spark coils for automobile and motor-boat service, spark plugs, spark indicators, switches and batteries, most of which are made by the Jacobson-Brandow Company, Pittsfield, Mass., for which it is the exclusive selling agent.

THE WARD LEONARD ELECTRIC COMPANY, Bronxville, N. Y., is distributing a bulletin covering its laboratory rheostats showing a fifty-six-ampere size, giving ampere divisions from 0.1 to fifty-six amperes, which, it is declared, cannot be so manipulated as to cause a "burn-out." This bulletin contains H. Ward Leonard's table of equivalent values of electrical and mechanical units.

THE NERNST LAMP COMPANY, Pittsburg, Pa., in the October issue of "The Glower," describes an interesting installation of Nernst lamps in Seattle, Wash. Visitors to the Alaska-Yukon-Pacific Exposition, soon to be held in that city, will find many fine examples of Nernst illumination. There are more than 13,000 glower units in use in Seattle, and new installations are being made every day.

THE COLUMBIA METER COMPANY, Indianapolis, Ind., announces that, owing to the increased demand for Columbia meters, it has been found necessary to seek more commodious quarters, removing its plant to Tenth and Canal streets, where it has excellent facilities to enable all orders to be filled promptly. The company has just issued a new bulletin, which it will send to any address upon request.

THE DAYTON ELECTRICAL MANUFACTURING COMPANY, Dayton, Ohio, sustained a loss of nearly $40,000, largely covered by insurance, when the two upper stories of its factory were burned and its offices drenched with water. Fortunately a large stock of finished material was on hand, stored in a part of the building not affected by the fire, and the company was able to fill orders promptly. An immediate plan of action was formulated as soon as the fire was under control, the offices were moved by the following afternoon and the factory will be working to its full extent within a few days. The company announces that it is in a position to ship anything in its line promptly, and, despite the fire, finds itself in excellent condition.

CONSOLIDATED RAILWAY, LIGHTING AND REFRIGERATING COMPANY stockholders are invited by a committee, consisting of Isaac L. Rice, A. G. Fromuth and J. L. Watson, to participate in the reorganization of that company. Pamphlets containing a copy of the agreement may be obtained on application to the Manhattan Trust Company, No. 20 Wall Street, who will receive deposits until and including December 1. The committee may be addressed at No. 5 Nassau Street, New York.

THE RIDGWAY DYNAMO AND ENGINE COMPANY, Ridgway, N. J., builders of automatic engines and dynamo-electric machinery, announces that its Philadelphia office has been moved from the Girard Building to 1017 Witherspoon Building. The office has been placed under the management of Mr. Robert S. Beecher. The company reports that, with its additional lines of side-crank engines and the rapidly improving business conditions throughout the country, the prospects are bright for a largely increased volume of orders during the coming season.

THE SCHULTZ BELTING COMPANY, St. Louis, Mo., has sold to the Roswell Electric Light and Power Company 110 feet of thirty-two-inch, three-ply driving belt. The company is also shipping a thirty-five-inch, three-ply belt for a 500-horsepower mine haulage at Johannesburg, South Africa. The Rosario de Santa Equipment Company, of Argentine Republic, has ordered an eighteen-inch double belt, for driving in one of its mills. The company has also made a shipment of 6,500 feet of miscellaneous belting and a large three-ply belt to Moscow, Russia.

THE HORNBERGER TRANSFORMER COMPANY, Lafayette, Ind., has been incorporated recently, and is composed of local business men. The company has leased, and is negotiating for, the purchase of a factory building located at Fifteenth and Elizabeth streets. All of the accounts receivable of the Lafayette Electrical Manufacturing Company have been purchased, and the manufacture of Hornberger transformers will be continued under the management of William H. Hornberger. Mr. Hornberger has been ill for about a year, but now is almost fully recovered. The company believes that the excellent record established for this well-known make of transformers will be fully maintained, and the new factory is being equipped throughout with modern machinery and improved facilities for turning out large quantities of a high-grade product.

LEGAL NOTES.

NEGLIGENCE IN CROSSING CITY RAILWAY TRACK—Whether failure to look and listen before attempting to cross an interurban street-car track laid along the public highway is negligence, is held, in Chicago & Joliet Electric Railway Company vs. Wanic, 230 Ill. 530, 82 N. E. 821, 15 L. R. A. (N. S.) 1167, to be a question for the jury.

CONTRIBUTORY NEGLIGENCE—One engaged in unloading a wagon, with his body in the path of passing street cars, and who for five or ten minutes fails to look or listen for an approaching car, is held, in Volosko vs. Interurban Street Railway Company, 190 N. Y. 206, 82 N. E. 1090, 15 L. R. A. (N. S.) 1117, to be negligent as a matter of law.

COMPANY LIABILITY IN MAINTAINING SERVICE—One who slips and falls upon a street crossing rendered slippery by oil applied by a trolley company to its tracks to facilitate rounding a curve is held, in Slater vs. North Jersey Street Railway Company (N. J. Err. & App.), 69 Atl. 163, 15 L. R. A. (N. S.) 840, to be entitled to recover for injuries received.

FAILURE TO ANNOUNCE LONG-DISTANCE TELEPHONE CALL—The negligent failure of a telephone company to summon an addressee to receive a long-distance message offering employment is held, in McLeod vs. Pacific States Telephone and Telegraph Company (Or.), 94 Pac. 568, 15 L. R. A. (N. S.) 810, to render the company liable for the loss thereby occasioned.

Directory of Electrical and Allied Engineering and Scientific Societies.

(Published in the Second Issue of Each Month.)

AMERICAN ASSOCIATION OF ELECTRIC MOTOR MANUFACTURERS. Secretary, W. H. Tapley, Walker Electric Company, Twenty-third and Noble streets, Philadelphia, Pa. Next meeting, January, 1909.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE. Secretary, L. O. Howard, Cosmos Club, Washington, D. C. Annual meeting, Baltimore, Md., January, 1909.

AMERICAN ELECTROCHEMICAL SOCIETY. Secretary, Dr. J. W. Richards, Bethlehem, Pa.

AMERICAN ELECTROTHERAPEUTIC ASSOCIATION. Secretary, Dr. Albert C. Geyser, 352 Willis Avenue, New York, N. Y.

AMERICAN FOUNDRYMEN'S ASSOCIATION. Secretary Dr. Richard Moldenke, Watchung, N. J.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS. Secretary, Ralph W. Pope, Engineering Societies Building, 29 West Thirty-ninth Street, New York, N. Y.

AMERICAN INSTITUTE OF MINING ENGINEERS. Secretary, Rossiter W. Raymond, 29 West Thirty-ninth Street, New York, N. Y.

AMERICAN MATHEMATICAL SOCIETY. Secretary, F. N. Cole, 50 West 116th Street, New York, N. Y.

AMERICAN RAILWAY MASTER MECHANICS' ASSOCIATION. Secretary, J. W. Taylor, Old Colony Building, Chicago, Ill.

AMERICAN ROENTGEN RAY SOCIETY. Secretary, Dr. G. C. Johnson, 514 Bijou Building, Pittsburg, Pa. Annual meeting, New York, N. Y., December 28-30.

AMERICAN SOCIETY FOR TESTING MATERIALS. Secretary, Prof. Edgar Marburg, University of Pennsylvania, Philadelphia, Pa.

AMERICAN SOCIETY OF CIVIL ENGINEERS. Secretary, Charles Warren Hunt, 220 West Forty-seventh Street, New York, N. Y.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Secretary, Calvin W. Rice, 29 West Thirty-ninth Street, New York, N. Y. Annual meeting, New York city, December 1-4.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS. Secretary, A. P. Folwell, 239 West Thirty-ninth Street, New York, N. Y.

AMERICAN STREET AND INTERURBAN RAILWAY ASSOCIATION. Secretary, B. V. Swenson, Engineering Societies Building, 29 West Thirty-ninth Street, New York, N. Y.

AMERICAN STREET AND INTERURBAN RAILWAY ACCOUNTANTS' ASSOCIATION. Secretary, H. E. Weeks, secretary and treasurer Tri-City Railway Company, Davenport, Iowa.

AMERICAN STREET AND INTERURBAN RAILWAY CLAIM AGENTS' ASSOCIATION. Secretary, B. B. Davis, claim agent Columbus Railway and Light Company, Columbus, Ohio.

AMERICAN STREET AND INTERURBAN RAILWAY ENGINEERING ASSOCIATION. Secretary, J. W. Corning, electrical engineer Boston Elevated Railway Company, Boston, Mass.

AMERICAN STREET AND INTERURBAN RAILWAY TRANSPORTATION AND TRAFFIC ASSOCIATION.

AMERICAN STREET AND INTERURBAN RAILWAY MANUFACTURERS' ASSOCIATION. Secretary, George B. Keegan, 2321 Park Row Building, New York, N. Y.

ARKANSAS ASSOCIATION OF PUBLIC UTILITY OPERATORS. Secretary, J. E. Cowles, superintendent of lighting Hot Springs Light and Railway Company, Hot Springs, Ark.

ARKANSAS INDEPENDENT TELEPHONE ASSOCIATION. Secretary, Charles F. Speed, Texarkana, Ark.

ASSOCIATION OF CAR-LIGHTING ENGINEERS. Secretary, G. B. Colegrove, Illinois Central Railroad. First annual meeting, Chicago, Ill., November 16.

ASSOCIATION OF EDISON ILLUMINATING COMPANIES. Secretary, D. L. Huntington, second vice-president and manager Washington Water Power Company, Spokane, Wash.

ASSOCIATION OF ELECTRIC LIGHTING ENGINEERS OF NEW ENGLAND. Secretary, Welles E. Holmes, 308 Washington Street, Newton, Mass.

ASSOCIATION OF RAILWAY TELEGRAPH SUPERINTENDENTS. Secretary, P. W. Drew, Wisconsin Central Railway, Milwaukee, Wis.

CALIFORNIA ELECTRIC RAILWAY ASSOCIATION. Secretary, L. E. W. Pioda, Oak and Broderick streets, San Francisco, Cal.

CALIFORNIA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, P. T. Whittier, Spencer, Cal.

CANADIAN ELECTRICAL ASSOCIATION. Secretary, T. S. Young, Toronto, Canada.

CANADIAN STREET RAILWAY ASSOCIATION. Secretary, Acton Burrows, 33 Melinda Street, Toronto, Ontario.

CENTRAL ELECTRIC RAILWAY ASSOCIATION. Secretary, W. F. Milholland, secretary and treasurer Indianapolis Traction and Terminal Company, Indianapolis, Ind.

COLORADO ELECTRIC LIGHT, POWER AND RAILWAY ASSOCIATION. Secretary, J. C. Lawler, Colorado Springs, Colo.

CONNECTICUT STATE STREET RAILWAY ASSOCIATION. Secretary, F. W. Poole, Bridgeport, Conn.

ELECTRIC CLUB OF CLEVELAND. Secretary, George L. Crosby, 1200 Schofield Building, Cleveland, Ohio.

ELECTRICAL CONTRACTORS' ASSOCIATION OF NEW YORK STATE. Secretary, John P. Faure, 7 Water Street, Ossining, N. Y.

ELECTRICAL CONTRACTORS' ASSOCIATION OF STATE OF MISSOURI. Secretary, Charles J. Sutter, 1220 Pine Street, St. Louis, Mo.

ELECTRICAL TRADES ASSOCIATION OF CHICAGO. Secretary, Frederick P. Vose, Marquette Building, Chicago, Ill.

ELECTRICAL TRADES ASSOCIATION OF PHILADELPHIA. Secretary, E. A. Symmes, 810 Drexel Building, Philadelphia, Pa. Meetings, second and fourth Thursdays of each month.

ELECTRICAL TRADES ASSOCIATION OF CANADA, LIMITED. Secretary, William R. Stanley, Royal Insurance Building, Montreal, Canada.

ELECTRICAL TRADES ASSOCIATION OF THE PACIFIC COAST. Secretary, Albert H. Elliott, Claus Spreckels Building, San Francisco, Cal. Monthly meetings, San Francisco, Cal., first Thursday of each month.

ELECTRICAL TRADES SOCIETY OF NEW YORK (Member National Electrical Trades Association). Secretary, Franz Neilson, 80 Wall Street, New York, N. Y. Board of directors meets second Friday of each month.

EMPIRE STATE GAS AND ELECTRIC ASSOCIATION. Secretary, Charles H. B. Chapin, 154 Nassau Street, New York, N. Y.

ENGINEERS' CLUB OF PHILADELPHIA. Secretary, H. G. Perring, 1317 Spruce Street, Philadelphia, Pa.

ENGINE BUILDERS' ASSOCIATION OF THE UNITED STATES. Secretary, J. I. Lyle, 39 Cortlandt Street, New York, N. Y.

ILLINOIS INDEPENDENT TELEPHONE ASSOCIATION. Secretary, C. A. Camp, Henry, Ill.

ILLINOIS STATE ELECTRICAL ASSOCIATION. Secretary, H. E. Chubbuck, La Salle, Ill.

ILLUMINATING ENGINEERING SOCIETY. Secretary, Van Rensselaer Lansingh, Engineering Societies Building, 33 West Thirty-ninth Street, New York, N. Y.

INDEPENDENT TELEPHONE ASSOCIATION OF TEXAS AND LOUISIANA. Secretary, C. A. Shock, Sherman, Tex.

INDIANA ELECTRIC RAILWAY ASSOCIATION. Secretary, P. H. White, Indianapolis, Ind. Monthly meetings, second Tuesday of each month.

INDIANA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, C. S. Norton, Indianapolis, Ind.

INTERNATIONAL ASSOCIATION OF MUNICIPAL ELECTRICIANS. Secretary, Frank P. Foster, Corning, N. Y.

INTERNATIONAL INDEPENDENT TELEPHONE ASSOCIATION. Secretary, J. B. Ward, Grand Rapids, Mich. Secretary's office, Monadnock Building, Chicago, Ill. Annual convention, Chicago, Ill., December 1-3.

IOWA ELECTRICAL ASSOCIATION. Secretary, W. N. Keiser, Des Moines, Iowa.

IOWA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, C. C. Deering, Boone, Iowa.

IOWA STREET AND INTERURBAN RAILWAY ASSOCIATION. Secretary, L. D. Mathes, Dubuque, Iowa.

KANSAS GAS, WATER, ELECTRIC LIGHT AND STREET RAILWAY ASSOCIATION. Secretary, James D. Nicholson, Newton, Kan.

KENTUCKY INDEPENDENT TELEPHONE ASSOCIATION. Secretary, W. G. Turpine, Henderson, Ky.

MAINE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, M. E. Crow, Houlton, Me.

MAINE STREET RAILWAY ASSOCIATION. Secretary, E. A. Newman, 471 Congress Street, Portland, Me.

MASSACHUSETTS STREET RAILWAY ASSOCIATION. Secretary, Charles S. Clark, 70 Kilby Street, Boston, Mass. Meets second Wednesday of each month, except July and August.

MASTER CAR BUILDERS' ASSOCIATION. Secretary, J. W. Taylor, 390 Old Colony Building, Chicago, Ill.

MICHIGAN ELECTRIC ASSOCIATION. Secretary, A. C. Marshall, Port Huron, Mich.

MICHIGAN INDEPENDENT TELEPHONE ASSOCIATION. Secretary, A. A. Burch, Battle Creek, Mich.

MILWAUKEE SOCIETY OF ENGINEERS. Secretary, W. Fay Martin, 456 Broadway, Milwaukee, Wis.

MISSOURI ELECTRIC LIGHT, GAS AND STREET RAILWAY ASSOCIATION. Secretary, Claude L. Clary, Sikeston Electric Light and Power Company, Sikeston, Mo.

MISSOURI INDEPENDENT TELEPHONE ASSOCIATION. Secretary, George W. Schweer, Windsor, Mo.

NATIONAL ARM, PIN AND BRACKET ASSOCIATION. Secretary, J. B. Magers, Madison, Ind.

NATIONAL ELECTRICAL CONTRACTORS' ASSOCIATION OF THE UNITED STATES. Secretary, W. H. Morton, 94 Genesee Street, Utica, N. Y.

NATIONAL ELECTRICAL TRADES ASSOCIATION. Secretary, Frederic P. Vose, 1343 Marquette Building, Chicago, Ill.

NATIONAL ELECTRIC LIGHT ASSOCIATION. Secretary, John F. Gilchrist, Commonwealth Edison Company, Chicago, Ill.

NEBRASKA ELECTRICAL ASSOCIATION. Secretary, William Bradford, Lincoln, Neb.

NEBRASKA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, R. E. Mattison, Lincoln, Neb.

NEW ENGLAND ELECTRICAL TRADES ASSOCIATION. Secretary, Alton F. Tupper, 60 State Street, Boston, Mass.

NEW ENGLAND STREET RAILWAY CLUB. Secretary, John J. Lane, 12 Pearl Street, Boston, Mass. Meetings held on fourth Thursday of each month.

NEW YORK ELECTRICAL SOCIETY. Secretary, G. H. Guy, Engineering Societies Building, 29 West Thirty-ninth Street, New York, N. Y.

NEW YORK STATE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, R. Max Eaton, Niagara Falls, N. Y.

NORTHWEST ELECTRIC LIGHT AND POWER ASSOCIATION. Temporary secretary, J. D. Crary, Aberdeen, Wash.

NORTHWESTERN ELECTRICAL ASSOCIATION. Secretary, R. N. Kimball, Kenosha, Wis. Annual meeting, Milwaukee, Wis., January, 1909.

OHIO ELECTRIC LIGHT ASSOCIATION. Secretary, D. L. Gaskill, Greenville, Ohio.

OHIO INDEPENDENT TELEPHONE ASSOCIATION. Secretary, O. O. Welsheimer, Columbus, Ohio.

OHIO SOCIETY OF MECHANICAL, ELECTRICAL AND STEAM ENGINEERS. Secretary, F. W. Ballard, Cleveland, Ohio.

OHIO STREET RAILWAY ASSOCIATION. Secretary, Charles Currie, Akron, Ohio.

OKLAHOMA ELECTRIC LIGHT, RAILWAY AND GAS ASSOCIATION. Secretary, Galen Crow, Guthrie, Okla.

OLD TIME TELEGRAPHERS' AND HISTORICAL ASSOCIATION. Secretary, Frank J. Scherrer, New York, N. Y.

ORDER OF THE REJUVENATED SONS OF JOVE. Mercury, C. B. Roulet, Dallas, Tex.

PACIFIC COAST ELECTRIC TRANSMISSION ASSOCIATION. Secretary, Samuel G. Reed, Portland, Ore.

PENNSYLVANIA ELECTRIC ASSOCIATION. Secretary, E. S. Smith, Towanda, Pa.

PENNSYLVANIA STATE INDEPENDENT TELEPHONE ASSOCIATION, Secretary, H. E. Bradley, 135 South Second Street, Philadelphia, Pa.

PENNSYLVANIA STATE STREET RAILWAY ASSOCIATION. Secretary, Charles H. Smith, Lebanon, Pa.

PIKE'S PEAK POLYTECHNIC SOCIETY. Secretary, E. A. Sawyer, Colorado Springs, Colo. Meetings, second Saturday of each month.

RAILWAY SIGNAL ASSOCIATION. Secretary, C. C. Rosenberg, Bethlehem, Pa. Next annual meeting, Louisville, Ky., October 12-14, 1909.

SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION. Secretary, Arthur L. Williston, Pratt Institute, Brooklyn, N. Y.

SOUTH DAKOTA INDEPENDENT TELEPHONE ASSOCIATION. Secretary-treasurer, E. R. Buck, Hudson, S. D.

SOUTHWESTERN ELECTRICAL AND GAS ASSOCIATION. Secretary, J. A. Myler, Jr., 608 Juanita Building, Dallas, Tex.

STREET RAILWAY ASSOCIATION OF THE STATE OF NEW YORK. Secretary, J. H. Pardee, J. G. White & Co., New York, N. Y.

TEXAS INDEPENDENT TELEPHONE ASSOCIATION. Secretary, Charles F. Speed, Texarkana, Ark.

UNDERWRITERS' NATIONAL ELECTRIC ASSOCIATION. Secretary Electrical Committee, G. M. Goddard, 55 Kilby Street, Boston, Mass.

VERMONT AND NEW HAMPSHIRE INDEPENDENT TELEPHONE ASSOCIATION. Secretary-treasurer, G. W. Buzzell, St. Johnsbury, Vt.

VERMONT ELECTRICAL ASSOCIATION. Secretary, C. C. Wells, Middlebury Electric Light Company, Middlebury, Vt.

VIRGINIA STATE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, B. L. Fisher, Rocky Mount, Va.

WESTERN ASSOCIATION OF ELECTRICAL INSPECTORS. Secretary, W. S. Boyd, 382 Ohio Street, Chicago, Ill.

WESTERN SOCIETY OF ENGINEERS (Electrical Section). Secretary, J. H. Warder, 1737 Monadnock Block, Chicago, Ill.

WISCONSIN ELECTRIC AND INTERURBAN RAILWAY ASSOCIATION. Secretary, Clement C. Smith, president Columbia Construction Company, Milwaukee, Wis.

WISCONSIN INDEPENDENT TELEPHONE ASSOCIATION. Secretary, J. C. Crowley, Jr., Superior, Wis.

ALABAMA LIGHTING AND TRACTION ASSOCIATION. Temporary secretary, F. K. Jackson, Mobile, Ala.

DATES AHEAD.

Association of Car-Lighting Engineers. First annual meeting, Chicago, Ill., November 16.

National Society for the Promotion of Industrial Education. Annual meeting, Atlanta, Ga., November 19-21.

International Independent Telephone Association. Annual convention, Chicago, Ill., December 1-3.

American Society of Mechanical Engineers. Annual meeting, New York city, December 1-4.

American Roentgen Ray Society. Annual meeting, New York city, December 28-30.

Chicago Electrical Show. Coliseum, Chicago, Ill., January 16-30, 1909.

American Association for the Advancement of Science. Annual meeting, Baltimore, Md., January, 1909.

Northwestern Electrical Association. Annual meeting, Milwaukee, Wis., January, 1909.

RECORD OF ELECTRICAL PATENTS.

Issued (United States Patent Office) November 3, 1908.

902,553. RAILWAY-SIGNALING APPARATUS. Edward R. Brodton, Mobile, Ala., assignor to George H. Fonde and Ernest E. Wagar, Mobile, Ala. Filed November 19, 1907. A wireless-telegraph railway-signal system.

902,554. INDICATOR. George Brown, Sarnia, Ontario, Canada, assignor to Brown Automatic Indicator Company, Port Huron, Mich. Filed May 18, 1907. A controller has a co-operating and a selected contact, and means operating upon an over-movement for reversing a motor and for cutting it out again before the co-operating contact is returned to the selected contact.

902,569. DETECTOR. Cornelius D. Ehret, Ardmore, Pa., assignor to International Telegraph Construction Company. Filed July 29, 1905. A wave-responsive device for a wireless signaling system consists of a two-fluid primary cell.

902,588. ROTOR CONSTRUCTION. Charles E. Lord, Norwood, Ohio, assignor to the Bullock Electric Manufacturing Company. Filed June 22, 1905. A revolving field has wedge-shaped field coils whose sides are radial with respect to the shaft.

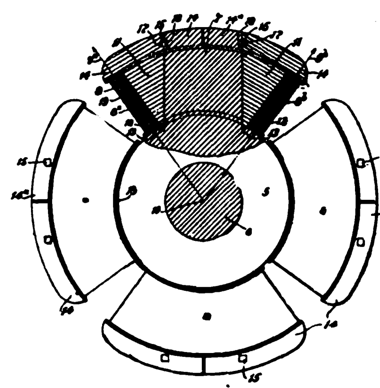
902,600. VALVE-CONTROLLING APPARATUS. William B. D. Penniman, Baltimore, Md. Filed June 23, 1905. An electric motor operates the valve mechanism in both directions and an automatic switch controls the direction of the current through the motor.

902,607. METHOD FOR PRODUCING NITRIC OXIDE. Isaiah L. Roberts, New York, N. Y. Filed February 20, 1907. The method consists in subjecting a mixture of nitrogen and oxygen to an electric arc containing chromium.

902,613. RECEIVING APPARATUS. Harry Shoemaker, Jersey City, N. J., assignor to International Telegraph Construction Company. Filed January 20, 1906. In a wireless signaling system a wave detector consists of a pair of primary cells of minute power connected in opposition to each other.

902,621. MOTOR-CONTROL SYSTEM. Emmett W. Stull, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Filed August 27, 1906. A controller for commutating-pole motors is arranged to connect resistances in series with the motors or in shunt with their field magnets.

902,624. ELECTROMAGNET. Burton W. Sweet, Cleveland, Ohio, assignor to Century Telephone Construction Company, Buffalo, N. Y. Filed May 19, 1906. A telephone drop magnet with self-restoring jack.



902,588.—ROTOR CONSTRUCTION.

902,628. TROLLEY WHEEL. Lewis J. Tetlow, Chicopee Falls, Mass., assignor to New England Trolley Wheel Company, Holyoke, Mass. Filed January 2, 1908. The hub of the wheel has a chamber containing bearing discs and lubricating material forming the spaces between the discs.

902,630. ELECTRIC SIGNALING APPARATUS. Nelson M. Watson, Detroit, Mich., assignor to John Henry Carstens, Detroit, Mich. Filed May 21, 1906. In combination with the throttle and reversing levers of an engine is a battery circuit, including an alarm and a number of indicating signals.

902,637. FLUID-PRESSURE SYSTEM. Bert Aikman, Chicago, Ill., assignor to National Brake and Electric Company, Milwaukee, Wis. Filed May 27, 1907. The pressure in a motor-driven compressed-air system regulates the speed of the motor.

902,641. TELEPHONE SUBSTATION SET. Jules A. Birsfield, Chicago, Ill., assignor to Alfred Stromberg, Chicago, Ill. Filed November 20, 1906. Attached to the inner surface of the door is a sheet of metal upon which are formed projections to serve as one element of a hinge, as lugs for retaining a condenser, and as lugs for mounting a spring latch for holding the door closed.

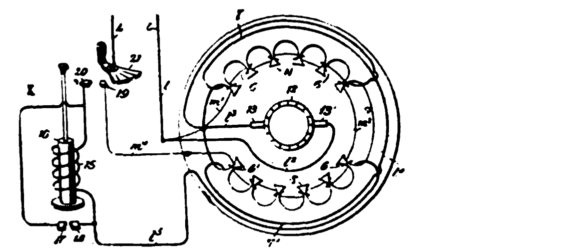
902,642. TRANSMITTER HINGE. Jules A. Birfield, Chicago, Ill., assignor to Alfred Stromberg, Chicago, Ill. Filed March 28, 1907. A ball-and-socket hinge for adjusting the transmitter.

902,681. STORAGE BATERY. David P. Berry, Chicago, Ill., assignor to William Morrison, Chicago, Ill., and M. A. Lumbard, Des Moines, Iowa. Filed January 2, 1904. Renewed March 18, 1908. The battery comprises an upright copper cell, an alkaline electrolyte, a vertical negative element surrounded by a positive element made of concentric cylinders of copper-wire gauze with an interposed layer of prepared copper and cadmium oxide.

902,715. TELEPHONE-EXCHANGE SYSTEM. Elmer R. Corwin, Chicago, Ill., assignor to Monarch Telephone Manufacturing Company. Filed December 12, 1904. Circuits for the supervisory relay and lamps are described.

902,720. SINGLE-PHASE COMMUTATOR MOTOR. George W. Euker, Boston, Mass., assignor to Diehl Manufacturing Company. Filed August 20, 1907. A field magnet having a pair of consequent poles, each of which is symmetrically subdivided, has series windings for each pole and separate serially-connected windings for each of the subdivisions.

902,741. WARP STOP-MOTION FOR LOOMS. Frederic E. Kip, Montclair, N. J. Filed July 27, 1907. A closing drop for an electrical stop-motion.

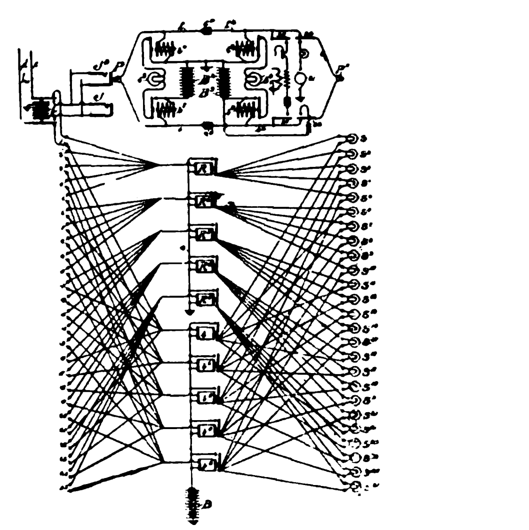


902,720.—SINGLE-PHASE COMMUTATOR MOTOR.

902,753. BULLET PROBE. George E. Marshall, Aguilar, Colo. Filed May 8, 1907. A flexible insulated tube has two complemental probe members at one end adapted to form electrodes, and a low-voltage incandescent lamp in series with a battery.

902,755. ELECTROLYTE FOR ELECTROPLATING. Otto Meyer, Richmond, Va. Filed March 22, 1907. A solution of chloride of copper and chlorides of other metals in alcohol.

902,773. MAGNET FOR TELEGRAPHONES. Harve R. Stuart, Wheeling, W. Va. Filed March 2, 1908. A recording magnet in the form of a solenoid with a recording wire passing axially through the same.



902,930.—TELEPHONE SYSTEM.

902,777. SYSTEM OF ELECTRICAL DISTRIBUTION. Joseph H. Tracy, Philadelphia, Pa. Filed March 19, 1908. Combined with a storage battery is a booster with special windings for regulating the charge and discharge of the battery with fluctuations in the combined alternating and direct-current excitation.

902,781. BALL-BEARING TROLLEY WHEEL AND HARP. Stephen Tully, Jr., Philadelphia, Pa. Filed February 27, 1908. The wheel has a spherical central portion provided with unbroken, smooth, outer bearing surfaces.

902,782 and 902,783. IGNITION SYSTEM FOR EXPLOSION ENGINES. Richard Varley, Englewood, N. J., assignor to the Autocoil Company. Filed October 1, 1906. A cam and vibrator mechanism for opening and closing the primary circuit.

902,792. TYPE-PRINTING TELEGRAPH APPARATUS. Gustaf A. M. Agrell, Stockholm, Sweden. Filed January 8, 1908. An electric type-printing apparatus has a movable type wheel and a number of wheel-operating members.

902,798. INTERMITTENT ILLUMINATING SYSTEM. Francis B. Badt, Chicago, Ill. Filed August 9, 1905. A flasher operated by a solenoid and thermostat.

902,834. CONTROLLER. William D. Pomeroy, Norwood, Ohio, and Edwin C. Wright, Newport, Ky., assignors to the Bullock Electric Company. Filed August 4, 1903. Renewed February 21, 1907. Deflectors are arranged between the contacts of the controller cylinder.

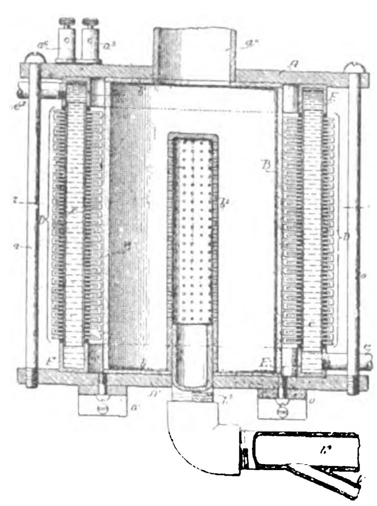
902,851. ELECTRIC-GENERATION SYSTEM. Fred R. Babcock, Chicago, Ill. Filed March 23, 1907. A combination of a generator, storage battery, and regulating devices for charging the battery from a source of power whose speed varies considerably.

902,857. LINT-REMOVER FOR ELECTRICAL WARP STOP-MOTIONS. Edmond Champagne, Jr., Albion, R. I. Filed May 6, 1908. Combined with the contact roll are circuit-closing means and a roll for wiping the contact roll.

902,892. METHOD OF AND APPARATUS FOR ELECTROPLATING. George A. Lutz, Plainfield, N. J., assignor to American Circular Loom Company, Portland, Me. Filed June 27, 1908. The method of plating the interior and exterior of a hollow article consists in simultaneously passing a current through anodes within and without the article and causing the current to flow longer through the outer anode.

902,930. TELEPHONE SYSTEM. Harry G. Webster, Chicago, Ill., assignor to Kellogg Switchboard and Supply Company, Chicago, Ill. Filed December 19, 1902. In connection with a number of telephone lines are line relays, the total number of which is less than the number of lines.

902,936. HEAT-CONTROLLING APPARATUS. Michael J. Brierty, Chicago, Ill. Filed January 20, 1908. An electromagnetically-controlled motor drives a shaft through a train of gears.



903,116.—PYRO-ELECTRIC GENERATOR.

902,960. ELECTRIC-LIGHT FIXTURE. John H. Goehst, Chicago, Ill. Filed February 13, 1908. To the base of the chandelier stem is attached a support through the perforations of which the sockets extend.

902,962. PUSH-BUTTON FOR ELECTRIC SWITCHES. Gilbert W. Goodbridge, Bridgeport, Conn., assignor to the Perkins Electric Switch Manufacturing Company, Bridgeport, Conn. Filed July 24, 1908. A sheet-metal button-head is fastened to a stem having a tubular head.

902,975. STORAGE BATTERY. Simon Lake, Bridgeport, Conn. Filed July 6, 1907. Each battery plate consists of two rectangular grids united at their tops and provided on both sides with a number of recesses containing active material.

902,985. CONTROLLER FOR MOTOR TRACTION CARS. William C. Mayo, El Paso, Tex., assignor to George E. Briggs, Barstow, Tex., and to John Houlehan, El Paso, Tex. Filed February 24, 1908. The movement of the controller arm in one direction governs the electric motors; the movement in the other direction governs the electrically-controlled brakes.

902,990. ARC LAMP. Richard P. Myers, Walthamstow, England. Filed July 22, 1907. In this arc lamp there is a thermally-expansible metal strip arranged in series with the arc.

903,076. AUTOMATIC FIRE-ALARM SYSTEM. Charles J. Fox, London, England. Filed August 3, 1906. A combined service electric-bell system and an automatic fire-alarm system has a service-bell circuit, a thermostat circuit and a corridor-bell circuit.

903,090. DYNAMOMETER FOR EXPLOSION ENGINES. Nevil M. Hopkins, Washington, D. C. Filed February 12, 1908. A fitting on the cylinder carries the gas igniter and a thermocouple, the latter being connected to an external electric indicator.

903,116. PYRO-ELECTRIC GENERATOR. George J. Vokel, Philadelphia, Pa. Filed January 15, 1908. A number of thermoelectric couples are arranged in sets, the inner ends being heated and the middle portions cooled through a set of vertical conduits.

903,130. BINDING POST. Charles Cuno, Meriden, Conn., assignor to Connecticut Auto Engineering Corporation, Meriden, Conn. Original application filed September 19, 1906. Divided and this application filed November 11, 1907. A threaded binding post with washer and nut.

903,141. SOCKET FOR INCANDESCENT ELECTRIC LAMPS. George B. McBean, Chicago, Ill., assignor to Mechanical and Electrical Manufacturing Company, Chicago, Ill. Filed May 18, 1907. An attaching base contains a shell to which is fastened a button provided with a shoulder that interlocks with the corresponding hole in the shell.

903,152. COMBINED FIRE-ALARM AND EXTINGUISHING SYSTEM. Charles E. Buell, North Plainfield, N. J., assignor to General Fire Extinguisher Company, New York, N. Y. Filed May 10, 1900. Combined with a sprinkler system is a telephone circuit and means for sending different signals over this circuit.

903,153. COMBINED TELEPHONE AND FIRE-ALARM SYSTEM. Charles E. Buell, North Plainfield, N. J., assignor to General Fire Extinguisher Company. Originally filed May 10, 1900. Divided and this application filed April 9, 1901. A modification of No. 903,152.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired November 10, 1908:

462,681. ELECTRIC CONDUCTOR. J. A. Barrett, Brooklyn, N. Y.

462,688. ELECTRIC-RAILWAY SYSTEM. H. C. Camp, St. Paul, Minn.

462,696. ICE-CREAM FREEZER. T. B. Garretson and W. E. Thatcher, Oskaloosa, Iowa.

462,698. ELECTRIC ARC LAMP. J. E. Giles, Hazleton, Pa.

462,741. POLICE-SIGNAL TELEGRAPH SYSTEM. C. A. Rolfe, Chicago, Ill.

462,751. ELECTRIC-RAILWAY MOTOR. C. J. Van Depoele, Lynn, Mass.

462,756. CARBON HOLDER FOR ARC LAMPS. J. J. Wood, Brooklyn, N. Y.

462,793. ELECTRIC CAR BRAKE. J. D. Collier and J. P. Miller, Woodville, Tex.

462,794. ELECTRICAL CONNECTION AND SIGNAL FOR RAILWAY CARS. J. D. Collier and J. P. Miller, Woodville, Tex.

462,807. ELECTRIC CAR COUPLING. J. D. Collier and J. K. P. Miller, Woodville, Tex.

462,808. POLICE-SIGNAL SYSTEM. N. B. Cregier, Chicago, Ill.

462,813. SIGNAL SYSTEM FOR TELEPHONE PAY STATIONS. Wm. Gray, Hartford, Conn.

462,835. ELECTRICAL INDICATOR FOR ELEVATORS. C. G. Armstrong, Chicago, Ill.

462,850. ELECTRIC CIRCUIT-CLOSING AND BREAKING DEVICE FOR RAILWAY TRACKS. T. H. Patenall, Rahway, N. J.

462,881. ARMATURE FOR DYNAMO-ELECTRIC GENERATORS. S. H. Short, Cleveland, Ohio.

462,882. ARMATURE FOR DYNAMO-ELECTRIC MACHINES. S. H. Short, Cleveland, Ohio.

462,901. DUPLEX AND QUADRUPLEX TELEGRAPHY. F. W. Jones, New York, N. Y.

462,973. BRUSH HOLDER FOR DYNAMO-ELECTRIC MACHINES. E. Thomson and Wm. O. Wakefield, Lynn, Mass.

463,001. ELECTRICAL ANNUNCIATOR. J. B. Smith, Manchester, N. H.

463,020. ELECTRICAL RAILWAY SYSTEM. G. T. Woods, New York, N. Y.

463,024. REVERSIBLE ELECTRIC TROLLEY. J. W. Bates and C. E. Blake, Minneapolis, Minn.

463,079. ELECTRIC CONDUCTOR. C. T. Snedekor, New York, N. Y.

463,086. ELECTRIC SAFETY CUT-OUT DEVICE. A. G. Waterhouse, Hartford, Conn.

CONTENTS.

CAR-LIGHTING ENGINEERS.

The first annual meeting of the Association of Car Lighting Engineers was held the best part of the week at the Grand Pacific Hotel, Chicago, and several thoroughly interesting and profitable sessions were participated in. On Wednesday evening the annual banquet was held, and on Friday the engineers made a visit of inspection to Milwaukee.

Two of the papers read at the opening session were particularly interesting. The first, by Mr. Patrick Kennedy, referred briefly to the general developments of car lighting by electricity, utilizing both the straight storage-battery equipment and combinations of axle-driven generators and other forms of installation. In the course of his paper Mr. Kennedy called attention to several absurdities upon which patents had been granted, and through which it was expected that the problem would be solved.

The other paper was by Mr. W. L. Bliss, and brought out with great clearness the innumerable difficulties under which the pioneers in this development have labored. Contrary to the present-day spirit of enterprise, there were not many railroad magnates in the old days who would consent to the spending of considerable sums of money for the trying-out of the various systems of car lighting. Mr. Bliss paid tribute, however, to several of those who, through their generosity and broadmindedness, had made possible the present-day developments.

While the advantage of using electric incandescent lamps for car lighting was recognized long ago, and installations made both here and abroad in the early eighties, the general tendency, except on a few of the larger roads, has been to get along in a loose fashion with any light which might be available and easily installed, placing the light units in a more or less haphazard fashion. The car-lighting engineer of today realizes that the comfort of the passenger will be greatly increased, and the value of the services of the engineers to their employers enhanced, if proper consideration is given to selecting the best types of equipment, as regards utility, reliability and accessibility, and distributing the light sources in the most scientific fashion.

Car-lighting engineering involves considerable detail of electrical ingenuity in construction and design, high mechanical ability in the same directions, and talent in the selection and placement of the lighting units. Today we call the latter feature illuminating engineering. So there is a possibility of combining the services of highly-trained men to work out the best system of power generation, and the best system of light distribution.

The electric train-lighting system today consists essentially of a dynamo either driven from the axle of the train by some form of transmission, or operated by an auxiliary prime mover supplied with steam from the locomotive, a storage battery, a pole-changing device for taking care of the direction of running, an automatic switching contrivance for effecting the control of the battery, lamp and dynamo connections, and a regulating device for taking care of generator and lamp regulation.

The difficulties involved in axle-lighting in securing a direct and continuous drive have been almost insuperable. In most cases it is necessary to take the rough axle as it is received, equip it with a collar or hollow sleeve, and provide some form of elastic or telescopic transmission gearing between the driving axle and the pulley of the generator. The pounding and hammering to which the generator and the driving system are subjected make direct gearing almost impossible, and to secure a proper method of suspension the greatest effort has been made. The problem seems to have been best solved by the use of the rubber belt with a sufficiently large pulley ratio and wide enough pulley faces. Where the equipments are large enough to be built ruggedly and made a part of the locomotive, the problem of direct gearing is simplified. In the other case the belt forms a sort of mechanical safety fuse in the power-transmission system.

The equipment of railroad car-repair shops becomes a matter of importance in considering an axle-driven electric-lighting installation. Locomotive roundhouses are equipped with pits, which make the inspection of heavy generator cases an easy matter. Where the equipment which forms a part of the car is not placed in an easily accessible position, the labor of the repair man and the car-lighting engineer is greatly increased.

Pole-changers of every description, utilizing air, gas, gravity, mechanical movements, and others electrically operated, have been put forward for use in car lighting. The opinion seems today to favor the electrically-controlled pole-changer and brush-shifting mechanism. Some of the greatest difficulties encountered have been in effecting a proper relation between the dynamo and the discharged storage battery. To secure that regulation which will keep the battery properly charged and connect the dynamo while the train is running to either the lamp circuit or the battery circuit, as conditions may require, and which will automatically switch the battery onto the lamp circuit without prohibitive voltage fluctuations at the lamp terminals when the train is either running slow or standing still, has not been an easy task.

It is the opinion of Mr. Bliss that a great many of these problems have been, or are about to be, solved. The experience gained these many years has been profitably taken advantage of, and the men who have done the work are still available, so that it is easy to believe that they will see the consummation of their labors and enjoy the appreciation of perfected systems of train lighting in the very near future. To this end the association just organized can lend great help, and this is one of the fundamentals of the organization—to effect that uniformity of equipment and betterment of service which will put train lighting on the plane that has been reached in the best types of building illumination today.

MAINTAINING THE MAGNETITE ARC SYSTEM.

The extension of the magnetite arc lamps system in central-station street-lighting applications raises a number of special points in design and operation which are as yet not widely appreciated by power-plant attendants. The use of the constant-current transformer in conjunction with the mercury-arc rectifier presents some unusual problems in wiring, and there is here an excellent opportunity to employ the most advanced forms of iron conduit construction in planning the installation. In an ordinary 2,300-volt alternating-current plant both the constant-current transformer and the mercury-arc rectifier must come between the main station bus-bars and the arc-circuit distributing board. The first piece of apparatus obviously transforms constant potential into constant-current energy, while the mercury rectifier wipes out all the pulsations in one direction and delivers a direct current of constant amperage to the arc panels, since the latter is essential to the operation of the magnetite arc lamp under present commercial conditions. In the lay-out of such a system compactness in apparatus arrangement tends to bring the cost of wiring down, and if the equipment is not crowded, economy in first cost will be consistent with operating flexibility and ease of repairs.

In the actual operation of the system it is most important to keep the lines free from grounds, perhaps even more necessary than in the operation of an ordinary direct or alternating-current arc system. The reason for this is that the small current of four amperes used by the magnetite system at the lamps will not burn off incipient crosses as will the larger current of the older service. Hence a cross means that a circuit goes out of commission until it can be located and removed. Another point of importance is to keep the rectifier tubes from flashing. A flash amounts to an open circuit in this case, and produces a corresponding strain on the insulation of the lines and apparatus.

It is desirable to keep a careful record of the hours of service of each tube on a blank designed for the purpose. Each tube should be numbered, and in this way the life can readily be kept up to date. In some cases the tube life is now exceeding from 2,000 to 2,500 hours, which makes the cost very low at an initial investment of about $25 per tube. The ordinary magnetite arc lamp exhibits a high efficiency at the lamp, since four amperes at eighty volts are adequate for the service, but in order to check the performance of the system as a whole a recording wattmeter should be located just beyond the alternating-current bus-bars, where the initial circuits running to the tube transformers are tapped off. Instead of an average of 320 watts per arc, the total input per lamp at the 2,300-volt bus-bar is liable to be from 380 to 390 watts, representing a loss of about seventeen per cent in all the apparatus of the system. Considering the two current transformations this is not by any means a bad showing, and if the condition of the insulation and the flashing of the tubes are kept under close control, the results ought to be satisfactory in cases where this system seems to be the best for the local requirements.

MUNICIPAL LIGHTING IN CHICAGO.

At a recent meeting of the Chicago Electric Club, William Carroll, City Electrician of Chicago, made some interesting comparisons of the lighting of Chicago and other great cities in this country. Early in the year it was discovered that, as compared with New York, which contained 14,756 municipal arc lamps, Chicago had 8,822. The latter city had 3,000 less than Philadelphia, and a great many more than Cincinnati, Boston or St. Louis. The annual cost of municipal lighting in Chicago last year was $1,031,542; in New York, $2,648,546; in Philadelphia, $1,621,049, and in the other cities named considerably less. Only two of the cities—New York and Philadelphia—had a greater estimated candlepower than Chicago, and only one—New York—a greater area to be lighted.

It is interesting to note the development of the cost of municipal lighting. In 1895 it cost Chicago $1,098,000, in round numbers, for an estimated candlepower of 3,964,000. For the year 1907 the cost was $1,031,542, and the estimated candlepower 18,233,000.

Considerable improvement will be effected by changing over from the old steam stations to the new transformer substations, which will receive their primary source of current from the Drainage Canal system. The circuits which, under the old conditions, sometimes contained twenty-eight miles of wire, will also be materially shortened, the substations being established at natural centers of distribution.

It is estimated that in order to properly light the Chicago district at least 29,000 arc lamps will be needed. Assuming a cost of $115 per lamp, the total required would be nearly $2,000,000. Adding to this the cost of replacing the existing equipment, the cost would come to approximately $2,305,000.

Mr. Carroll and his predecessors have done the best possible with the facilities at hand, and the appropriations which have been available for municipal lighting. If there is to be adequate lighting in this great city, and if this result is to be accomplished quickly, the large amount of money necessary must be secured at one time, and can hardly come out of the general taxes. The adequate lighting of the city at the present day will certainly inure to the benefit of posterity, and it does not seem unreasonable that posterity should be saddled with some of the burden, and effectual means taken at once to secure, by bonds or otherwise, the wherewithal to effect this very necessary public improvement.

ELECTRIC HEATING.

The subject of electric heating has come to the fore of late years, and has attracted a good deal of discussion. Through the persistent efforts of a few hardy workers the possibilities of this method have been forced on the central stations and the manufacturers, and today we are more or less familiar with a number of contrivances for utilizing electricity as an agent for producing heat in domestic and industrial operations.

At the meeting of the American Institute of Electrical Engineers last week, Mr. W. S. Hadaway, Jr., presented a paper entitled "Electric Heating," which, in a most conservative fashion, pointed out some of the limitations and advantages of heating by electricity. It appears that for industrial operations where a high heat and localized application are desirable, there is nothing so economical as the electric heating device, leaving out of consideration the concomitant advantages of cleanliness, convenience and better hygienic conditions. In the larger applications, such as heating large rooms, it would appear that electricity is a rather poor competitor of low-pressure steam, especially where steam is readily available. On the other hand, there are those exponents of electric heating for both domestic and industrial applications who do not hesitate to say that the apparatus for converting electrical energy into heat is available, and all that is needed to make it highly popular and strictly essential is a cheapening of the cost of production. In competition with electricity the price of gas has been brought to a pretty low level, and the possibility exists that as competition continues, and as the materials of construction are more conservatively handled and the cost of production is reduced, electricity will become cheaper at a greater rate than gas. The possibility of utilizing large waterpowers, thus securing low power costs, with the probability of the raw material from which gaseous and solid fuel is converted increasing in value, heightens the likelihood of electricity taking first place as a heating agent.

THE ELECTRIFICATION OF THE ST. CLAIR TUNNEL.

On other pages of this issue there appears an illustrated description of the features of the electrification of the tunnel under the St. Clair River, operated by the Grand Trunk system between Port Huron, Mich., and Sarnia, Ontario. From portal to portal the tunnel is 6,032 feet in length, and the electrification has been carried out under the direction of the engineers of the company, with Bion J. Arnold acting in a consulting capacity.

Several interesting features in electrical and mechanical design have been worked out in order to make expedient the handling of trains through this tunnel under rather difficult conditions. As is well known, the electrical system of propulsion is supplied by alternating current at twenty-five cycles and 3,300 volts, the current being stepped down by means of ventilated transformers carried on the locomotives to 235 volts for use by the motors. The power station is built on the Port Huron bank of the St. Clair River, almost directly over the tunnel, and the feeders are led to the tunnel by means of a shaft intake extending vertically from the power house.

One of the striking features in the equipping of the generating system is the installation of an automatic system for controlling combustion, to anticipate the demands for increased power when the trains are running through the tunnels and climbing the steep ascents. By means of under-feed stokers and throttling devices the demand for power is anticipated, and a throttling device on the steam supply to the fan engine increases the boiler capacity automatically. As the pressure reestablishes itself and tends to rise above normal, the supply of steam to the fan engine is diminished, bringing about equilibrium of service.

Final Report International Conference on Electrical Units and Standards.

The sessions of the International Conference on Electrical Units and Standards were concluded on October 22. A progress report of the meetings, and including a preliminary draft of the specifications relating to mercury resistance standards, deposition of silver, and to the Weston normal cell, was given in the ELECTRICAL REVIEW AND WESTERN ELECTRICIAN of November 7. The final report adopted by the Conference is as follows in full:

The Conference on Electrical Units and Standards, for which invitations were issued by the British government, was opened by the president of the Board of Trade, the Right Hon. Winston S. Churchill, M. P., on Monday, October 12, 1908, at Burlington House, London, S. W. Delegates were present from twenty-one countries, and also from the following British dependencies, namely, Australia, Canada, India and the Crown Colonies. It was decided by the conference that a vote each should be allowed to Australia, Canada and India, but a vote was not claimed or allowed to the Crown Colonies. The total number of delegates to the conference was forty-three, and their names are set out in Schedule A appended to this report.

The officers of the conference were: President, the Right Hon. Lord Rayleigh, O. M., president of the Royal Society; vice-presidents, Prof. S. A. Arrhenius, Dr. M. Egoroff, Dr. Viktor Edler von Lang, M. Lippmann, Dr. S. W. Stratton, Dr. E. Warburg; secretaries, Mr. M. J. Collins, Mr. W. Duddell, F. R. S., Mr. C. W. S. Crawley, Mr. F. Smith.

The conference elected a technical committee to draft specifications and to consider any matter which might be referred to the committee and to report to the Conference. The Conference and its technical committee each held five sittings. As a result of its deliberation the Conference adopted the resolutions and specifications attached to this report and set out in Schedule B, and requested the delegates to lay them before their respective governments with a view to obtaining uniformity in the legislation with regard to electrical units and standards.

The Conference recommends the use of the Weston normal cell as a convenient method of measuring both electromotive force and current when set up under the conditions specified in Schedule C.

In cases in which it is not desired to set up the standards provided in the resolutions, Schedule B, the Conference recommends the following as working methods for the realization of the international ohm, the ampere and the volt:

1. For the International Ohm.

The use of copies, constructed of suitable material and of suitable form and verified from time to time, of the international ohm, its multiples and submultiples.

2. For the International Ampere.

(a) The measurement of current by the aid of a current balance standardized by comparison with a silver voltameter;

(b) The use of a Weston normal cell whose electromotive force has been determined in terms of the international ohm and international ampere, and of a resistance of known value in international ohms.

3. For the International Volt.

(a) A comparison with the difference of electrical potential between the ends of a coil of resistance of known value in international ohms, when carrying a current of known value in international amperes; or

(b) The use of a Weston normal cell whose electromotive force has been determined in terms of the international ohm and the international ampere.

The duty of specifying more particularly the conditions under which these methods are to be applied has been assigned to the Permanent Commission, and pending its appointment, to the scientific committee to be nominated by the president (see Schedule D), who will issue a series of notes as appendix to this report.

The Conference has considered the methods that should be recommended to the governments for securing uniform administration in relation to electrical units and standards, and expresses the opinion that the best method of securing uniformity for the future would be by the establishment of an international electrical laboratory with the duties of keeping and maintaining international electrical standards. This laboratory to be equipped entirely independently of any national laboratory.

The Conference further recommends that action be taken in accordance with the scheme set out in Schedule D.

SCHEDULE A—LIST OF COUNTRIES AND DELEGATES.

America (United States).—Dr. S. W. Stratton, Dr. Henry S. Carhart, Dr. E. B. Rosa.

Austria.—Dr. Viktor Edler von Lang; Dr. Ludwig Kusminsky.

Belgium.—Prof. Eric Gérard, M. Clement.

Brazil.—Mr. L. Weiss.

Chile.—Don Victor Eastman.

Colombia.—Don Jorge Roa.

Denmark and Sweden—Prof. S. A. Arrhenius.

Ecuador.—Sr. Don Celso Nevares.

France.—Prof. Lippmann, M. R. Benoit, M. de Nerville.

Germany.—Prof. Warburg, Prof. Jaeger, Prof. Lindeck.

Great Britain.—The Right Hon. Lord Rayleigh (president), Prof. J. J. Thomson, Sir John Gavey, Dr. R. T. Glazebrook, Major W. A. J. O'Meara, Mr. A. P. Trotter.

Guatemala.—Dr. Francisco de Arce.

Hungary.—Joseph Váter, Dr. Desiré Harsanyi.

Italy.—Prof. Antonio Ròiti.

Japan.—Dr. Osuke Asano, Mr. Shigeru Kondo.

Mexico.—Don Alfonso Castelló, Don José Maria Perez.

Netherlands.—Dr. H. Haga.

Paraguay.—M. Maximo Croskey.

Russia.—Dr. N. Egoroff, Col. L. Swentorzetzky.

Spain.—Don José Maria Madariaga, Don A. Montenegro.

Switzerland.—Dr. Fr. Weber, Dr. Pierre Chappuis, Dr. J. Landry.

Australia.—Mr. Cecil W. Darley, Prof. Threlfall.

Canada.—Mr. Ormond Higman.

Crown Colonies.—Major P. Cardew.

India.—Mr. M. G. Simpson.

SCHEDULE B—RESOLUTIONS.

1. The Conference agrees that as heretofore the magnitudes of the fundamental electric units shall be determined on the electromagnetic system of measurement with reference to the centimetre as the unit of length, the gramme as the unit of mass and the second as the unit of time.

These fundamental units are (1) the ohm, the unit of electric resistance which has the value of 1,000,000,000 in terms of the centimetre and second; (2) the ampere, the unit of electric current which has the value of one-tenth (0.1) in terms of the centimetre, gramme and second; (3) the volt, the unit of electromotive force which has the value 100,000,000 in terms of the centimetre, the gramme and the second; (4) the watt, the unit of power which has the value of 10,000,000 in terms of the centimetre, the gramme and the second.

2. As a system of units representing the above and sufficiently near to them to be adopted for the purpose of electrical measurements and as a basis for legislation, the Conference recommends the adoption of the international ohm, the international ampere and the international volt defined according to the following definitions:

3. The ohm is the first primary unit.

4. The international ohm is defined as the resistance of a specified column of mercury.

5. The international ohm is the resistance offered to an unvarying electric current by a column of mercury at the temperature of melting ice, 14.4521 grammes in mass, of a constant cross-sectional area and of a length of 106.300 centimetres.

To determine the resistance of a column of mercury in terms of the international ohm, the procedure to be followed shall be that set out in specification 1 attached to these resolutions.

6. The ampere is the second primary unit.

7. The international ampere is the unvarying electric current which, when passed through a solution of nitrate of silver in water, in accordance with the specification 2 attached to these resolutions, deposits silver at the rate of 0.00111800 of a gramme per second.

8. The international volt is the electrical pressure which, when steadily applied to a conductor whose resistance is one international ohm, will produce a current of one international ampere.

9. The international watt is the energy expended per second by an unvarying electric current of one international ampere under an electric pressure of one international volt.

SPECIFICATION 1.

SPECIFICATION RELATING TO MERCURY STANDARDS OF RESISTANCE.

The glass tubes used for mercury standards of resistance must be made of a glass such that the dimensions may remain as constant as possible. The tubes must be well annealed and straight. The bore must be as nearly as possible uniform and circular, and the area of cross-section of the bore must be approximately one square millimetre. The mercury must have a resistance of approximately one ohm.

Each of the tubes must be accurately calibrated. The correction to be applied to allow for the area of the cross-section of the bore not being exactly the same at all parts of the tube must not exceed five parts in 10,000.

The mercury filling the tube must be considered as bounded by plane surfaces placed in contact with the ends of the tube.

The length of the axis of the tube, the mass of mercury the tube contains, and the electrical resistance of the mercury are to be determined at a temperature as near to 0°C. as possible. The measurements are to be corrected to 0°C.

For the purpose of the electrical measurements, end vessels carrying connections for the current and potential terminals are to be fitted on to the tube. These end vessels are to be spherical in shape (of a diameter of approximately four centimetres), and should have cylindrical pieces attached to make connections with the tubes. The outside edge of each end of the tube is to be coincident with the inner surface of the corresponding spherical end vessel. The leads which make contact with the mercury are to be of thin platinum wire fused into glass. The point of entry of the current lead and the end of the tube are to be at opposite ends of a diameter of the bulb; the potential lead is to be midway between these two points. All the leads must be so thin that no error in the resistance is introduced through conduction of heat to the mercury. The filling of the tube with mercury for the purpose of resistance measurements must be carried out under the same conditions as the filling for the determination of the mass.

The resistance which has to be added to the resistance of the tube to allow for the effect of the end vessels is to be calculated by the formula—

$$A = \frac{0.80}{1{,}063\,\pi}\left(\frac{1}{r_1} + \frac{1}{r_2}\right)\text{ohm},$$

where r_1 and r_2 are the radii in millimetres of the end sections of the bore of the tube.

The mean of the calculated resistances of at least five tubes shall be taken to determine the value of the unit of resistance.

For the purpose of the comparison of resistances with a mercury tube the measurements shall be made with at least three separate fillings of the tube.

SPECIFICATION 2.

SPECIFICATION RELATING TO THE DEPOSITION OF SILVER.

The electrolyte shall consist of a solution of from fifteen to twenty parts by weight of silver nitrate in 100 parts of distilled water. The solution must only be used once, and only for so long that not more than thirty per cent. of the silver in the solution is deposited.

The anode shall be of silver, and the cathode of platinum. The current density at the anode shall not exceed one-fifth ampere per square centimetre and at the cathode one-fiftieth ampere per square centimetre.

Not less than 100 cubic centimetres of electrolyte shall be used in a voltameter.

Care must be taken that no particles which may become mechanically detached from the anode shall reach the cathode.

Before weighing, any traces of solution adhering to the cathode must be removed and the cathode dried.

SCHEDULE C.—WESTON NORMAL CELL.

The Weston normal cell may be conveniently employed as a standard of electric pressure for the measurement both of electromotive force and of current, and when set up in accordance with the following specification may be taken, provisionally,* as having, at a temperature of 20°C., an electromotive force of 1.0184 volts.

SPECIFICATION RELATING TO THE WESTON NORMAL CELL.

The Weston normal cell is a voltaic cell which has a saturated aqueous solution of cadmium sulphate ($CdSO_4$ 8/3 H_2O) as its electrolyte.

The electrolyte must be neutral to Congo red.

The positive electrode is mercury.

The negative electrode of the cell is cadmium amalgam consisting of 12.5 parts by weight of cadmium in 100 parts of amalgam.

The depolarizer, which is placed in contact with the positive electrode, is a paste made by mixing mercurous sulphate with powdered crystals of cadmium sulphate and a saturated aqueous solution of cadmium sulphate.

*See duties of the Scientific Committee, Schedule D.

The different methods of preparing the mercurous sulphate paste are described in the notes.¶ One of the methods there specified must be carried out.

For setting up the cell the H form is the most suitable. The leads passing through the glass to the electrodes must be of platinum wire, which must not be allowed to come into contact with the electrolyte. The amalgam is placed in one limb, the mercury in the other.

The depolarizer is placed above the mercury and a layer of cadmium sulphate crystals is introduced into each limb. The entire cell is filled with a saturated solution of cadmium sulphate and then hermetically sealed.

The following formula is recommended for the electromotive force of the cell in terms of the temperature between the limits 0° C. and 40° C.:

$$E_t = E_{20} - 0.0000406\,(t - 20°) - 0.00000095\,(t - 20°)^2 + 0.00000001\,(t - 20)^3.$$

SCHEDULE D.

1. The Conference recommends that the various Governments interested establish a permanent International Commission for Electrical Standards.

2. Pending the appointment of the Permanent International Commission, the Conference recommends (*) that the president, Lord Rayleigh, nominate for appointment by the Conference a scientific committee of fifteen to advise as to the organization of the Permanent Commission, to formulate a plan for and to direct such work as may be necessary in connection with the maintenance of standards, fixing of values (†), intercomparison of standards and to complete the work of the Conference (‡). Vacancies on the committee to be filled by co-optation.

3. That the laboratories equipped with facilities for precise electrical measurements and investigations should be asked to co-operate with this committee and to carry out, if possible, such work as it may desire.

4. The committee should take the proper steps forthwith for establishing the Permanent Commission, and is empowered to arrange for the meeting of the next Conference on Electrical Units and Standards, and the time and place of such meeting should this action appear to them to be desirable.

5. The committee or the Permanent International Commission shall consider the question of enlarging the functions of the International Conference on Weights and Measures with a view to determining if it is possible or desirable to combine future Conferences on Electrical Units and Standards with the International Conference on Weights and Measures, in place of holding in the future conferences on electrical units and standards. At the same time it is the opinion of the Conference that the Permanent Commission should be retained as a distinct body, which should meet at different places in succession.

¶Notes on methods pursued at various standardizing laboratories will be issued by the Scientific Committee or the Permanent Commission, as an appendix to this report.

*In accordance with the above, Lord Rayleigh has nominated the following committee, which has been approved by the Conference, viz.: Dr. Osuke Asano, M. R. Benoit, Dr. M. N. Egoroff, Prof. Eric Gérard, Dr. R. T. Glazebrook, Dr. H. Haga, Dr. L. Kusminsky, Prof. G. Lippmann, Prof. A. Rôiti, Dr. E. B. Rosa, Dr. S. W. Stratton, Mr. A. P. Trotter, Prof. E. Warburg, Prof. Fr. Weber, Professor Lindeck.

†This will include the reconsideration from time to time of the electromotive force of the Weston normal cell.

‡With this object the committee is authorized to issue as an appendix to the report of the Conference notes detailing the methods which have been adopted in the standardizing laboratories of the various countries to realize the international ohm and the international ampere, and to set up the Weston normal cell.

Annual Report of Cornell University.

In the annual report of Jacob Gould Schurman, president of Cornell University, which was presented to the Board of Trustees on November 7, the following figures were shown:

There were 4,465 students enrolled for the year ended September, 1908. Of these, 3,734 were regularly enrolled students during the academic year from September to June, and the others were attendants at the summer session and the winter school in agriculture. This is an increase of 240 over the enrollment for the preceding year.

The number of members of the instructing staff is given as 548, excluding the members of the staff of the Medical College, in New York. The faculty at Ithaca is made up as follows: Seventy-five professors, sixty-four assistant professors, six lecturers, 122 instructors and 144 assistants.

New courses have been added to the curriculum in the College of Engineering, notably in the field of sanitary engineering. President Schurman points out that there is little necessity for improvement in the field of hydraulics.

Excluding the Medical College in New York city, which is maintained by separate funds, the productive funds of the university amounted, on August 1, 1908, to $8,628,370.31. The inventoried value of the grounds and buildings was given as $4,263,405.07. The income statement shows a total income from all sources of $1,356,498.59, running short of the expense budget by $12,242, as a result of the purchase of campus lands.

New York Rapid Transit Investigation.

J. Edward Simmons, president of the New York Chamber of Commerce, has appointed Eugenius H. Outerbridge, Paul M. Warburg, Howard C. Smith, Clarence H. Kelsey and Marcellus Hartley Dodge as a special committee of five to investigate the conditions now surrounding the question of the construction of further rapid-transit lines in New York city.

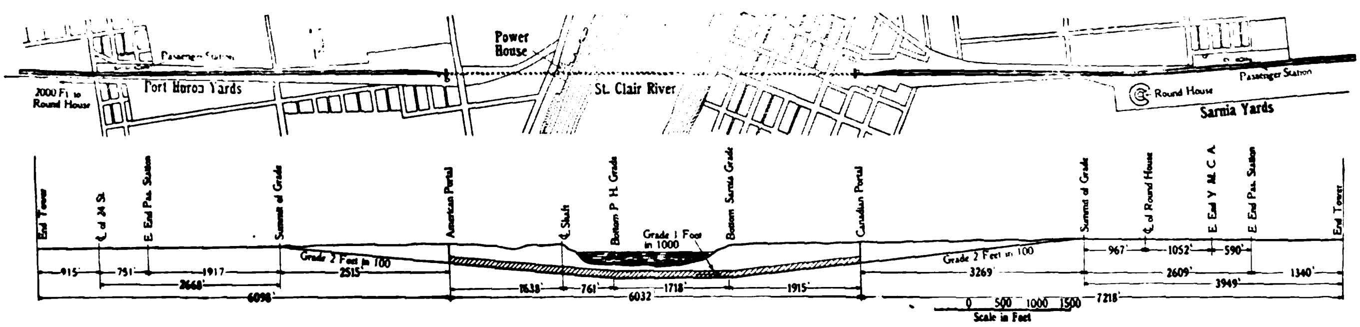
This committee was appointed under a resolution submitted at the last meeting of the Chamber by President Hepburn, of the Chase National Bank. This resolution declared that the present rapid-transit facilities of the city are insufficient and that the construction of additional lines is delayed and obstructed by causes that should be clearly established in order that they may be removed.

The Electrification of the St. Clair Tunnel.

Formal Taking Over by the Grand Trunk on November 12 of Its International Submarine Tunnel between Sarnia, Ont., and Port Huron, Mich.

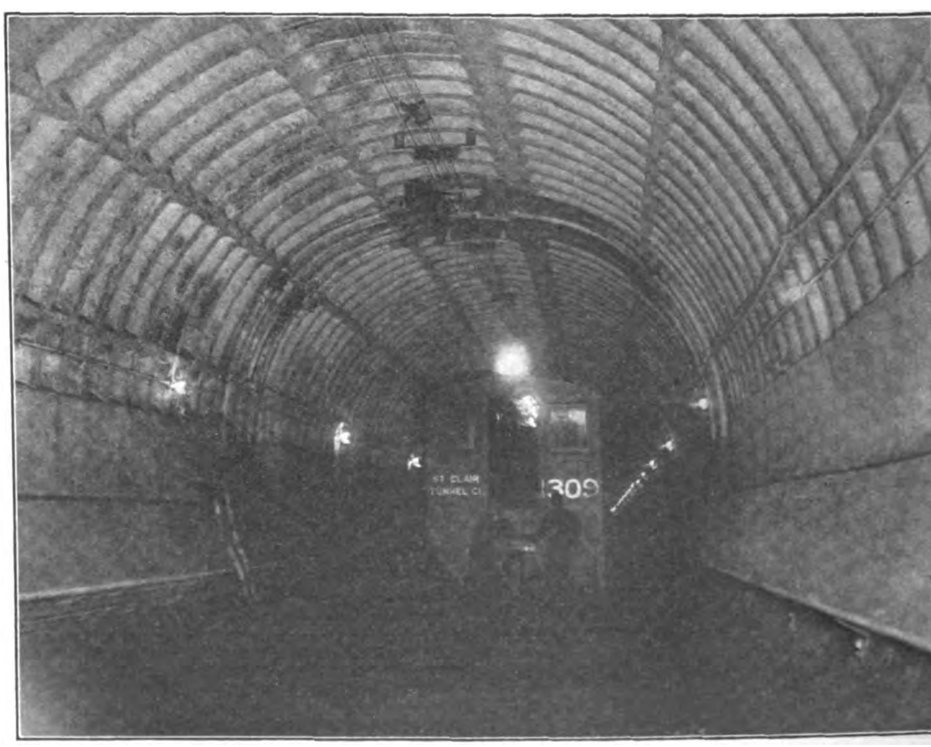
BY O. H. CALDWELL.

The electrification of the St. Clair Tunnel was formally declared complete and its operation by single-phase, alternating-current locomotives taken over by the Grand Trunk Railway on Thursday, November 12, when an inspection party of over one hundred persons, comprising officials of the Grand Trunk and other railroads, engineers, and representatives of the technical and public press, visited the tunnel, pump houses and power plant, and celebrated the electrification event with an international luncheon at Sarnia, tendered by the railroad company. The St. Clair Tunnel under the St. Clair River, near the cities of Port Huron, Mich., and Sarnia, Ontario, linking the 10,000 miles of track of the Grand Trunk system, although finished in 1890 is the longest submarine tunnel in the world. The interest of the formal occasion last week marking the change to an improved motive power was heightened by the presence of the now venerable engineer who carried through the tunnel construction almost a score of years ago, as well as the engineers who have multiplied the capacity of the tunnel and insured the safety and comfort of its passengers.



MAP AND PROFILE OF THE ST. CLAIR TUNNEL AND ADJACENT RAILROAD YARDS.

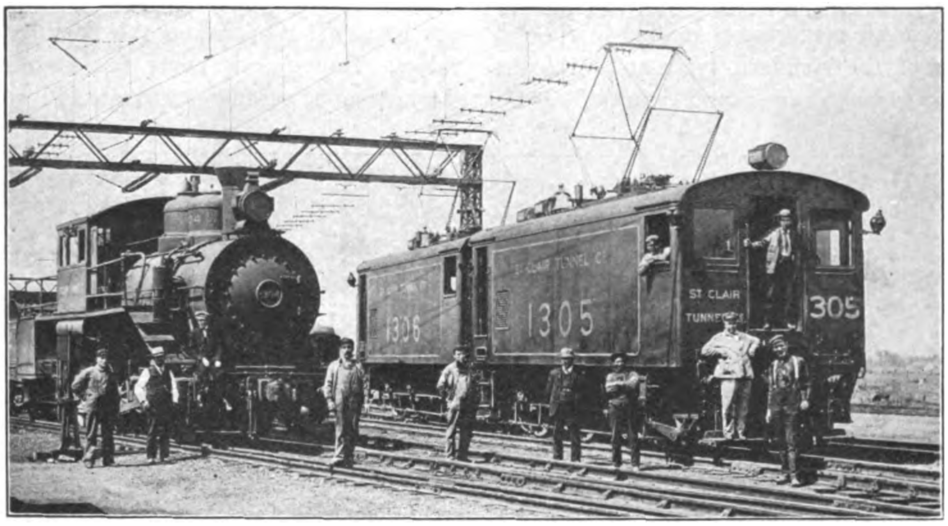
Preliminary work on the St. Clair Tunnel was begun in 1886, and after several unsuccessful efforts the present shield system was finally adopted and the tube was opened for traffic in 1890. From portal to portal the tunnel length is 6,032 feet, the bore being approached by open-cut inclines on the American and Canadian sides of respectively 2,500 and 3,300 feet in length, making the total distance between the American and Canadian summits over two miles. As shown in the accompanying plan and profile, the grade on the approaches and inclined sections of the tunnel is two per cent, while the flat middle section, 1,700 feet in length, has a slight grade toward the Canadian end sufficient to provide for collecting condensation and seepage water. A single track extends through the tunnel, connecting with a double track on both approaches. The tunnel shell proper is nineteen feet in diameter and is made up of sectional cast-iron rings. The total original cost of the tunnel, including machinery and equipment, was $2,700,000.



ELECTRIC LOCOMOTIVE IN THE ST. CLAIR TUNNEL, SHOWING THE INTERSECTION OF THE VERTICAL SHAFT THROUGH WHICH ARE BROUGHT THE FEEDERS FROM THE POWER HOUSE.

The tunnel service is operated by the St. Clair Tunnel Company, a subsidiary of the Grand Trunk Railway system, which takes the trains from the eastern division at the Sarnia yards and delivers them to the western division at the Port Huron yards, and vice versa. For this service four steam locomotives especially designed to exert a large drawbar pull and to burn anthracite coal in order to avoid smoke, were provided to operate the trains over the heavy grades in the tunnel and on the approaches. As the traffic on the road increased, these facilities were found to be inadequate to cope with the car movement, for the maximum weight of the trains handled was limited to about 760 tons, and even with this load the speed on the ascent was often very slow.

The element of danger was always present in the St. Clair Tunnel under steam operation on account of the poisonous gases given out by the locomotives, and several serious accidents occurred before the electrification was made. Under the former conditions it was considered inad-



COMPLETE ELECTRIC LOCOMOTIVE, AND SPECIAL ANTHRACITE-BURNING ENGINE FORMERLY USED TO HAUL TRAINS THROUGH ST. CLAIR TUNNEL.

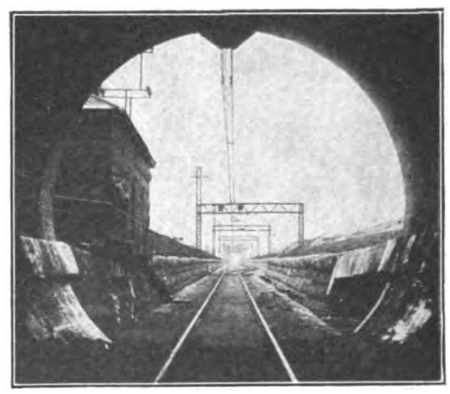
visable to use air brakes on freight trains during the run through the tunnel on account of the danger of the train breaking in two, which would result in setting the air brakes. In such a case before the engine crew could return and make the necessary hose coupling the tunnel would become dangerously filled with gases.

ELECTRICALLY-DRAWN FREIGHT TRAIN EMERGING FROM THE CANADIAN PORTAL. PUMP HOUSE AT RIGHT OF ENTRANCE.

With these serious disadvantages of the existing steam operation in view the Grand Trunk Railway officials took up the consideration of electrifying the St. Clair Tunnel, and Bion J. Arnold was called into conference as consulting electrical engineer. The advantages of the different systems of electrical operation were thoroughly considered and complete estimates were made covering the alternating-current and direct-current systems, the latter both with and without storage batteries. The final decision favored twenty-five-cycle alternating current with a 3,300-volt single-phase supply for the locomotives, using a steam boiler expedient to supply the characteristic of a storage battery in the direct-current system. It is a notable fact that this was the first single-phase installation on so large a scale planned in this country.

According to the specifications required of the contractor the installation must be capable of hauling a 1,000-ton train through the tunnel from terminal to terminal in fifteen minutes at a speed not exceeding a maximum of twenty-five miles per hour, and at not less than a minimum speed of ten miles per hour ascending the grade. The locomotives were specified to be of sufficient capacity to develop a drawbar pull of 50,000 pounds at the operating speed of ten miles per hour. This would permit of the transfer of four trains per hour between Sarnia and Port Huron, which is about three times the capacity at present required by traffic conditions.

The single-phase, twenty-five-cycle alternating-current system for the locomotives has been installed in the yards and through the tunnel. Single-catenary construction is used, the messenger cable of galvanized steel being suspended from insulators on overhead bridges 250 feet apart, and from this cable the working conductor is supported by rods of varying lengths designed to give it a uniform height above the rail of twenty-two feet. In the yards No. 0000 groved copper is used, while on the tunnel approach and in the tunnel are carried two 300,000-circu-

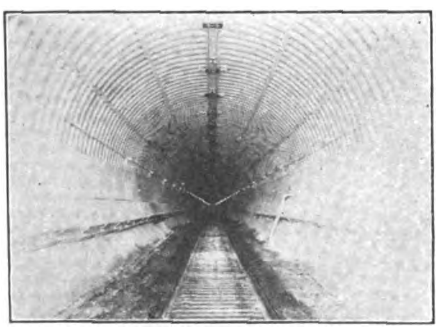


THE APPROACH TO THE AMERICAN SUMMIT AT PORT HURON.

lar-mil conductors. The messenger cables of the outside catenary construction terminates in heavy anchors in the masonry portals, and in the tunnel the working conductor is carried by special brackets, being held nine inches from the tunnel shell. The two messenger cables are supported on barrel-type insulators spaced at 12-foot intervals. The messengers carry special spiders which support the working conductors. These spider supports are not located in the center, but at a point three feet from the middle of the messenger span, as sufficient resiliency of the working conductor is obtained by this construction. The clearance between the messenger cables and the tunnel shell is three inches, and as the trolley wires are suspended six inches below the messengers, the height of the working conductor is fifteen feet five inches above the track rail.

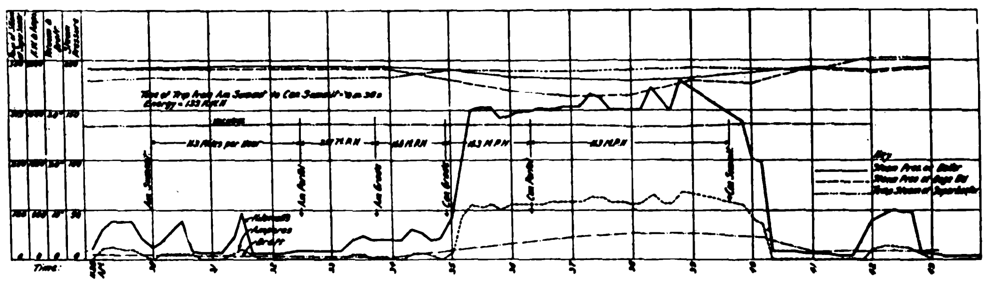
The St. Clair locomotives are of the rigid-frame type, having three pairs of drivers, each axle connected through gears to 250-horsepower, single-phase railway motors. The locomotives weigh sixty-six tons each, and being provided with multiple-unit control, are generally used in pairs. Such a combination of two locomotives was designed to draw a 1,000-ton train through the tunnel and up the two per cent grade, on the latter involving a drawbar pull of 50,000 pounds. The locomotives were further required to start from standstill such a train up the grade and accelerate it to the normal speed of eleven miles per hour. The maximum speed of the locomotives is thirty miles per hour, then exerting a tractive effort of 6,000 pounds.

The trolley-wire pressure of 3,300 volts is stepped down by means of the main transformer, carried on the locomotive, to 235 volts. Control of the motor speed during acceleration and running is effected by bringing out taps from the transformer, thus applying any desired



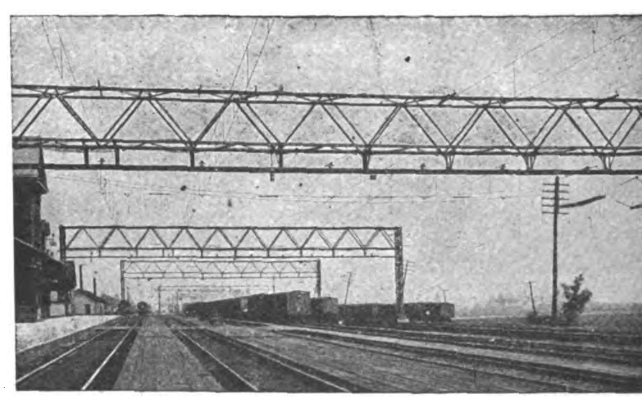
INTERIOR VIEW OF THE ELECTRIFIED ST. CLAIR TUNNEL.

graduated voltage to the motors. The master controller handled by the motorman operates pneumatic valves by means of solenoids deriving current from a twenty-four-volt storage battery. These electro-pneumatic valves in turn control the compressed-air plungers which operate the working contacts. Other operations in the locomotive cab, such as ringing the bell, sanding the tracks, and raising and depressing the pantagraph trolley, are performed pneumatically from push-buttons under the motorman's hand. The main auto-transformer is connected to the trolley through a circuit-breaker provided with a no-voltage release, so that if the car wheels should leave the track, the trolley remaining in contact with the wire, the circuit-breaker automatically opens, thus obviating any possible accident from the trolley voltage charging the ungrounded car. A single-phase motor drives the blower which delivers air to both the transformer and motors, the cooling action being so effective that when operating at full capacity the transformer and motor temperatures are comparatively little above that of the surrounding air. The heated air coming from the transformers may be passed up through the cab for heating purposes, if desired, although other standard electrical heaters are provided. The motor-driven air compressors located in the cab are of the standard type, and, like the blower motor, are supplied by a 100-volt



LOG CURVE OF POWER PLANT OPERATION DURING A TYPICAL RUN THROUGH TUNNEL.

tap from the main transformer. Air from the compressor supplies the straight and automatic air brakes, operates the electro-pneumatic switches and is used for the variety of other minor uses described. Important in operation up the grade in the tunnel and for starting a train of mixed rolling stock, is the gradual acceleration possible with these electric locomotives which are supplied with twenty-one control points, seventeen of which are running positions. A very



OVERHEAD SINGLE-CATENARY 3,300-VOLT TROLLEY CONSTRUCTION IN PORT HURON YARDS.

marked decrease in the number of train breaks-in-two has resulted with the use of these machines.

A half-unit locomotive has been tested with a dynamometer car to show a drawbar pull of 43,000 pounds before slipping the wheels on a sanded track, and on this basis, a drawbar pull of 86,000 pounds might be considered possible with a complete locomotive. The locomotives are operated equally well from either end of the cab, all controlling apparatus being duplicated. Speed indicators mounted in front of the engine-driver's seat show the speed at which the locomotive is running and provide a record for the trip. Other apparatus forming the equipment of each locomotive are the necessary ammeters, voltmeters, wattmeters, preventive resistance coils, circuit-breaker and storage battery for operating the pneumatic valves. Provision is made for charging the battery by means of a small 100-watt motor-generator set. The pantagraph trolley is of the usual standard construction. The bow presses upward on the conductor with a force of from seven to eight pounds. The following general dimensions of a single half-unit are given by the manufacturer:

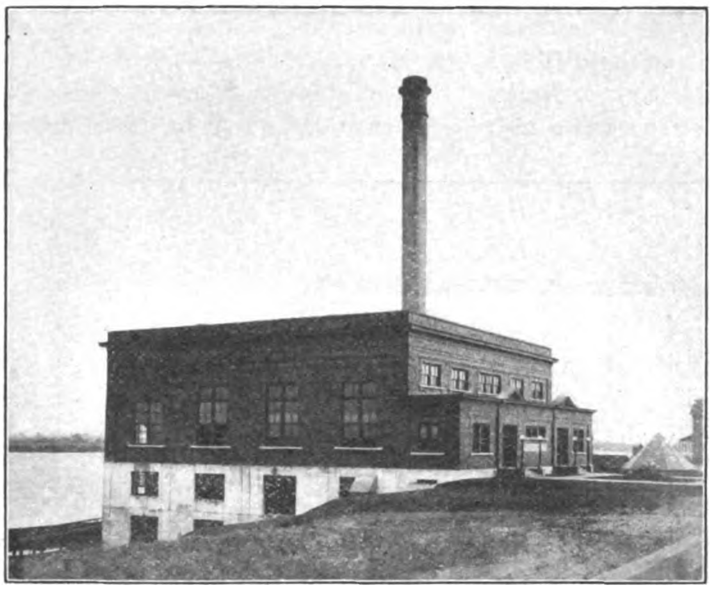
Length over all, 23 feet 6 inches; height from top of rail to top of roof, 13 feet; height from top of rail to top of pantagraph bow when lowered, 14 feet 11 inches; width of cab over all, 9 feet 8 inches; total weight of locomotive half-unit, fully equipped, 67½ tons (this weight is practically evenly divided over three drivers); weight of complete locomotive unit, 135 tons; length of rigid wheel base, 16 feet; diameter of driving wheels, 62 inches.

In service it has been found that the locomotives will readily handle a 1,000-ton train at a speed of even fourteen miles per hour up the two-per-cent grade, and since May 17 of this year the electrical equipment has been in continual service, handling the entire freight and passenger traffic of the St. Clair Tunnel Company, over whose tunnel single track is concentrated, of course, all the business of the Grand Trunk Railway at this point. A log sheet showing train-operation characteristics of a typical run is reproduced on the opposite page.

As the result of the electrification the put. The service provided by the power house involves, besides the propulsion of the trains through the tunnel, the operation of pumps when necessary for clearing the tube of drainage and seepage water, and a small lighting load in the yards, stations and adjacent buildings.

The power plant, shown herewith, is located on the Port Huron bank of the St. Clair River at a point almost directly passing down the walls and leading into the ducts.

The power-house building covers a ground area of 10,000 square feet and is divided longitudinally by a heavy fire-wall which separates the boiler from the turbine rooms. The building is a dignified but ornate structure of steel and brick, and presents an attractive appearance.



THE POWER HOUSE ON THE AMERICAN SHORE. THE CONICAL ROOF CAPPING THE VERTICAL CONDUIT SHAFT IS SEEN AT THE RIGHT.

tunnel is now a clean, white gallery, filled with pure, cool air, and the trip from portal to portal is made in a few minutes without any discomfort to passengers.

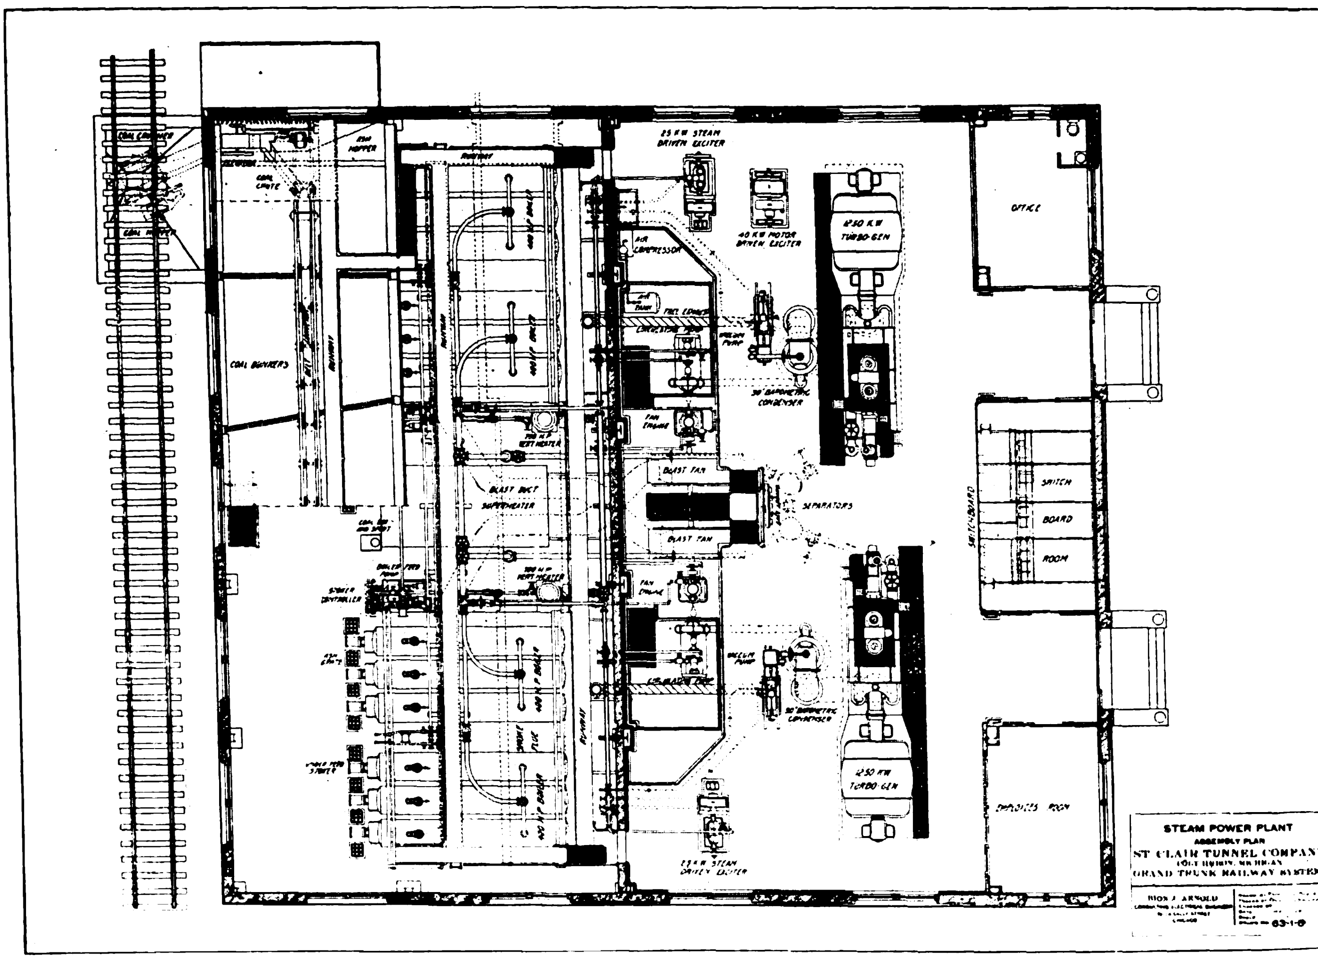
The conditions which have to be met by the power plant are unusual, entailing severe peak-loads during the passage and particularly the ascent of the tunnel trains, with long and irregular intermissions of comparatively small power out- over the tunnel. A vertical shaft extending down to the tunnel which carries the feeders for the trolley, power and lighting circuits, emerges about seventy-five feet from the wall of the building, its upper end being indicated by the pyramidal roof seen in the illustration. The lower end of this shaft is shown in another illustration, where the feeder conduits are seen entering the tunnel tube,

Coal is delivered to the plant over a wooden trestle leading above the receiver hopper which feeds directly into the crusher. The latter has a capacity of about thirty tons per hour, and also acts as a feeder, delivering the coal at a uniform rate to the vertical bucket-elevator extending to the top of the building. From the elevator the coal is dropped onto a conveyor belt, from which it is discharged into the bunkers. A twenty-horsepower, slow-speed induction motor drives the crusher, and a similar ten-horsepower motor operates the elevator and conveyor. The coal bunkers are of reinforced concrete, resting on the structural steelwork of the building, and the space occupied by the buukers, crusher pit and elevator machinery is completely enclosed by a metal partition to obviate the penetration of coal-dust into the boiler room and other parts of the building.

The expedient by which is effected an available reserve of power, amounting in effect to the automatic characteristics of a storage-battery installation, has been worked out with great nicety and ingenuity. By means of the Jones underfeed stoker equipment, the combustion under the furnaces is controlled automatically so as to be proportionate to the draft for power on the station. By means of the regulating mechanism, a part of which is shown near the center of the illustration of the boiler room, both the air supply and the rate of feeding the coal into the boiler furnaces is controlled. This regulation is accomplished by a Skitts regulating valve, which throttles the steam supply to the fan engines, at the same time controlling the rate of stoking through a Cole automatic regulator which is driven from the shaft of the fan engines. Thus when the boiler pressure has re-established itself and tends to rise above normal, the supply of steam to the fan engine is decreased, diminishing the supply of air and the rate of stoking coal to the furnaces.

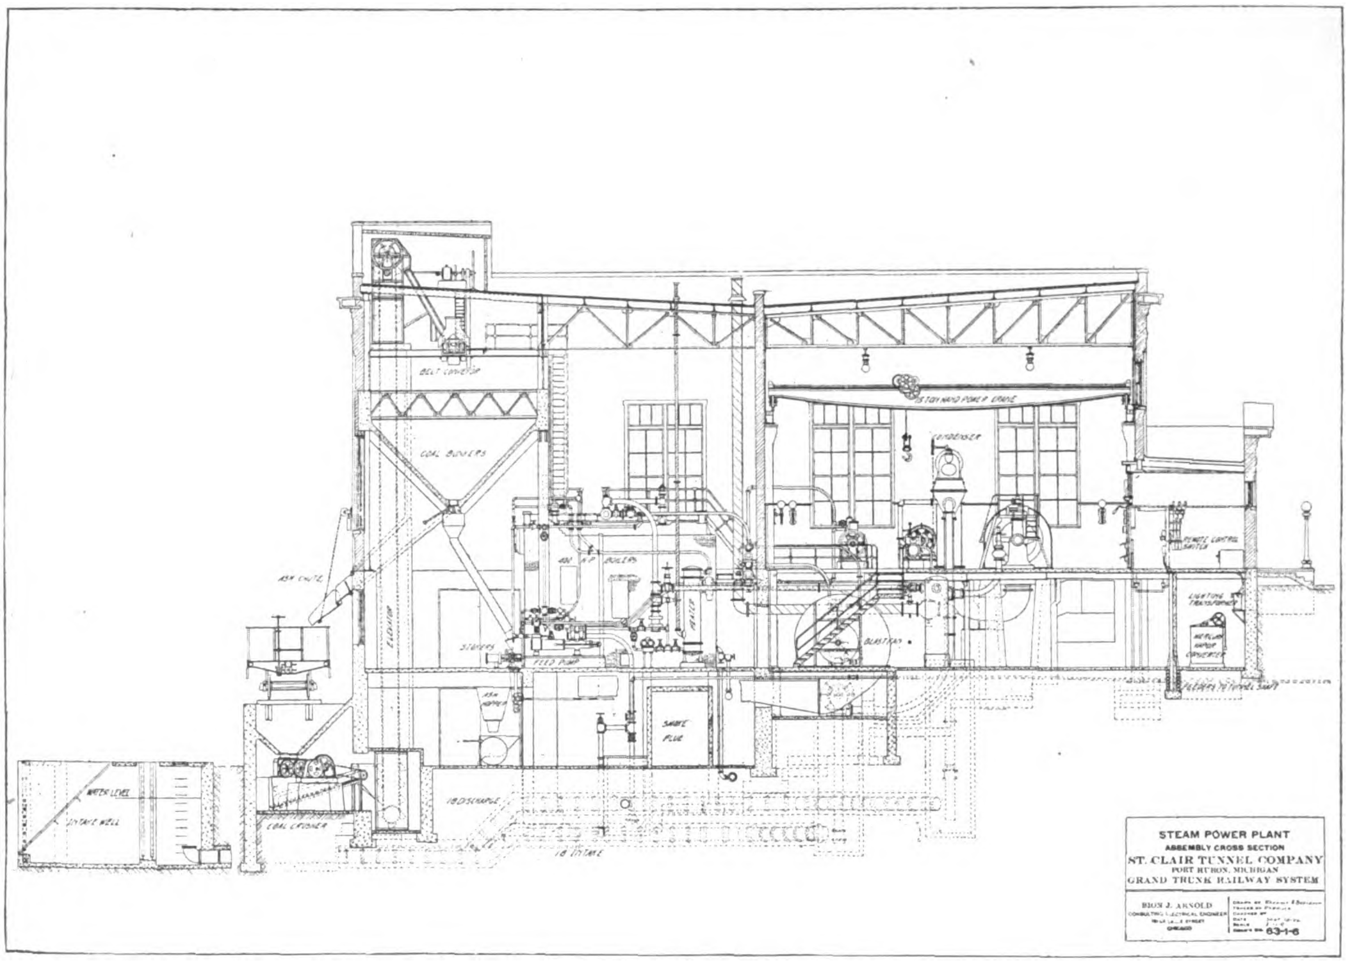
The boiler equipment consists of four 400-horsepower Babcock & Wilcox sectional water-tube boilers arranged in two batteries. These boilers are unusually wide, having the tubes arranged nine high and twenty-one wide, in order to secure quick steaming. Each boiler has three drums forty-two inches in diameter and twenty-three feet four inches in length. The drums thus provide a storage for a large quantity of heated water which becomes available as steam upon a decrease of pressure. The boilers are designed to carry 200 pounds pressure, and are equipped with tandem-connected Morris blow-off valves and the usual pressure and water gauges and check valves. Between the two batteries of boilers is seen the separately-fired Foster superheater, which was furnished by the Power Specialty Company. This superheater has a capacity to add 200 degrees superheat to 36,000 pounds of steam per hour. The superheater is hand-fired, but has an automatic temperature regulator for admitting air either above or below the fires, thus controlling the superheat within thirty degrees. A thermal coupling placed in the superheater steam outlet operates through a relay and solenoid, on the valve of a hydraulic cylinder, which controls the dampers in the air supply.

The alternating-current generating equipment consists of two Westinghouse-Parsons turbo-generators operating at 1,500 revolutions per minute. These develop a voltage of 3,300 volts with a frequency of twenty-five cycles per second. As the principal load on the station is that imposed by the single-phase locomotive demand, these three-phase machines were specified to furnish their full rated load of 1,250-kilowatt, single-phase current. The turbines are, roughly, thirty-seven feet over all, eight feet high and six feet wide. The generators are air-cooled by a self-induced draft provided by vanes on the rotor. Each turbine exhausts into a barometric jet-condenser



PLAN VIEW OF THE STEAM POWER PLANT FOR THE ST. CLAIR TUNNEL ELECTRIFICATION.

with a thirty-inch inlet, manufactured by the H. L. Worthington Company. An automatic release valve may be connected to the free exhaust piping. Condenser cooling water, obtained from the St. Clair River through a concrete and tile intake, is circulated by a ten-inch volute pump driven by seven by nine-inch vertical engines. Rotative straight-line vacuum pumps are supplied with each condensing equipment. Two twenty-five-kilowatt steam-driven exciters are provided, either one of which is sufficient to furnish excitation for a single turbine unit. A motor-driven exciter of forty kilowatts tor-driven exciter; a panel controlling current supply for light and power within the plant, two turbo-generator controlling panels; the locomotive feeder panel; one for the pumping feeders; one for the power and light feeders, and one for the control of the arc-light circuits. No high-tension current is brought to the switchboard itself, all of the high-voltage oil switches being mounted on steel framework in the switch room behind the board. Direct current at 125 volts, supplying excitation, is controlled directly from the main switchboard. The 110-volt lighting current for the power plant wattmeters. Recording wattmeters are arranged to measure the output of the plant required for the various kinds of service furnished. From the operating engineer's station in front of the switchboard, all of the electrical instruments and switches are accessible, while across the turbine-room floor is a gauge-board reporting the complete operation of the boiler plant. A fifteen-ton hand-power traveling crane, manufactured by the Northern Engineering Works, is installed on overhead tracks in the turbine room, and may be used to handle any piece of apparatus in the station.



CROSS SECTIONAL ELEVATION OF THE STEAM POWER PLANT FOR THE ST. CLAIR TUNNEL ELECTRIFICATION.

capacity is ordinarily used in the operation of the plant. A three-phase, 3,300-volt induction motor of the squirrel-cage type drives this machine. All of the excitation apparatus—engines, motors and generators—is of Westinghouse manufacture.

The switchboard, which is mounted on the turbine-room-floor level, contains ten panels, arranged in order from the left as follows: On the first panel is mounted a Tirrill regulator, voltmeters, a frequency meter and synchroscope; the second panel controls the steam-driven exciters; next, a panel controlling the motor-driven exciter; is stepped down by transformers from the 3,300-volt generator buses, or by means of a throw-over switch, can be derived from the exciter bus-bars. The entire lighting load, it should be noted, is carried on the locomotive phase. A close regulation of this voltage is secured by means of the Tirrill regulator, which operates so effectively that only an instantaneous diminution of the luminosity of the lamps is apparent during heavy acceleration of the locomotives.

The switchboard panels in general are provided with the usual apparatus, such as ammeters, voltmeters, and indicating

It is evident that of equal importance with the propulsion of the locomotives through the tunnel, is the reliable maintenance of the tube free from water, since in the case of the tunnel becoming flooded, either from seepage or drainage of rain water, the operation of trains would necessarily be suspended. The Port Huron approach to the tunnel has an area of eleven acres, while the Sarnia approach has an area of thirteen acres. Waste ditches are provided at the side, arranged with retaining levees, constructed to impound a large portion of the water falling on the approaches.

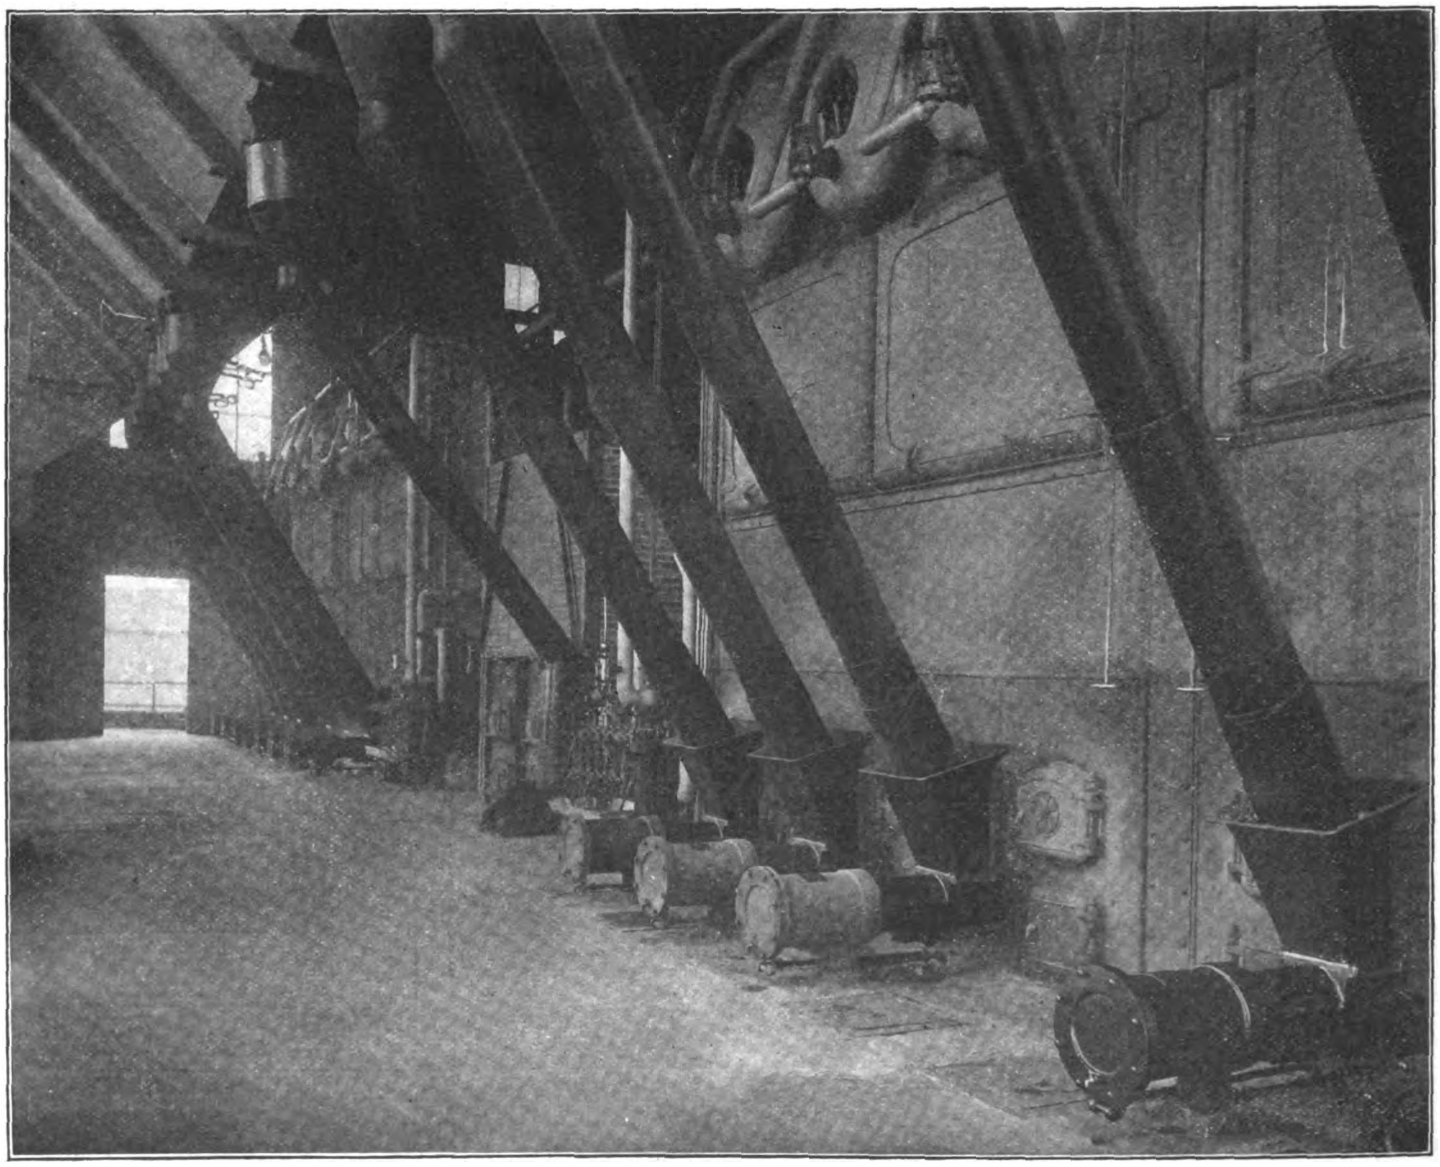
Before the electrification, boiler plants were provided at each portal for the operation of drainage pumps, and in order to take care of any rainfall which might occur it was necessary to keep fires under the boilers and maintain attendants at the pump houses at all hours for a large proportion of the year.

From the Port Huron generating plant three-phase power leads are led down the vertical shaft to the tunnel, and carried in both directions through the tunnels, in paper-insulated, lead-covered cables in ducts at either side of the tube. Emerging from the tunnel portals, the conduits enter the adjacent pump houses supplying three-phase, twenty-five-cycle, 3,300-volt induction motors driving centrifugal pumps. At the Port Huron entrance are two such pumps, each capable of delivering 4,000 gallons per minute, driven by 100-horsepower motors; while at the Sarnia entrance are two 5,500-gallon pumps driven by 200-horsepower motors.

At each pump house there is an additional 150-gallon pump driven by a small induction motor, to rid the wells of the small amount of seepage water that is continually percolating into the tunnel. These pumps need be operated for only a few hours daily. The pump-motor busbars may be supplied from two independent feeders from the power plant. The motor control is effected by means of oil switches on individual panels. As noted before, the flat portion of the tunnel has a slight grade (one-tenth per cent) in the direction of the Sarnia end. In order to dispose of the slight flow of seepage water, at the junction of the Sarnia grade and the flat section—the lowest point in the tunnel—two 150-gallon, motor-operated centrifugal pumps are located. These pumps are similar to those at the portal pump house, with the modification of being entirely enclosed and suitable for continuous operation in the tunnel, subject to conditions of moisture and condensation. These pumps discharge into the drainage well, from which the portal pumps lift the water to the outer level.

Since the electrification, the tunnel walls have been whitened and incandescent lamps placed every twelve and one-half feet throughout the tube in a staggered relation on either side, at a height of about ten feet. The tunnel lamps, of which there are 480, are operated four in series from the 440-volt secondaries of lighting transformers placed at intervals in the tunnel. A similar set of transformers furnishes current for the tunnel drainage-pump motors.

From the pump houses at either portal the lighting and power feeders emerge from conduits, and are carried as overhead conductors on the extended masts of one of the overhead-trolley structure standards. Incandescent lamps in the roundhouses, passenger stations and railroad buildings in both Port Huron and



BOILER ROOM OF THE POWER PLANT, SHOWING AUTOMATIC STOKERS AND REGULATOR WHICH MEETS PEAK LOADS AUTOMATICALLY BY ACCELERATING COMBUSTION.

Sarnia, are furnished from these lines by means of suitable transformers, reducing the 3,300-volt line potential to 110 volts. In the yards of the terminals are about thirty arc lamps, used for general illumination. Unidirectional current for these lamps is furnished by means of a mercury-arc rectifier. The total amount of lighting load is less than 100 kilowatts. At the roundhouse at Port Huron and Sarnia are 3,300-volt motors, supplied from the tunnel power plant, but the entire connected motor load does not exceed 100 kilowatts. Thus the power house is called upon to furnish slightly over 200 kilowatts for lighting and power outside the plant.

Since for the operation of the trains steam is always maintained in the boilers, the starting of the motor pumps following a rainstorm is a very simple matter, and does not require, as with the old steam-pump houses, separate fires and steam pressures for a large portion of the year.

The Tunnel division block-signal system extends from the American to the Canadian summit. In addition to telegraph orders, the conductor is handed a staff when the train enters the tunnel division. The switch and signals then remain locked until this staff is placed in the instrument at the other end of the block. It is said that not a single accident has occurred as the result of improper dispatching during the eighteen years' operation of the tunnel. Additional telephone communication is provided between the switch cabins, the power house and the officials' offices at the town stations. Telephone and telegraph cables extend the entire length of the tunnel.

On Thursday, November 12, as the result of invitations issued by the Grand Trunk Railway to more than 100 prominent railway officials and engineers, and representatives of the technical and public press, on the occasion of the official acceptance of the electrification, an inspection trip through the tunnel and power house was made, a feature of which was the congratulatory luncheon at the Hotel Vendome in Sarnia. Six large new flat-cars had been provided with upholstered coach seats and generously decorated with the national colors of Great Britain and the United States. At 1 o'clock these were boarded by the party and, drawn by a pair of electric locomotives, a slow run was made through the tunnel in order to allow the visitors to examine the features of construction. The tunnel walls had been whitened, the air was pure and cool, and the long row of tunnel lights could be seen converging to the point of change in the grade. The tunnel thus presents a marked contrast to the previous conditions, when a quick trip in closed coaches, behind a steam locomotive, was accompanied by great discomfort and indeed an element of danger, from smoke and asphyxiation.

Arriving at the Sarnia station, the party entered a special train of coaches and were taken to the Vendome Hotel, where a completely appointed luncheon was served. With E. H. Fitzhugh, third vice-president of the Grand Trunk Railway system, presiding in the stead of Charles M. Hays, general manager of the system, who was unable to be present, a series of toasts and speeches were given commemorative of the completion of the tunnel. After the assembled guests had responded to the dictates of international courtesy and good feeling with toasts to King Edward and President Roosevelt, whose names were greeted with hearty applause, Mr. Fitzhugh introduced the venerable Joseph Hobson, who was the chief engineer of the St. Clair Tunnel during its construction. Mr. Hobson is now consulting engineer for the Grand Trunk system. Bion J. Arnold of Chicago, consulting engineer for the Grand Trunk during the electrification of the St. Clair Tunnel, was next introduced and gave a short history of the men and installations that have advanced electric railroading. F. A. Sager, assistant engineer for the Arnold Company, proposed a toast to the Westinghouse Electric and Manufacturing Company, which was represented in the response by C. L. Williams. Cy Warman, who is best known as a writer of railroad stories, made a clever speech, and international amenities were further exchanged in speeches by the mayors of Port Huron and Sarnia, who were next called upon. Following the luncheon, the special train was again boarded, the tunnel trip was made, this time in coaches, and the visitors were delivered at the power house on the Port Huron shore. After an hour spent in careful inspection of this architecturally and mechanically beautiful station, during which the visitors admired the excellence of the maintenance and the ingenuity of the automatic boiler-plant devices, the party returned to the cars and was taken to the Port Huron Depot. Here, so far as the formal programme was concerned, the inspection ceremonies ended, but the majority of the engineers and visitors made a merry dinner party, with some postprandial story-telling features at the Hotel Harrington, before taking the evening trains for their destinations, east and west.

The electrification of the St. Clair Tunnel was undertaken by the Westinghouse Electric and Manufacturing Company, which contracted to be responsible for the installation and successful operation of the entire equipment, a condition which it has now satisfied in the fullest degree. Bion J. Arnold of Chicago was the consulting engineer for the railroad company, whose officials, C. M. Hays, second vice-president and general manager, and E. H. Fitzhugh, third vice-president, took a leading part in the move to electrify. The Westinghouse company's representative on the installation was H. L. Kirker.

Progress on the Detroit Tunnels.

The steel twin tubes of the Michigan Central Railroad's tunnel under the Detroit River from Detroit, Mich., to Windsor, Ont., have now been carried to a point more than half way under the river from the American side. Six of the ten great steel sections are already sunk in the channel and a seventh has been delivered at the work and now lies moored to the Detroit shore. The manner of building the tunnels is said to be unique in this kind of construction. The steel sections have their ends boarded and calked to be water-tight and are floated to position by tugs. Valves are then opened and the section is allowed to settle into place in the trench previously dredged in the river bottom. Air tanks carried on the section lighten it while it is being adjusted into position by the aid of tongues and eyes. A water-tight joint is made between the sections by immense rubber gaskets which fit into grooves in the steel end-rings. Accurate alignment of the tunnel sections is secured by sighting through an instrument from shore, the structural steel masts rigidly mounted upon the sections and extending several feet above the surface of the water when sunken. Heavy board forms of rectangular section enclose the tubes before sinking, and the space between the square and circular sections is pumped full of concrete. After placing the tunnel tubes in position the steel and concrete are covered with a layer of clay obtained from the river bottom. The steel tubes are to be given an internal concrete lining. Both of the concrete approaches on the shore ends are nearing completion and will be ready for use by the time the subaqueous tubes are finished. Work has been suspended for the winter on the placing of more sections, since the water has become too cold for the divers, but the time will be profitably spent in pumping the water out of the tunnel already laid and in finishing work on its interior. The contract date for completion is June 1, 1909, but there is little probability that this enormous undertaking can be finished within a number of months of that time.

The electrification of the Detroit tunnel will be carried out by the General Electric Company, which will install a third-rail direct-current system with a storage battery to meet the high peak loads. Power will be purchased from the Detroit Edison Company, whose 25-cycle, 4,400-volt alternating current will be converted by means of two 1,000-kilowatt synchronous motor-generator sets into 650-volt direct current. The pumping and lighting systems will be operated from alternating-current mains. The electrified zone will be 4.6 miles in length, and with the yards will comprise fifteen miles of track. Several of the locomotives for this service have already been completed by the General Electric Company.

Mineral Products of the Last Ten Years.

The United States Geological Survey, under the direction of George Otis Smith, has prepared a comprehensive table giving the amount and market value of the mineral products of the United States for the years 1898 to 1907, inclusive. Returns are given for sixty-seven products classified into metals, fuels, structural materials, abrasive materials, chemical materials, pigments and miscellaneous products. From this table the figures given below are of interest to the electrical arts. The table was prepared by Edward W. Parker, statistician in charge of mineral resources.

New York Public Service Commission Gives Hearing on Proposed Wilgus Freight Subway.

The Public Service Commission held a hearing in New York on November 11 on the proposed Wilgus freight subway, which the Amsterdam Corporation is seeking to build, and which is intended to facilitate the handling of goods between the railroad freight terminals and the points of wholesale distribution.

W. J. Wilgus, speaking for the project, said that less than half of the water front is open to use by foreign and coastwise trade steamship lines. The major part of the rest is used by the railroads, which are constantly asking for more space. Mr. Wilgus dwelt on the fact that of the 100,000,000 tons of freight brought into the city, 27,000,000 tons are hauled by drayage in the city, and speedier and more economical methods are needed, the average cost at present to haul one ton through the city is equal to the cost to haul by train 400 miles.

The plan includes a gravity yard in New Jersey west of the Bergen Hills, from which, after classification, the small standard-gauge cars will be brought under the river and up a line extending along the North River from the Sixtieth Street yards of the New York Central to the Battery, and up the East River to connect with the railroads in the Bronx. It is expected that ninety per cent of lower New York's freight can be handled in this way. There would be a crosstown line at some convenient point north of Twenty-third Street, and there would be facilities to carry passengers in the subway.

Mr. Wilgus went into the objections against the plan, and suggested remedies. Representatives of commercial and civic organizations argued generally for the end for which the subway is proposed, but objected to some of the locations traversed, and suggested extensions to cover outside territories in order to relieve the factory congestion of lower New York.

A proposed substitute for the Wilgus plan was a combined subway and surface road along the West Side water front similar to the arrangement in many of the European cities. General discussion followed.

Pennsylvania Electrification.

It is stated that the Westinghouse Electric and Manufacturing Company will not begin the building of electric locomotives for the Pennsylvania Railroad for several weeks. No definite decision has been reached as to whether the third-rail or single-phase system will be used, although an agreement will be reached in the near future.

The contract with the Westinghouse company calls for the electrification of the Pennsylvania terminals at Long Island, Manhattan and Jersey City. Electric trains will be operated as far as Harrison, N. J. It is probable that the Pennsylvania will eventually install electricity on its lines between New York and Philadelphia.

ELECTRIC HEATING.

231ST MEETING OF THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS, NEW YORK CITY, NOVEMBER 13.

The 231st meeting of the American Institute of Electrical Engineers was held in the Engineering Societies Building, New York, N. Y., on Friday evening, November 13. The meeting was called to order by President Louis A. Ferguson, and Secretary Pope announced that at the meeting of the Board of Directors held during the afternoon there were fifty-nine associates elected. It was also announced that the new by-laws had been revised and would go into effect. These will be circulated as soon as they can be printed.

The paper of the evening was on the subject of "Electric Heating," by W. S. Hadaway, Jr. An abstract of this paper follows:

The term "electric heating" is commonly used to express the filtering down of a higher potential energy of electricity into the lower potential energy of heat. Mr. Hadaway considers that the expression, "electricity, a factor in a telethermic system," would be a better definition.

Heat energy is to be regarded as a commodity that can be generated and controlled in convenient form, and distributed and sold, and in which electricity is used either directly as the high-potential heat factor, or indirectly as an agent. The feature of the subject under consideration is the practical adaptability of commercial electricity for heating purposes and for performing useful work under the conditions imposed in general industrial and domestic life. These applications may be roughly divided into two classes, according to the degree of concentration of the heat energy used. The first class includes low-temperature heating, generally diffused and in large volumes. The second class includes high-temperature heating, generally localized and in small quantity.

The electrical unit, or kilowatt-hour, is the equivalent of 3,412 British thermal units. For practical purposes the work in hand is to determine the useful work in different lines which is obtainable from this number of heat units at a fair average cost of supply.

It has been determined that with a platinum wire held in a flame less than 0.5 per cent of the thermal energy produced in the flame was transferred to the wire, while ninety per cent of the electrical energy used appeared as heat. In another case an iron bar weighing about twenty pounds was heated by charcoal and then by electricity. In the former case about 0.75 per cent of the thermal energy was transferred to the bar, and in the latter case eighty-eight per cent.

In room-heating apparatus on continuous run we may estimate that one watt-hour (3.41 thermal units) will heat one square foot of common radiator surface through 1.26 degrees Fahrenheit; that 1,000 watt-hours, or 3,410 thermal units, will heat the surface approximately 126 degrees Fahrenheit above the room temperature. That is, for room heating from eighty-five to 100 watt-hours are practically the equivalent of steam at low pressure, condensed by one square foot of radiator surface, with the difference between the room and the radiator temperatures as above stated. We may safely assume that a fair average price of the electrical unit from large steam-electric stations is 6.7 cents. It would, therefore, cost 0.65 cent, average, to run one square foot of direct radiation surface for one hour, or the electrical unit would keep about 10.3 square feet of radiator surface at the temperature difference noted for one hour.

The steam-driven electric-light station ranks low as a heat distributor for house warming on any considerable scale, yet notwithstanding the great disparities in the cost of heat energy on a large scale, the uses to which small electric air-heaters are put are surprisingly numerous.

It is then on a comparatively small scale, and in intermittent service, that the electric air-heater is useful when power is derived from the steam-electric station, and when the heat supply is derived from electric resistance.

We must not under-rate the facility with which gas may be stored, the economy of rapid and continuous generation and available heat from combustion and discharges of by-products; whereas, in electric lighting and electric heating every unit of heat and light secured represents an appreciable loss or depreciation of the energy converter. It may be safely concluded that we cannot afford to use electricity for general diffused heating purposes on a large scale. Practical experience, however, shows that such deductions may lead to unsafe conclusions. Many practical illustrations are found, which show that no great engineering difficulties are encountered in distributing boiler energy, and also exhaust steam from the engine, for useful heating work at a distance. We are now able to formulate a multi-potential heat-supply system in which the steam, either live or exhaust, or both, is used for low-temperature work, and electricity from generators in the same station is employed for all work requiring temperatures in excess of that of the steam—that is, from about 250 degrees Fahrenheit upward. In domestic work the steam heat would be employed for house heating and water heating, for bathing, laundry and cooking purposes. Electric heat would be used for lamps, ovens, broilers, small stoves, sad-irons and all purposes requiring high-temperature localized heat. A total fuel efficiency exceeding thirty-five per cent for both low and high temperature heating is obtainable, and probably a still higher efficiency may be secured from operations on a large scale. It is in this direction that we must look for the best immediate results of electric heating in domestic life. Electrical engineers realize that the ordinary light and power station is wasteful as a heat generator and distributor, and one of the ways to improve these conditions is to introduce a basis of supply in which the load-factor is a larger percentage of the station capacity, and in which low-temperature steam distribution may also be utilized. In the modern apartment house we find it possible to effect a comparatively high distributive heat efficiency. The rooms are heated by low-pressure steam or hot-water radiation, and the hot water for laundry, bath room and cooking purposes is also supplied. Electric lighting is available, but low-heat efficiency is found in cooking except in cases where gas is available. No one can question the value of gas as a fuel in cooking. We may, however, take the ground that when a boiler plant is required for room and water heating, and an electric plant for lighting, the use of gas in cooking is unnecessary and comparatively expensive, for it is a form of heat supply not as effectively localized as electricity, and is accompanied by many disagreeable features. In these houses electricity is already in use instead of alcohol for heating convenience, also for heating sad-irons for laundry work and pressing; and it appears to be a question of time only when electric ovens and other cooking utensils will replace the range or the gas stove on a considerable scale.

There are some installations in which all or nearly all the cooking is done by electricity. These are generally successful and economical, according to the degree to which extensive water heating is eliminated. Laundry and pressing irons are found almost uniformly satisfactory. Some of the devices used in the dining room are accounted great conveniences when electrically heated. When it comes to the kitchen the same feeling of cleanliness and refinement of methods as for the dining room is expressed and hoped for, but the housewife is not so ultimately in contact with the apparatus, and ignorant manipulation is encountered, which, however, does no other harm than to add to the expense of running.

In industrial work the progress of electricity has been more rapid than in domestic applications, with the exception of the electric sad-iron. There are cases where heating by electricity is found cheaper than by fuels, setting aside all collateral advantages. In electric cars the more equitable distribution of heat on a satisfactory basis of effective warming is sufficient to employ the method and apparatus even at considerably greater cost than former methods of heating.

Following the reading of this paper, President Ferguson announced that two written discussions had been contributed by Charles E. Waddell, electrical engineer of the Biltmore Estate, Asheville, N. C., and by W. N. Ryerson, superintendent of the Ontario Power Company, Niagara Falls, Ontario. Percy H. Thomas abstracted these contributions.

Mr. Ryerson considers that Mr. Hadaway's suggestions concerning the limitations of the use of electricity for maintaining an equitable temperature in buildings during the season of cold weather are undoubtedly to the point at the present time. There are instances, however, in which comparison between the use of electricity and other heating agents on the basis of cost leads to erroneous conclusions. As an instance in point, in the office building of the Ontario Power Company, at Niagara Falls, which was equipped, under the plans of the architects, with a low-pressure steam-heating system having an auxiliary hot-water system with forced draft, it has been found that the low-pressure steam system is entirely unnecessary, a comfortable temperature being maintained in the coldest weather by an electrically-heated hot-air system designed by himself. It is true that the steam-heating system in this building is a part of a much more extensive one installed throughout the transformer building, of which the office forms an ell, but it is not necessary to maintain a high temperature throughout the remainder of the building, with the exception of the switchboard room, which is heated by direct electric radiators. During the last winter it was found that the use of the boiler was only necessary for twenty-five days, and during the remainder of the time the electric heaters in the office building and switchboard room were sufficient for all purposes. The cost of this electric heater was $388, and it consumes eighty-five kilowatts, including power necessary for a fan motor. In a plant of this size the cost of this amount of energy is negligible, whereas with natural gas and wages of boiler attendants, a large cost would be built up. The electric heater supplies 72,000 cubic feet of air space in a building exposed on three sides.

The Ontario Power Company purchased and installed a complete electric kitchen capable of cooking a meal for 300 persons, and its successful use has been demonstrated on several occasions.

Mr. Waddell considered that dividing heat applications into low-potential quantity and high-potential intensity types is a very expressive way of classifying two general conditions. In high-potential heating problems it has been demonstrated that the cost of electrical energy has little or no bearing on economy. Other factors enter that more than compensate for any discrepancy in calorific value between electricity and fuels.

It is doubtless true that the steam power plant, by reason of its low efficiency, is debarred from furnishing electric heat in competition with fuels. In the case of a thickly-settled district the use of exhaust steam for heating has been demonstrated as profitable and desirable. As Mr. Hadaway suggested, conditions may be such that it might be profitable to generate electricity for high-potential applications and use the exhaust steam for quantity work.

In house heating the efficiency of the apparatus depends almost entirely on the range of temperature in the apparatus and on the method of controlling the fires. Another point that has impressed Mr. Waddell is that not only the quantity, but the intensity of heat in domestic applications is essential to success. If electric heating is to be introduced on a large scale into house warming, it will be necessary to accord the art of heating and ventilation more scientific attention than is now usually bestowed upon this class of work. Unquestionably, of the quantity of heat annually radiated in domestic installations, the greater portion is wasted.

President Ferguson called upon W. S. Andrews to continue the discussion.

Mr. Andrews said that it had been his privilege to be associated with Mr. Edison while he was developing his low-tension, multiple-arc system of electrical distribution in the early eighties. He distinctly remembered a statement which Edison made in 1881, to the effect that he expected to utilize the general distribution of low-potential electrical energy not alone for public and private lighting purposes, but also for operating electric motors, to drive machinery in mills and factories, and for electric traction; and furthermore, he confidently expected to make electricity generally serviceable for the cooking of food, and, to a limited extent, for the warming of dwellings. Mr. Andrews agreed with Mr. Hadaway that the real difficulty in using electricity for performing ordinary cooking operations exists in the providing for a hot-water supply economically. At a price of five cents per kilowatt-hour the cost of heating a gallon of water from faucet temperature to boiling point, at an efficiency of, say, eighty per cent, is a little more than two cents, which, to many people, would be a prohibitive price, especially as the same result can be accomplished for very much less money. Apart from the question of water heating, the operations of baking, broiling, frying, toasting, etc., by electricity can be accomplished at a reasonable expense when electricity is sold at the rate of five cents per kilowatt-hour. Taking into consideration the collateral advantage of being able to raise utensils to a high temperature with localized heat, thus keeping the kitchen much cooler in hot weather than is possible when using a coal or gas range, increases the advantage of electrical service.

James I. Ayer said that the paper of the evening should be analyzed and a more optimistic view taken of the possibilities of electric heating. Mr. Ayer considers that the likelihood of the use of steam from a central station proving an important factor in developing electric heating is doubtful. Steam heating from electric central stations is not considered by those who are exploiting such systems as something they can recommend generally, and the limitation of such development has been in no manner affected by electric heating.

Concerning the competition between gas and electricity, remarkable results in development have come about. In this struggle electric heating already plays its part to a limited, though very beneficial, extent. With no important single installation of electric heaters exceeding a few kilowatts, one central station reports a total of 1,560 heating devices on its lines, having 696 kilowatts' capacity, producing an increased load of 132,000 kilowatt-hours per year, and a gross revenue for the service of $18,000, practically all at lighting rates.

Paul M. Lincoln said that electric heating must compete with other means of arriving at the same end. To win out, the electrical method must show a higher efficiency than any other method of obtaining heat. One of the big advantages with electrical apparatus is, of course, that it can be applied to the work in a much better way than by any other method.

H. P. Ball said that it was feasible, by using modern materials such as nickel-chromium wire and infusible materials, to get a very high temperature, and this was what was needed. In heating rooms, the use of a resistance conductor in the form of a thin, wide band, so as to have a maximum radiating surface, is necessary.

Max Loewenthal said that there can be no doubt that electricity converted into heat cannot be as efficient for any operation as steam generated from fuel. Again, as a general proposition, electricity converted into heat is not commercially as efficient as gas. On the other hand, figures are available which show that the electric oven, for example, compares very favorably with an oven in which solid fuel is burned. When it is considered that the fuel burned in a coal range delivers only 2.5 per cent of the thermal value of the fuel for heating the food, and in a gas stove, from three to 3.5 per cent is secured; while with the electric oven, considering the conversion of energy from steam energy into electrical energy, and assuming an efficiency of the oven of about eighty-five to ninety per cent, the percentage with electricity runs up to 4.5, the economical advantage can be seen. Making careful calculations, based upon actual figures, if the rate for electricity is reduced to 2.5 cents per kilowatt-hour, it will be identical with gas at $1 per thousand cubic feet. The final solution of the problem of using electricity for general heating will be found when the central station can reduce the cost of current to where it will be as economical to cook with electricity as with any other means.

As far as the technical development is concerned, Mr. Loewenthal believes that the resistance material will be of a refractory character more in the nature of a carbide. Samples have just been received of a European product for heating purposes—a silicate of carbon—which may be heated for a great many hours without showing any deterioration at all.

Dr. C. P. Steinmetz took up the discussion and indicated the disadvantages and handicaps under which the development of general electric heating labors. The solution of the practicable utilization of electricity for heating leads up to a method of transforming heat energy from high-pressure, low-quantity, to low-pressure, high-quantity. If you admit heat at a high temperature, a small quantity expanded down is converted into mechanical energy. By going from very high temperature to low temperature, probably fifty per cent can be converted. Carrying out the reverse process at lower temperatures, an amount of heat quantity units several times larger than the heat quantities put in at the higher temperature can be secured. Heat energy is convertible into any other form of energy or fixed equivalent of heat, but heat quantity corresponds to quantity of electricity, corresponds to current, and has no direct relation to energy, but is one of the factors of producing energy. The smaller the electromotive force, the larger may be the other factor with the same amount of energy. This mixing up is partly due to the nature of the energy transformation between chemical energy and heat energy. If we interpose the electric transformer or converter, and change from high electromotive force and small current to low electromotive force and high current, we can get a much larger output by using a much larger quantity of electric energy.

Mr. Hadaway, in closing the discussion, stated that it had been his desire to make his paper very conservative, and that, in his opinion, the thing to be considered mainly was the confining of the heat.

Before adjourning, President Ferguson stated that the next meeting of the Institute would be extremely interesting, the subject for discussion being the experiences in the electrification of the New York, New Haven & Hartford Railroad. The paper would be presented by W. S. Murray, chief electrical engineer of the system.

The meeting was then adjourned.

Reorganization of New York Metropolitan.

It was announced on November 13 that the problem of reorganizing the finances and properties of the Metropolitan Street Railway Company, in New York city, will be taken up at once by a committee representing the bondholders. The committee's work, which will require, as a preliminary, a thorough analysis of the financial and physical factors involved, will be prosecuted, it is promised, with the utmost speed, with the object of evolving a comprehensive plan of readjustment.

Both the committees representing the general and collateral five per cent bonds and the refunding four per cent bonds of the Metropolitan Street Railway Company are represented in the Reorganization Committee, which consists of four members. Donald Mackey and William P. Dixon represent on the joint committee the general and collateral mortgage five per cent bonds, and John W. Castles and Otto H. Kahn the refunding fours. In addition to these, Alexander J. Hemphill, chairman of the first-named Bondholders' Committee, and E. S. Marston, chairman of the latter, have been designated by their respective committees to act, ex-officio, in an advisory capacity to the joint committee. John W. Castles has been named chairman of the committee and Alexander Hemphill, secretary, with L. C. Krauthoff as counsel.

Civil Service Examinations for New York State and County Service

The New York State Civil Service Commission will hold examinations on December 12 to fill the position of junior draftsman, Public Service Commission, First District, $720 to $1,200 per annum. The last day for filing applications for this position is December 5. Full information and application forms may be obtained from Charles S. Fowler, Chief Examiner, Albany, N. Y.

Association of Car-Lighting Engineers.

First Annual Meeting Held at the Grand Pacific Hotel, Chicago, November 16 to 20.

The first annual meeting of the Association of Car-Lighting Engineers was called to order on Monday morning, November 16, in the German Room of the Grand Pacific Hotel, Chicago. There was a large and enthusiastic attendance, and the opening session indicated that this was a very live organization, and that there was in store for it a future of much service and value to the car-lighting engineers and the railroads with which they are connected.

The opening session was called to order by President A. J. Farrelly, of the Chicago & Northwestern Railway. Mr. Farrelly rehearsed very briefly the organization of the association. On May 20 last ten men, representing four of the large railroads, gathered together at Ogden, Utah, to discuss several points of difference which had involved the different organizations, and during the discussion it was suggested by E. M. Cutting, of the Southern Pacific, that an organization of car-lighting engineers be started. In response to some correspondence which was then carried on, a meeting was held in the Grand Pacific Hotel, in Chicago, last August, with about forty men present, and an organization effected with the following officers: President, A. J. Farrelly; first vice-president, E. M. Cutting; second vice-president, A. J. Collett, Union Pacific; secretary and treasurer, G. B. Colegrove, Illinois Central. Executive committee—H. C. Meloy, Lake Shore & Michigan Southern; A. C. Terry, "Soo;" G. W. Murray, San Pedro, Los Angeles & Salt Lake, and O. W. Ott, Oregon Short Line.

The objects of the association are to tie together the loose threads which have predominated in car-lighting engineering. While the apparatus has been standardized and perfected to a considerable degree, there is but little uniformity of installation and equipment. Except on a few of the larger roads there has been a tendency to utilize any kind of a light, in any kind of a way, and let it go at that. It is the opinion, however, of progressive railway men that one of the greatest features of attraction in railway service is adequate lighting, and to-day there is need for considerable study and interchange of ideas which would bring about that betterment of service for which all car-lighting engineers should strive in performing their full duty to their employers.

The report of Secretary-Treasurer Colegrove showed that there were 205 members; that the collections had amounted to $410, and that the expenditures outside of the cost of printing for the present convention were $108.65, leaving a balance in the treasury of $301.35.

The first paper was read by Patrick Kennedy, entitled "History of Car Lighting." This paper called attention to the valuable contributions to the literature of train lighting which had been made by Prof. George A. Shepardson, of the University of Minnesota, and by A. H. Bauer. The advantages of electrically lighting railroad cars were realized very early in the development of incandescent electric lighting, and the efforts of electrical engineers to utilize electric lamps for car illumination were contemporary with the earliest manufacture of incandescent lamps. Prior to the installation of the first Edison system in New York the London & Brighton Railway operated an electrically lighted car from a battery of Faure cells. The Pennsylvania Railroad, in the spring of 1882, equipped a number of its cars, taking current from imported Faure cells, and considerable experimentation was done with primary batteries for car lighting from 1883 to 1887 in France and America. It was recommended that a committee be appointed to prepare a complete historical treatise dealing with the subject of car lighting by electricity.

In the course of his paper, Mr. Kennedy called attention to various patents which had been granted for systems of car lighting. One of these, he said, consisted of a windmill, which was placed on the locomotive, and which was expected to generate enough current to light the train and perform some other service.

During the remarks which followed the reading of Mr. Kennedy's paper, it developed that Alexander McGary, chief electrician of the New York Central, was the expert who undertook the testing out of this installation. Notwithstanding the fact that this is now looked upon as more or less of an absurdity, it was nevertheless practicable, and it appeared at that time that a large syndicate would be organized to develop it. The installation consisted of a thirty-six-inch Sturtevant wheel equipped with a damper gate for cutting off the wind pressure as the locomotive would meet a new slant of the wind when rounding a curve or changing its direction. It was installed on a locomotive on the Grand Rapids & Indiana, running between Grand Rapids and Muskegon, Mich. The generator developed twenty-five amperes at eighty-five volts. Of course, with the controlling devices at that time available, it was not possible to regulate the voltage or maintain anything like decent illumination, and pending the construction of a better form of wheel and controller, the development of this system was allowed to lapse.

A paper entitled "The History of Axle Lighting" was presented by W. L. Bliss. This was a classical resumé of the past and present efforts made in the development of a successful axle lighting system. Mr. Bliss paid a warm tribute to those who had, along with him, done the pioneer work in bringing to the present-day perfection the system of axle lighting with which large numbers of cars are now equipped. He described the many difficulties which were overcome, and indicated the probable trend of invention and design in meeting those difficulties which it is now considered are about to be solved. The history of axle lighting is as old as any development of car lighting. From the earliest days efforts have been made to light trains electrically by means of a generator driven from the axle through some form of transmission. The first patent with which he had any acquaintance was taken out in England in 1881, by Richard Lalor, and is numbered 5,316. In America he thought that among those men who were now living, and who had been interested for the greater part of their lives in developing a system of axle lighting, in point of time of service the leader was Morris Moskowitz; that second place belonged to Patrick Kennedy, and that he himself was entitled to third place.

Mr. Bliss illuminated his paper with many amusing reminiscences and references to the early work of inventors, and made a number of excellent suggestions concerning the perfect system of train lighting which now is in fair shape to be realized.

The session then stood adjourned until 2 p. m.

The afternoon session was opened shortly after 2 o'clock, when President Farelly announced the report of the committee on the care and maintenance of storage batteries, comprised of F. R. Frost, W. F. Bauer, Dr. J. E. Widner and H. M. Beck. The paper was read by the first named, as chairman. Though the report was not lengthy, it was very comprehensive, and in a terse way set forth a great amount of valuable information concerning the storage battery and its use.

After an introductory paragraph, in which the systematic and intelligent attention to batteries at frequent intervals was strongly advised, the authors struck at once into the controversy of lead-lined tanks versus rubber jars, by summing up the following advantages for each class of container. Over the rubber jar the lead-lined tank prevailed, they declared, in its ability to withstand severe shocks, its slightly lower first cost, the value of its salvage as scrap and the greater ease of repair. On the other hand, rubber jars were stated to weigh less, to require no special care to prevent the action of wood, acids and grounds, to need no insulation to prevent short-circuiting the elements, and to show a lesser tendency for the electrolyte to creep.

The following suggestions were made for battery cell construction used in railway train-lighting work: Rubber jars were recommended to be three-sixteenths inch thick, with reinforced tops and with bridges not less than one and three-fourths inches thick. Lead linings should be made of lead weighing not less than four pounds per square foot with all laps burned, the use of solder not being permissible. Oak crates with dovetailed corners were advised, thoroughly painted inside and out with an acid-resisting paint. Jars and linings should be set in a low-melting compound, the report said, permitting of their easy removal when filled with hot water. Connectors of No. 4 or No. 6 cable, containing at least forty-nine strands and insulated with best quality rubber, were advised. For terminals brass is inferior to copper. All metal parts in the battery box must be painted with an acid-resisting compound.

For washing batteries the use of water was discouraged, as it tends to make the negative plates lose their charge. In changing plates from one electrolyte to another the elements should be kept out of the acid as little as possible. One or more cells of a series, showing up weak should be removed from circuit and treated until the normal condition is restored; meanwhile other good cells take the place of the weak cells in the working circuit. A weak cell will quickly go to pieces if continued in service, particularly if the battery is discharged to a low point as the cell may become reversed. In the use of the pilot-cell method great pains must be taken to keep the electrolyte conditions of the group uniform. Other directions for taking care of cells in and out of service were given with some detail, and a complete system of recording tests, cleanings and renewals was recommended to be observed with care.

Interesting from an historical and curious standpoint was the next paper, "Railway Train Lighting," first delivered before the American Institute of Electrical Engineers at Chicago in June, 1892, by A. H. Bauer, the father of W. F. Bauer, a member of the convention. The paper was read before the car lighting engineers by Mr. Bender. A brief abstract of the matters of historical importance contained in the paper is given below:

The first successful system of railway train lighting was that invented by Houghton and adopted by the London, Brighton & South Coast Railway of England, in 1881. Other improvements added by many inventors later made the system almost automatic. Connected by link belting to the car axle, was a Brush dynamo in the baggage car. A ball governor, rotating vertically, performed the following functions: Opened a switch when the electromotive force of the generator fell below that of the battery, adjusted a resistance to maintain the current constant, shifted the brushes to conform to the neutral point at the particular speed of the armature. The pole changer, designed to make the machine pick up in whichever direction the car should run, consisted of a freely moving rocker-arm carrying the brushes and able to be moved through a quadrant by the friction of the brushes on the commutator, at the same time operating a throw-over switch controlling the connection of the field coils. The rocker-arm was brought to position by a snap-spring arrangement: One set of accumulators, consisting of twenty-five cells, was provided for each train and placed in the baggage compartment. The maximum number of lamps in a train was seventy, of ten candlepower each, at fifty volts.

Axle-lighting seemed to have failed in America, the author observed in 1892, since the bogie truck used in this country did not allow a stable arrangement of the pulley, belt and axle, as was possible on the rigid wheel bases of Europe.

In 1887-88 the first attempt was made to use secondary or storage batteries in lighting two Pullman limited trains of six cars each. Each car was equipped with thirty cells, weighing fifty pounds per cell. Duplicate sets were kept charged at each end of the line and exchanged for the exhausted battery on the car. Twenty-six sixteen-candlepower lamps, operating at sixty volts, were used per car. This system failed because the capacity of the battery was too small and the cells were usually exhausted before 11 p. m. Another reason was the deterioration of the plates, which were of the pasted-grid type.

In 1890, four cars, each equipped with thirty-two cells of 150-ampere-hours capacity, and containing twenty-six sixteen-candlepower, sixty-volt lamps, were running between Chicago, Indianapolis and Cincinnati. The cars were charged at one end of the run while standing on a particular sidetrack near the generating station.

In January, 1888, six-car trains between Jersey City, N. J., and Jacksonville, Fla., were lighted by a vertical single-stroke engine, belt-connected to the generator in the baggage car. Steam from the locomotive boiler was used. A three-cylinder engine direct-connected to a seventy-five-volt, sixty-ampere dynamo run at 1,000 revolutions per minute was next installed. However, metallic dirt from the brakes and roadbed formed such frequent short-circuits that an extra armature was always carried and changes sometimes made while the train was in motion. Later the Eickemeyer dynamo, which was of an enclosed construction, was installed with success.

The cost of such a complete installation, with batteries, was figured at $5,808 per train, or $968 per car. "So successful has been the lighting of these trains that it is rare for other sources of illumination to be used," says the author in appreciation of the advantages of electric lighting. "There is no doubt," he concludes, "that the ideal way of running a dynamo is by connection with the axle. * * * It is, however, thought that within the next year a reliable connection will be had, after which I believe the lighting of railway trains by electricity will be universally adopted."

Following the reading of Mr. Bauer's paper, the convention took up the discussion of storage batteries and was soon engaged in a spirited dissension on the relative value of the rubber jar and the lead-lined tank. The charge made that rubber tended to crystallize and become brittle with age was denied by those who had experienced success with pure and compound rubber jars. Methods of crating and handling, all agreed, had an important part in the resultant breakage during service.

On Tuesday morning an effort was made to crystallize the results of the preceding day's discussion on the relative advantages of the rubber jar and lead-lined tank and the construction of battery trays by obtaining a vote on a resolution embodying the recommendations of the majority of the car-lighting engineers present. A resolution declaring that reinforced rubber jars set in petrolyte or some suitable material are superior to lead-lined tanks failed to pass by a single vote, the convention dividing almost equally over the merits of the respective containers. A unanimous vote was accorded the general resolution to the effect that the materials of which trays are to be made is largely governed by local conditions.

The report of the committee on "Straight Electric Lighting" was then read by C. W. Bender of the Pennsylvania Railroad. J. R. Sloan and A. McGarry were associated with him in the preparation of the paper. The report discussed the necessity for auxiliary methods of lighting trains, except the provision of emergency candles, under the varying conditions met in straight-storage, axle-generator and head-end systems. In the first case the batteries must be of ample capacity, and sufficient time for charging must be given at layover points.

In the committee's opinion the axle generator and steam turbine have been developed to such a point that with competent inspection they will give satisfactory service. The report cited the instance of one railroad operating several hundred electrically lighted cars, these cars being equipped either for straight-storage, axle-generator or head-end system, and on which, with very few exceptions, there is no auxiliary system of lighting other than emergency candles, and the failures of electric lights are gratifyingly small. The majority of those that do occur are on account of insufficient layover time and inadequate charging facilities.

In the general discussion which followed the confidence of the engineers in unreinforced electric lighting was evident and the experiences of the members showed that practice now leans toward straight electrical installations. Sole dependence on the system and a better routing of cars for electrical inspection and repair were shown to make for reliable operation of electrical equipment. The percentage of gas failures, it was concluded, is about equal to the electrical outages observed. Several engineers advised incorporating rules regarding attention to fuses and lights, in the book of train rules for the crew, and requiring examinations.

Some very interesting remarks by two outside visitors enhanced the afternoon session. Wilson E. Symons, who has been prominent in railroad development and maintenance work, attended the meeting and was called to the front of the room, where he read several extracts from a paper delivered before a technical society earlier in the year, apropos the passing of the steam locomotive. After a brief history of electric traction Mr. Symons congratulated the members of the Association of Car Lighting Engineers on the splendid work before them and predicted that as an authoritative body the association would achieve a position only second to the Master Car Builders.

A. H. Darker, of the J. Stone Company, Deptford, England, was next called upon and surprised the convention by his account of the progress of car lighting elsewhere than America. He reported that 30,000 cars equipped with an axle-lighting system were used in the civilized and comparatively unsettled countries of both hemispheres. Potentials of sixteen. twenty-four and sixty volts are common practice abroad. The severe handling in Europe, where cars penetrate half a dozen different countries during the shifting of a week, is an extreme condition which American car-lighting men are not called to meet. Instruction cards must be printed in several different languages. Electrical car-lighting with no auxiliaries has been found absolutely reliable in the extensive practice of Mr. Darker's company.

The report of the committee on train connectors, read by H. C. Milo, one of the committee with A. McGary and J. R. Sloan, involved a technical discussion of a device which, the members' remarks implied, is not yet entirely satisfactory.

E. W. Jensen, chairman of the committee on organization and systemization in connection with electric-lighted trains, followed with the report prepared by himself and his associates of the committee, W. Barnum and F. McGary. The first part of this paper was taken up with a compilation of report forms used in recording materials, renewal and inspection. Several examples were given of the force necessary to handle electrical equipment. For instance, one road has the major portion of its cars equipped for lighting from straight storage battery and its limited trains lighted with a turbine head-end system. At one terminal, ninety cars per day are handled, of which fifty-eight are straight-storage, twenty-four head-end and eight axle-lighted. There is a force of one electrician in charge, one assistant electrician, one clerk for records and correspondence, one storeroom clerk, four electrical machinists for turbine work, axle generator work and general repairs, four yard electricians for testing and charging batteries and twelve batterymen, who make all battery repairs, clean and supply the different sets of battery. At this point the majority of the cars are cleaned and repaired.

Sessions were held on Wednesday and Thursday. The annual banquet was held on Wednesday evening, and the programme called for a jaunt to Milwaukee on Friday.

A number of exhibitors occupied parlors on the convention-hall floor of the Grand Pacific Hotel, and several showed operating installations to claim the attention of the car-lighting engineers between the sessions. Exhibits of the following companies were shown: Consolidated Railway Electric Lighting and Equipment Company, the Willard Storage Battery Company, the Westinghouse Machine Company (storage batteries), Storage Battery Lighting Company, Central Electric Company, Bliss Electric Car Lighting Company, the Safety Car Heating and Lighting Company, the New York Leather Belting Company, the National Electric Lamp Association (engineering department), the Gould Car Coupler Company and the Bijur Battery Company.

Chicago Section—Illuminating Engineering Society.

The second fall meeting of the Chicago Section of the Illuminating Engineering Society was held at the Grand Pacific Hotel on the evening of November 12. After the usual dinner the meeting was devoted to a discussion of some of the papers that had been presented at the recent annual convention of the society at Philadelphia. These papers were recently abstracted in both the ELECTRICAL REVIEW and the WESTERN ELECTRICIAN.

The first paper considered was that of Leonard J. Lewinson on "The Intensity of Natural Illumination Throughout the Day." It was briefly abstracted by Albert Scheible. In the discussion J. R. Cravath gave an explanation of why the author could not read his instruments with an illumination of two foot-candles at dawn. Mr. George H. Jones spoke of the marvelous range of the eye, which can adapt itself with comfort to variations in illuminating intensity from a small fraction of a foot-candle to over 10,000 foot-candles.

A paper by J. R. Cravath and V. R. Lansingh on "The Calculation of Illumination by the Flux of Light Method" was then abstracted with great care by Mr. Cravath. He demonstrated graphically the various steps that led to the development of this method and showed how it can be used. There was no discussion of this subject.

Consideration was then given to the paper presented by V. R. Lansingh and T. W. Rolph on "Some Experiments on Reflection from Ceilings, Walls and Floors." This also was abstracted by Mr. Cravath, who showed a graphic chart prepared from the results given in the paper as to the watts per lumen required to illuminate a working plane in a room having, first, ceiling, walls and floor dark, then the ceiling light, next ceiling and walls light, and finally even the floor light. The discussion on this subject was quite general. Mr. Scheible thought that in the first case the use of a mirror type instead of a prismatic reflector would have shown even more striking a contrast in the figures with and without reflector. It was also pointed out that for the case with floor dark there was little difference between the use of a reflector and not using one. The figures for the last case were said to be now quite commonly attained by the use of tungsten lamps.

The next meeting of this section will probably consider some problems relating to illumination by gas, as its date coincides with the holding of a "Gas Show" that is scheduled for the First Regiment Armory.

New York Section—Illuminating Engineering Society.

The regular monthly meeting of the New York Section of the Illuminating Engineering Society was held on Thursday evening, November 12, at the St. Gabriel's Branch Carnegie Library on East Thirty-sixth Street.

The object of holding the meeting at the library was twofold, one being to give the members an opportunity to examine and discuss the lighting installation, and the second that the designer has the benefits of the discussion in the designs of similar buildings now under construction.

The illumination of the building was designed by the first president of the society, L. B. Marks, and the installation was described with measurements of the illumination in a paper presented at the recent convention at Philadelphia.

The meeting was called to order by Albert Wahle and the installation was described briefly by Mr. Marks. The visitors were quite as numerous as the members, including the chief of the circulation department of the New York public libraries, Mr. Bostwick, and a number of the librarians in charge of the various branches throughout the city.

A feature of the lighting of this building was that it was the first to be erected where local lighting was provided.

Prof. Morgan Brooks of the University of Illinois cited an instance where there was sufficient illumination for reading, but that upon some of the tables reading lamps were provided and the students invariably selected these tables. He thought the reason for this was that it was the attractiveness and coziness, as he expressed it, of a table lamp.

The installation was also discussed by Messrs. Doane, Lansingh, Moore, Barton, Owens, Wahle and Millar.

From the discussion it would be hardly fair to state that this particular type was altogether successful, although none of the members mentioned an installation where only general lighting was provided where results were as satisfactory as in the case under discussion. The members were the guests of the Librarians of the city, and through their hospitality refreshments were enjoyed by all.

More Westinghouse Stock.

A special meeting of the stockholders of the Westinghouse Electric and Manufacturing Company was called on November 11, to meet in Pittsburg on November 24, to provide for the carrying out of the reorganization plan. The stockholders will be asked to increase the board of directors to sixteen and to constitute a proxy committee, to remain in existence five years, according to the requirements of the modified plan of the Readjustment Committee, which is to take the company out of the hands of the receivers.

The stockholders will also be asked to make changes in the by-laws required by the plan and to increase the capital stock by $10,000,000, as well as to adopt the necessary resolutions to make the plan itself effective.

The requirements of the modified plan for the readjustment of the debt of the company will require approximately $14,200,000 of new assenting stock, to be issued to holders of the merchandise debt and bank debt and to stockholders who have subscribed for new stock in cash. Of the present authorized assenting stock of the company $12,500,000 is reserved against the convertible gold bonds and $23,940,000 is issued, leaving only $9,560,000 unissued.

Announcement is made that the Pittsburg banks have raised the $1,500,000 additional cash necessary to make the reorganization plan a success, by taking the notes of the Security Investment Company. The operation of the readjustment plan will give the Westinghouse company a total of approximately $12,000,000 cash.

The inquiries received by the Westinghouse company for electrical apparatus are larger than at any time in years past.

Electrical Supplies for the Navy Department.

The Bureau of Supplies and Accounts will open bids in Washington, D. C., on November 24 for the following electrical material: Miscellaneous cable, 6,000 feet lamp cord, two generator sets, 500 lamp guards, three transformers, 1,000 molded mica sockets, 1,000 porcelain wall receptacles, 11,400 feet weatherproof wire and miscellaneous wire, for delivery at Norfolk, Va.; 20,000 duct-feet vitrified-clay conduit, for delivery at Philadelphia, Pa.; fifty arc lamps and eight knife switches for delivery at Charleston, S. C.; 4,000 incandescent lamps, for delivery at Brooklyn, N. Y.

ALTERNATING CURRENTS AND THEIR APPLICATIONS.

BY EDSON R. WOLCOTT.

CHAPTER I. (PART VIII.)—POLYPHASE CURRENTS.

DISTINCTION FROM SINGLE-PHASE CURRENTS.

The alternating current heretofore considered is what is known as a single-

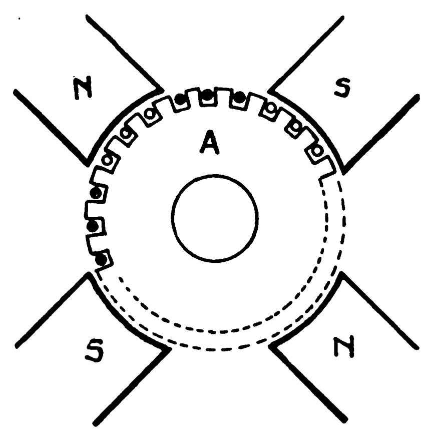

FIG. 19.—IDEAL TWO-PHASE GENERATOR.

phase current; that is, the generator delivering an alternating current to a single circuit. In the polyphase system the armature consists of two or more independent windings, each of which is connected through its own transmission lines to separate receiving circuits. Each independent circuit of a polyphase system carries a single-phase current, but these single-phase currents differ in phase, and the combination constitutes a polyphase

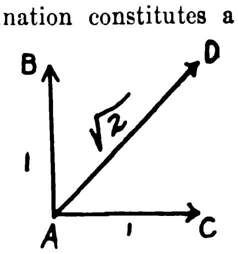

FIG. 22.—RESULTANT OF TWO QUANTITIES ACTING AT RIGHT ANGLES.

system. Two such separately generated currents differing in phase constitute a two-phase system; three separate circuits, a three-phase system, and so on.

The principal advantages of this system of generating and transmitting electrical energy are the better operation of motors and the economy secured in transmission. These two reasons for the steady increase in the use of polyphase systems will be considered in more detail under separate headings.

TWO-PHASE SYSTEMS.

In the two-phase system there are two distinct windings on the armature, each with its own collecting rings. They are so arranged that the electromotive force generated in one set of windings is ninety degrees out of phase with that generated in the other set. In other words, one is a maximum where the other is at its zero value. This is more clearly illustrated in Fig. 19. As shown by the projections marked N and S, there are two pairs of pole-pieces. A is the armature containing slots on its periphery, which carry the

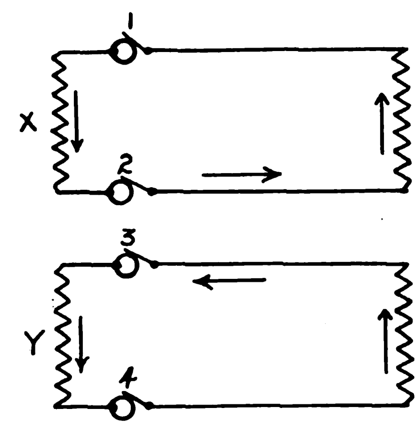

FIG. 20.—CIRCUITS OF TWO-PHASE ALTERNATOR WITH FOUR COLLECTOR RINGS.

armature windings. These are in two sets; those marked with a small circle are electrically distinct from those marked with a cross. When one set is directly underneath a pole-piece the other is midway between two poles, and accord-

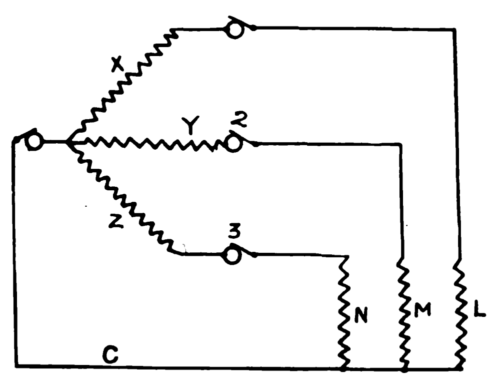

FIG. 23.—CIRCUITS OF THREE-PHASE ALTERNATOR WITH FOUR COLLECTOR RINGS.

ingly the electromotive force in one is a maximum when that in the other is zero, as already stated.

A two-phase alternator is usually provided with four collecting rings, as shown in Fig. 20, where X and Y represent the two separate windings of the alternator. Here 1 and 2 represent the collecting rings for the winding X, and 3 and 4 the collecting rings for the winding Y. The arrows show the directions of the current through the circuit while L and M represent the consuming apparatus, such as electric lamps, motors or the like. When used for motors L and M would represent separate windings in the armature of the motor.

THE THREE-WIRE TWO-PHASE SYSTEM.

It is possible to do away with one of the collecting rings by combining the two adjacent conductors of Fig. 20, as shown in Fig. 21. The two currents in the common return wire do not neutralize each other because they are ninety degrees out of phase with each other. The resultant current can be determined just

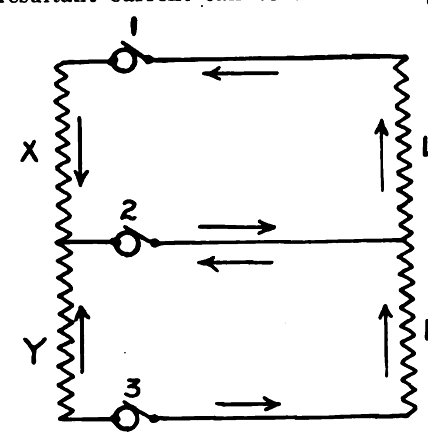

FIG. 21.—CIRCUITS OF TWO-PHASE ALTERNATOR WITH THREE COLLECTOR RINGS.

as the resultant of two forces acting at right angles is determined. Thus, as is shown in Fig. 22, AC represents the current from one winding; for example, X and AB the current from the other.

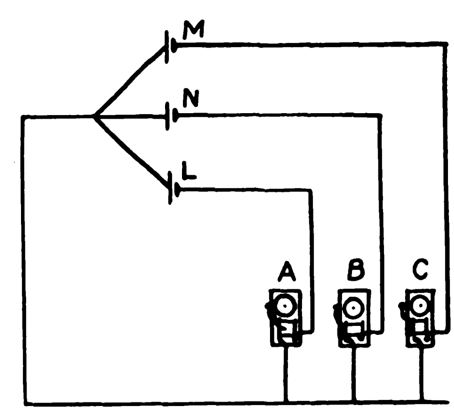

FIG. 24.—ARRANGEMENT OF CALL-BELL CIRCUITS WITH COMMON RETURN.

These two, differing ninety degrees in phase and being of equal magnitude, give the resultant AD, which is equal to $\sqrt{2}$ AC, or $\sqrt{2}$ AB. In other words, in a balanced load the current in the outside terminals of Fig. 21 being I, that in the common return is $\sqrt{2}$ I. Also, if L is the potential difference between one outside wire and the middle wire of Fig. 21, $\sqrt{2}$ E is the potential difference between the two outside wires.

THE THREE-PHASE SYSTEM.

In some cases it is preferable to use three-phase instead of two-phase current.

This can be arranged by having three separate windings in the armature of the generators connected to six collecting rings, making three distinct circuits and six transmission lines.

In practice, however, it is customary to combine these, as was done in the two-phase system illustrated in Fig. 21. One method of combination is by means of four wires and four collecting rings, as shown in Fig. 23, where the wire C acts as the common return of the others. Here X, Y and Z represent the three separate

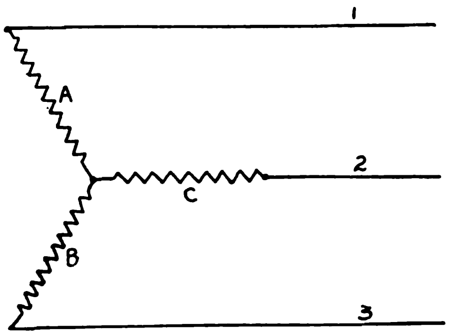

FIG. 25.—THREE-PHASE SYSTEM, STAR CONNECTED.

windings and L, M and N the receiving or consuming circuits, while C is the common return wire. This is similar to three electric-bell circuits having a common return, as shown in Fig. 24. A, B and C are three electric bells, each in a circuit with a battery, as shown at L, N and M respectively, all having a common return.

STAR OR Y CONNECTION.

It is possible to combine the four wires of Fig. 23 in such a manner as to use

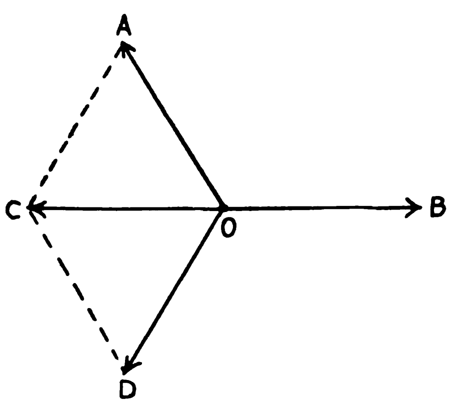

FIG. 26.—PHASE DIAGRAM SHOWING RELATION OF CURRENTS OR VOLTAGES IN A THREE-PHASE SYSTEM.

only three as shown in Fig. 25. The windings are then so arranged that the current flows toward the generator in one coil; for instance, Y, when it is flowing away from the generator in both X and Z. As will be shown by a vector addition of the current quantities, there would then be no use for the conductor C and the coils could be represented by A, B and C of Fig. 25.

The currents in a three-phase system differing 120 degrees in phase can be represented by the lines AO, DO and BO of Fig. 26. If the directions of the three currents at any one instant are as indicated by the arrows, CO, the resultant of AO and DO, is equal and opposite to BO. In other words, the currents in AO and DO exactly balance that in BO and a fourth wire is not necessary. This is called the Y or star method of connecting a three-wire three-phase system.

DELTA CONNECTION.

Another method of connecting the three wires of a three-phase system is known as the mesh or Δ (delta) system. This method is illustrated in Fig. 27. In this case the armature windings form a closed circuit, as shown by A, B and C. Each of the conductors 1, 2 and 3 carries

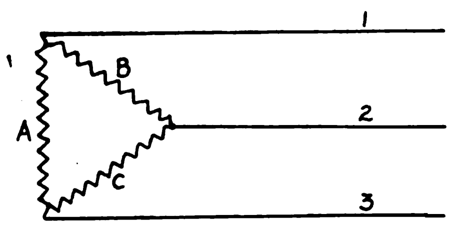

FIG. 27.—THREE-PHASE SYSTEM, DELTA CONNECTED.

currents 120 degrees out of phase with each other, and for this reason one coil does not form a short-circuit for the other two as it would if the currents generated in each coil were all in phase with each other.

Government in Favor of Lower Cable Tolls.

While the Post Office Department is watching with interest the agitation in Great Britain for lower cable tolls between the two countries, it has not yet discovered a way by which it can aid in the movement.

According to the officials, says the New York *Times*, the only way in which the Post Office Department could bring any pressure to bear on the corporations owning the cables would be through the charters granted them by this Government. These charters will be examined, and if it is found that provision is made in the documents for governmental supervision and control, some action may be taken.

Although the Government has not claimed it as a right, the transatlantic cables carry Government messages at special rates. Over the transpacific cable special rates on government business also rule, but these are the result of stipulations embodied in the government charter.

Postmaster-General Meyer is an enthusiastic believer in the establishment of the lowest possible rates on all means of communication between the United States and Europe. The two-cent Postage Convention between England and America entered into recently was framed and executed largely as a result of the Postmaster-General's belief that it would so increase the volume of mail matter that in the end the earnings would be in excess of what they were under the old rate of five cents an ounce.

No comment is made on the proposition of John Henniker Heaton, of London, that the Governments of the United States and Great Britain purchase the cables between the two countries and operate them.

Pittsburg Section of the American Institute of Electrical Engineers.

The regular November meeting of the Pittsburg section of the American Institute of Electrical Engineers was held on November 10, in the Carnegie Institute. W. Edgar Reed, chairman, presided.

Following the informal dinner held at the University Club, the attendance at the meeting was 138. The mining companies and the electrical profession in the entire surrounding district were well represented, including some engineers from the United States Geological Survey.

The subject for the evening was "Electricity in Mines," an original paper, presented by Geo. R. Wood, consulting electrical engineer, of Pittsburg, Pa., who took up the general subject and gave a very complete outline of the application of electricity to coal mining. The lecture was profusely illustrated by lantern slides.

The subject was discussed by F. L. Sessions, of Columbus, Ohio, chief engineer of the Jeffries Manufacturing Company; W. A. Thomas, T. H. Schoepf, J. N. Mahoney and F. C. Albrecht, of the Westinghouse Electric and Manufacturing Company; H. L. Brown, of the General Electric Company, and H. W. Fisher, of the Standard Underground Cable Company.

The subject for the next meeting will be "Some Experiences in the Application of Gas Power in the Operation of Sixty-Cycle Industrial Plants, with Special Reference to the Plant of the Union Switch and Signal Company," an original paper, by J. R. Bibbins, of the Westinghouse Machine Company.

Features of Municipal Lighting in Chicago—Past and Present.

At the meeting of the Chicago Electric Club, held on November 11, William Carroll, City Electrician of Chicago, delivered an interesting address on the features of municipal lighting in Chicago.

For the purpose of making comparisons, early in the year, Mr. Carroll obtained some information about the street lighting of a few American cities, and found at that time, that—

	Arc Lamps.
Chicago had	8,822
Greater New York	14,756
Philadelphia	12,018
Cincinnati	5,651
Boston	3,800
St. Louis	1,150

The annual cost of lighting was:

Chicago	$1,031,542
New York	2,648,546
Philadelphia	1,621,049
Cincinnati	411,704
Boston	805,835
St. Louis	615,960

The costs include gas and gasoline as well as electric.

The cost per square mile was the lowest in Chicago, and the highest in Boston. The cost per candlepower was the lowest in Cincinnati, with Chicago a close second, and St. Louis the highest.

Only two of these cities, New York and Philadelphia, had a greater estimated candlepower than Chicago, and only one, Greater New York, a greater area to be lighted. All maintained gas and gasoline lamps in addition to the electric arcs, New York having over 43,000 gas and 4,300 gasoline lamps. Chicago is behind Boston, Philadelphia and Cincinnati in the candlepower per square mile, but ahead of New York and St. Louis.

This is not a very good showing for Chicago, but not as bad as it might be, but such as it is the bad features exist through no fault of either Mr. Carroll's predecessors or himself. They were and are willing to improve conditions, but have never been able to get sufficient funds to make a complete job. This is an old cry, but a true one. They have been going along, a little at a time, trying to build up an electric-lighting system out of the crumbs dropped from the proceeds of general taxation, when it should have been built at once, he says, out of the proceeds of a bond issue.

The city's electric street-lighting plant was started in the year 1887. At the end of that year there were 104 lamps in service. The power equipment consisted of one 125-horsepower engine, located in the basement of a fire-engine house at the corner of Clinton and Washington streets. In the following year a 300-horsepower engine was added, it being located in a fire-engine house on Jefferson Street, near Van Buren. At the end of the year 1888, there were 279 lamps in service. In the year 1889, a power house was erected on Throop Street, near Van Buren, and the two earlier power stations were abandoned. In the year 1893, the city passed an ordinance requiring that all electric-light extensions must be made by special assessments. This put up to the property owners along each street the proposition that if they wanted electric lights, they must pay for them out of their own pockets. This action appears to have put a damper on the electric-light extensions, as in 1893 there were only ten lamps placed, in 1894 none, and in 1895, eight.

In 1896, the city placed a conduit system and erected lamps on Ogden Avenue, from Madison Street to Twelfth, by special assessment. Some of the property owners along the street refused to pay the assessment, and carried the case into court, where the ordinance was declared unconstitutional, and subsequently disappeared from the Municipal Code.

At the end of the year 1904, seventeen years after the first start was made, there were 5,107 lamps in service. During the next two years 1,909 lamps were placed in service, and in the year 1907, 1,190 lamps were added, there being at the close of that year 8,206 lamps in service.

Up to date in the present year, the city has installed approximately 1,000 additional arc lamps, and the work under way will provide for the addition of 3,000 more; 5,190 lamps in two years of the present administration, more than were added during the first seventeen years of operation.

At the present time there are 9,165 arc lamps operated from the city's circuits. The city is renting 674 lamps from the Commonwealth Edison Company. The rented lamps are located, for the most part, in the southern part of the city, where the city circuits have not been extended.

The cost to the city of Chicago for street lights during the year 1895 was, in round numbers, $1,098,000, and the estimated candlepower 3,964,000. The cost for the year 1907 was $1,031,542 and the estimated candlepower 18,233,000, there being in the last thirteen years a slight reduction in the total cost of street lighting and an increase of about 460 per cent in candlepower.

At the present time the city's streets are lighted by 9,165 municipally-operated arc lamps, 674 rented arc lamps, 10,523 open-flame gas lamps, 12,102 mantle gas lamps, and 7,000 gasoline lamps. At the end of the year we expect to have approximately 12,700 arc lamps in service, including the rented lamps and not including the lights maintained and operated by the Park systems.

The power for the operation of all the city lights is obtained from the Sanitary District of Chicago, the energy being delivered to the city at the District's terminal station on Western Avenue, near Thirty-first Street.

At three of the old stations the city is operating the old direct-current dynamos by synchronous motors, the motors being direct coupled to line shafting and the line shafting belted to the dynamos. From these stations the city is operating approximately 5,000 direct-current open-arc lamps. The steam plants are being held in reserve.

About 4,100 series enclosed, alternating-current arc lamps are being operated through constant-current transformers and automatic regulators. For future extensions to the arc-lighting system, a series of transformer substations have been planned, having a capacity of 1,350 lights each. In each substation there will be three 250-kilovolt-ampere, single-phase transformers, stepping down from 11,500 to 4,200 volts. There will be twenty-seven regulators to operate the same number of fifty-light circuits.

The buildings are to be of brick and reinforced concrete throughout, and absolutely fireproof. Two of these buildings are in process of construction at the present time. One is located on Wood Street, near Nineteenth, and the other on Wentworth Avenue, between Forty-seventh and Forty-eighth. The outside construction work, building of conduits, pulling cables, setting poles, stringing wires and hanging lamps, is nearing completion. The station at Wood and Nineteenth streets will operate all the lamps in the territory bounded by Twelfth Street on the north, the Chicago River on the south and east, and Rockwell Street on the west. From the Wentworth Avenue station there will be operated all the lamps located in the district bounded on the north by Thirty-ninth Street, on the east by Grand Boulevard, on the south by Garfield Boulevard, and on the west by Halsted Street, the stations being located nearly in the center of the districts lighted.

The circuits will be comparatively short, the longest one containing about four and one-half miles of wire. Some of the older city circuits contained twenty-eight miles of wire.

A similar station, although not so pretentious or expensive, located in the rear of a city bath house on Emerald Avenue near Thirty-fourth Street, was put in operation early in the year. From this station the city is operating 936 lamps. The circuits are all aerial, with iron poles and No. 6 weatherproof, copper wire.

The cost of the completed equipment, building, transformers, regulators, lamps, switchboards, circuits, conduits, cables, transmission lines, etc., was \$107,582—nearly \$115 per lamp. The lamps operated from the station will cost approximately \$38 per lamp per year, including investment charges. This may appear low, but there are no production charges except the \$15 per horsepower-year paid the Drainage trustees, and the distribution costs are low, on account of the new and short-circuits, iron poles, etc. The labor is practically confined to lamp trimmers, patrolmen and line repairmen. The total fixed charges for this station are estimated at \$11,508.37 per year, making the investment charges about \$12.30 per lamp.

In the report on municipal street lighting, recently submitted to the Mayor and City Council by B. J. Arnold and Arthur Young, there is given an estimate of the cost per lamp, with complete alternating-current equipment, and steam plants discarded, of \$42.17. It has been estimated that it will take altogether 29,000 arc lamps to properly light the city's streets and alleys. With 12,700 in service at the end of the year, approximately 700 of which will be rented lights, there would remain 17,000 arc lamps to be installed to complete the municipal lighting of the streets and alleys with arc lamps. Assuming that the installation will cost \$115 per lamp, there would be a total required of \$1,955,000, to which must be added the cost of replacing the existing 5,000 open-arc lamps and equipment, which may be roughly estimated at \$70 per lamp, including buildings, transformers, regulators and lamps; so that there is required for the completion of the system approximately \$2,305,000.

Assuming that the completed equipment with alternating-current lamps can be operated at \$40 per lamp, including investment charges, there is an annual cost of \$1,160,000, not much more than the present cost of the street lighting.

The problem now before the city officials is how to raise the \$2,305,000, together with money required for other permanent improvements, such as building the new City Hall, building schoolhouses, bridges, police stations, fire-engine houses and other public works, which may be considered as permanent improvements that will benefit posterity, and the cost of which posterity should help to pay.

Annual Report of the Commonwealth Edison Company.

The annual report of the Commonwealth Edison Company for the fiscal year ended September 30, 1908, was issued on November 9. The net earnings, applicable to dividends, were equal to 6.19 per cent on the \$30,000,000 of capital stock.

BUSINESS SUMMARY.

Gross income from electric current and merchandise sales...	\$ 9,500,907
Operating, repairs, and renewals, depreciation, taxes and general expense	6,374,578
Net income from all sources..	\$ 3,126,329

CHARGES AGAINST INCOME.

Interest on bonds and debentures	\$ 1,032,625
Depreciation reserve (Under the terms of the mortgages made by the Chicago Edison Company and the Commonwealth Electric Company).	236,000
Dividends paid	1,372,035
	\$ 2,640,661
Balance	\$ 485,668

ASSETS.

Plants, real estate, etc.	\$51,657,050
Unfinished plant investment	318,498
Open accounts	308,598
Material	520,199
Accounts and bills receivable	1,193,933
Cash	1,567,433
Total	\$55,565,706

LIABILITIES.

Capital stock		\$30,000,000
Bonds and debentures	\$21,243,000	
Unsold	500,000	
Sold and outstanding		20,743,000
Real estate mortgages		220,000
Depreciation reserve		1,794,500
Accounts payable		523,768
Municipal compensation		102,477
Taxes accrued		475,000
Bond interest accrued		264,139
Surplus account		1,442,820
Total		\$55,565,706

In the annual report, President Samuel Insull calls attention to the following facts:

"In opening the books of account of this company your directors thought it advisable to have made a detailed inventory and valuation of the property and business acquired through the consolidation rather than start with the book values of the constituent companies.

"The making of this inventory and valuation was intrusted to H. M. Byllesby & Co., whose exhaustive report, after an examination extending over a period of six months, has been taken as the basis for the initial-investment entries in the company's books."

The Commonwealth Edison Company came into legal existence and began business on September 17, 1907, through the consolidation of the Chicago Edison Company and the Commonwealth Electric Company, and the net earnings for the period from that date to September 30, 1907, are, for convenience, included in the surplus brought down on September 30, 1907.

The company's connected business, exclusive of electrical energy applied to other public-service corporations, amounted to the equivalent of 4,137,650 standard sixteen-candlepower lamps on September 30, 1908.

The company is also supplying electrical energy amounting to approximately 75,000 horsepower under long-time contracts, running from five to ten years, to street railways and other public-service corporations which have found it to their interest to purchase power.

Electrical Trades Association of Chicago.

The thirteenth annual meeting of the Electrical Trades Association of Chicago will be held in the new banquet hall of the Chicago Athletic Club, at 6:30 p. m., Friday, December 11. The business meeting will be in charge of William A. Browne, president, when reports of officers will be received, and other business that may properly come before the meeting enacted, followed by the election of officers.

The entertainment features will include speeches by B. E. Sunny, president of the Chicago Telephone Company, formerly Chicago manager of the General Electric Company; His Honor William H. McSurely, judge of the Superior Court; His Honor Fred Fake, judge of the Municipal Court of Chicago; the Hon. Charles E. Kremer, of the Chicago bar, and two members of the association, who will speak on association matters from the manufacturer's and jobber's standpoints. Thomas I. Stacey, of the Electric Appliance Company, will be toastmaster. Instrumental and vocal music will be rendered.

Western Society of Engineers.

On November 13 the Electrical Section of the Western Society of Engineers held a meeting in the society's rooms in the Monadnock Block, Chicago, to listen to an illustrated talk on "Recent Developments in Artificial Illuminating Engineering," by W. D'A. Ryan, of Lynn, Mass., illuminationg engineer for the General Electric Company.

In a short preliminary paper Mr. Ryan analyzed the work of the illuminating engineer, and pointed out some of the features discovered in recent illuminating problems. The designing engineer must take account of all factors bearing on his problem, both utilitarian and artistic. These factors require different consideration in different cases. In some cases high efficiency is of prime importance. In other cases the artistic effect is of chief value. Considerable attention has been given recently to the lighting of large interiors, particularly department stores, railway depots and large assembly rooms. The tendency is to do away with exposed lights, and such sources will gradually be banished as advance is made in illuminating standards. Where a perfectly white light is desired, such as in the "white" rooms of department stores, the tungsten lamp has given good results, but these are not to be classed with the success that can be attained in perfect color matching when arc lamps with diffusing globes are used. The requisites for this service are both whiteness and high intensity of illumination. The latter should approximate about two watts per square foot of floor surface. The tungsten lamp has achieved remarkable results in recent illuminating work and bids fair to take the place of even the arc lamp for many kinds of lighting.

After this Mr. Ryan showed scores of lantern slides illustrating recent advances in light sources and some good installations. He described the particular points of each type illustrated, and pointed out many interesting features in connection therewith. First, there were shown a large number of photometric curves of tungsten lamps as modified by the various forms of reflectors, shades, frosting, etc. Quite a number of views of pendent tungstoliers were shown with and without reflecting shades and varying from plain to very ornate designs comprising rich metal work and art glass. A number of chandeliers were shown ranging from simple designs to one for church lighting that was valued at $3,400.

Arc lamps with spherical enclosing globes of a large number of types were shown. Also one type having a parabolic reflector directly above the arc. This lamp is a new design and is in a class between the miniature and enclosed types. Its efficiency is said to be one watt per lower hemispherical candlepower. This lamp was particularly designed to have a perfect white light. The tungsten lamp is not nearly as white a source and, therefore, not so good for perfect color matching; however, in nine cases out of ten, Mr. Ryan said, the tungsten lamp gives more pleasing effects in the display of goods.

A variety of ceiling bowls with various types of globes and diffusers were shown. These were particularly adapted for use with tungsten lamps. An installation of this kind designed for the galleries of the Philadelphia Art Club was shown with a continuous row of these diffusers in the form of a large rectangle, which distributed the light very uniformly over the walls and left the center of the room in a subdued light.

A view of the New York Post Office was shown, in which the lighting is entirely by projecting arc diffusers. These Mr. Ryan does not regard as very pleasing in appearance, but very effective in light distribution.

The Washington Union Depot illuminating installation was shown in a number of views, particularly of the famous waiting room, which is one of the best examples of indirect lighting now in existence. Details of the lighting equipment in the coves were shown. There were also views in other waiting rooms, of the concourse and of the exterior. The Schenectady Depot was illustrated also.

The portable luximeter designed by Mr. Ryan was shown and briefly described. It is entirely self-contained, being equipped with all the instruments necessary and made up in a very compact form. It is intended for rapid and accurate determinations of illumination from zero to twelve-foot-candle intensities.

A number of views of a large machine shop showing the lighting as carried out by different systems were displayed, also a striking view of the Singer Tower in New York, which was the first building illuminated with projectors.

The lighting of Niagara Falls with several batteries of projectors was illustrated with a large number of very good views and described in considerable detail.

At the conclusion of Mr. Ryan's interesting talk the discussion was opened by James Lyman, who asked about the standard used in the luximeter. A standardized tungsten lamp is used for this purpose, said Mr. Ryan, as he gave further details about the use of the instrument.

A question by Chairman D. W. Roper elicited a reply that about 500 horsepower is used in the Niagara Falls illumination. This power is derived from the electrical plants at the falls. Prof. E. H. Freeman asked about the new white arc lamp that had been shown. Mr. Ryan described its construction further and showed how the use of small carbons increased the efficiency a great deal.

Mr. Lyman asked whether the tungsten lamp is going to reduce the use of arc lamps for interior illumination. To this Mr. Ryan replied that for interior lighting the arc lamp is now practically dead, or rather that it is fast being substituted and is passing out as steadily as the old open arc lamps. For some purposes, however, such as for instance for the lighting of white rooms, as he had already said, the arc lamp will undoubtedly hold its own. Mr. Roper remarked that since the introduction of the tungsten lamps there has been practically no new installation of arc lamps for interior lighting in the experience of his company.

P. Junkersfeld wished to know the watt consumption per square foot in the large waiting room of the Washington Depot. This, Mr. Ryan said, was arranged so that varying intensities of illumination using one, two or three watts per square foot can be used. He also showed by simple test diagrams when indirect cove lighting can be made very efficient and why, when certain features are disregarded, the lighting can be made very inefficient. With a consumption of three watts per square foot in this particular installation they claim an illumination of two foot-candles.

J. R. Cravath declared that indirect lighting has come to the front since efficient illuminants had been produced. A great advance has been made in producing light efficiently and equally great advance in utilizing the light produced. In general, he thinks, that it is highly desirable to confine the light more to the useful plane, and, therefore, to use reflectors that concentrate the light downward on the working plane without wasting much for side walls. This should hold true even for the lighting of fairly large spaces.

Mr. Ryan concluded the discussion by asserting that wide reflection is best for large interiors because it gives a much more uniform distribution. In fact, if such a thing was feasible, he would prefer to use the reflector giving as wide a distribution as possible. He showed that in lighting of department stores, for instance, where one source was installed per day a wide distribution of the light would not cause an appreciable amount of it to be wasted on side walls. Speaking of indirect lighting, he showed that an intensity of only half as much as with exposed lighting may give as good or even better results because the eye is better adapted to diffused light. Indirect lighting, however, may be carried too far since it produces a rather flat effect, such as we notice on cloudy days. Therefore, he would be in favor of having with the indirect lighting just enough direct lighting to produce a noticeable shadow in one direction so as to give tone to the general illumination effect.

National Sales Managers' Association.

About three weeks ago a half-dozen sales managers met at the Automobile Club, in Chicago, and formed a temporary organization, with C. A. S. Howlett, of the Western Electric Company, as chairman. A meeting was held on November 5, at the Great Northern Hotel, with about sixty-five present, and the National Sales Managers' Association was formed. H. H. Cushman, of L. A. Becker Company, Chicago, was elected president, and John T. Webber, of the Wabash Cabinet Company, Chicago, was elected secretary. Each of the sixty-five men present filed application for membership, and there are now four electrical men members of the organization, with about 100 others who have filed applications, representing some seventy-five different kinds of business. The plans include meeting every Thursday noon for lunch, at which time there will be an address by some prominent member of a sales organization. On November 12 the meeting was addressed by the sales manager of the Burroughs Adding Machine Company.

READY REFERENCES IN CALCULATING GENERAL ILLUMINATION.

BY W. B. BONHAM.

In designing the illumination of a room the use of the following table will be found convenient in determining the total candlepower necessary to produce a predetermined intensity:

Class of Service.	Ft. Candles.	Constant Dark.	Constant Walls.	Constant Light
Reading	2.0	0.50	....	0.40
Theaters	2.0	0.50	....	0.40
Churches	3.5	0.80	....	0.70
General store...	3.5	0.80	....	0.70
Desk illumination	3.5	0.90	....	0.70
Bookkeeping ..	4.0	0.95	....	0.80
Clothing	5.5	1.30	....	1.10
Drafting and engraving	7.0	1.70	....	1.40
Window lighting.	10.0	....	2.50	....

This table is to be used only where the light units are equipped with good reflectors.

The operation of this table gives the total candlepower, regardless of the size or type of light unit. In order to produce a uniform distribution of this light some attention must be given to the location of the units. This will be determined by the design of the rooms. As a general proposition, the lower the ceiling the greater will be the number of units necessary to produce an even distribution of light. The following formula is suggested:

$$A \times C = \text{total candlepower},$$

where A = area of floor space in square feet, and C is a constant to be found in the table opposite the class of service which is being considered, choice of the constant depending on the color of the walls in each case. The total candlepower divided by the number of units or clusters to be used gives the candlepower per unit or cluster, or the total candlepower divided by the candlepower of the unit or cluster gives the number of units or clusters necessary.

Example.—A room 70 feet by 120 feet, with light walls, is to be lighted to give good reading illumination. Referring to table (two foot-candles are required); The constant for light walls, 0.40; area equals 70 feet by 120 feet, 8,400 square feet. 8,400 $\times$ 0.40 equals 3,360 candles. Twelve units (three rows of four units each) have been decided upon; 3,360 divided by 12 equals 280 candles per unit or cluster.

If a unit containing five sixty-watt tungsten lamps had been decided upon, $5 \times 48 = 240$ candles. Then divide 3,360 by 240; equals 14 units.

Total candlepower multiplied by efficiency of lamps (watts-per-candlepower) equals total watts consumed.

If tungsten lamps are used multiply by 1.25; Gem, 2.5, etc.

The Chicago Electric Club.

At the noon-day meeting of the Chicago Electric Club on November 18, Thomas I. Stacey, secretary of the Electric Appliance Company, made an address on "Chicago, the Great Central Market." Mr. Stacey described the organization of the Chicago Association of Commerce, which was the outgrowth of the old Association of Merchants and Travelers. The present association is indebted for its organization, in large measure, to J. B. Compton, who initiated the movement in 1904. The organization has about 3,000 members. The committees include the Chicago River Improvement Committee, the Civic Improvement Committee, the Freight Traffic Committee, the Foreign Trade Committee, the Public Service Committee, the Street Traffic Committee, and the Ways and Means Committee.

To the Street Traffic Committee credit is due for the improvement in traffic conditions which is now being carried out in Chicago. The Freight Traffic Committee has secured improved service and better rates, particularly to that territory where the business interests of Chicago were not being favorably handled. One of the most important endeavors with which the association has been identified was the agitation in favor of the bond issue for building a deep waterway from the Lakes to the Gulf, giving Chicago access to the seaports of the world.

Chairman C. A. S. Howlett announced that at the next meeting of the club an address would be made by Frederic P. Vose on "Contracts."

W. P. Crockett announced that George Searing, one of the charter members of the club, was seriously ill, and it was unanimously voted to bear an expression of sympathy to Mrs. Searing.

New York Electrical Society.

The regular meeting of the New York Electrical Society will be held on November 24, at the Electrical Testing Laboratories, New York city. Dr. Clayton H. Sharp will present an address describing some of the recent developments in photometric methods and apparatus, and there will be a demonstration of the facilities available at the Testing Laboratories.

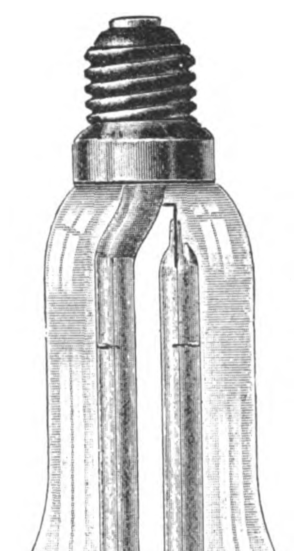
REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

THE WATERPOWER PLANTS OF SWITZERLAND.

The Swiss Electrotechnical Association publishes every year statistics of the electric stations in Switzerland, which are particularly interesting, on account of the fact that over fifty per cent of all the installations are exclusively waterpower plants, while another thirty-six per cent also exploit waterpower and have installed heat motors for reserve or as an addition. According to the statistics for the year 1906, there were 539 works and undertakings engaged in the distribution of electrical energy in Switzerland. Of these, 240 produced all their current by water turbines or heat motors, fifty obtained part of the current from other works, and 249 purchased all the current they distributed from third parties. The purely hydraulic plants supply about 59.8 per cent of the total performance of all the Swiss electric generating stations. Direct current is used by 185 of the power stations, single-phase alternating current by eighty-seven, two-phase current by eleven, and polyphase current by 150. For long-distance transmission direct current with parallel connection is used in ten instances (six per cent), direct current with series connection in seven (four per cent), single-phase alternating current in fifty-three (thirty-two per cent), two-phase current in seven (four per cent), and polyphase current in 143 instances (fifty-five per cent). For lighting, direct current is used in thirty per cent of the cases, single-phase current in thirty-two per cent, two-phase current in one per cent, and polyphase current in thirty-seven per cent of the cases. The tension used in long-distance transmission varies from 1,000 to 25,000 volts for alternating current, and from 5,000 to 25,000 volts for direct current. The periodicity of the current was fifty in seventy-two instances and forty in sixteen instances, the remaining stations using various frequencies. The current-consuming devices connected to all the stations and entitled to simultaneous operation corresponded to a capacity of 161,000 kilowatts. Statistics of the capital invested in the various installations are published this year for the first time. For installations producing their own current the average investment per kilowatt of capacity was 1,080 marks, 560 marks of this sum applying to the hydraulic and caloric parts, and 520 marks to the electrical part. For installations that only purchase and distribute current the average investment per kilowatt of capacity was 460 marks.—*Translated and abstracted from Elektrotechnischer Anzeiger (Berlin), October 18.*

A NEW CARBON-FILAMENT MERCURY-VAPOR LAMP.

A new lamp has recently been installed by Robert Hopfelt. This lamp is claimed to combine the advantages of the carbon



NEW CARBON-FILAMENT MERCURY-VAPOR LAMP.

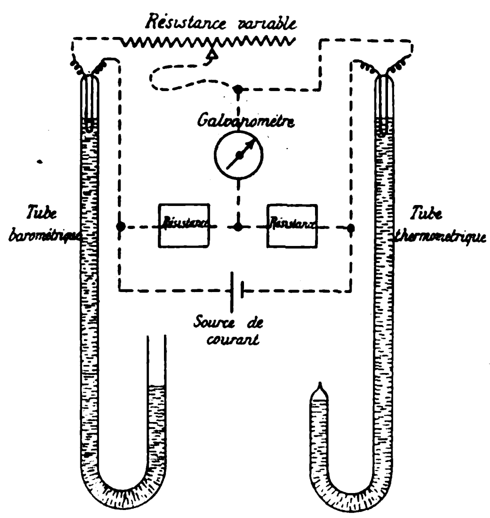
and mercury-vapor lamps, being insensitive to shock like the former and having the economy of the latter. The consumption of energy per candlepower is about sixty per cent less than that of ordinary carbon-filament lamps. The construction of the lamp is as follows: A carbon filament is fused into a U-shaped glass tube, which contains a drop of mercury and an indifferent gas in order to transmit the heat of the filament to the mercury. The U-shaped tube is then fused into a bulb, so that the completed lamp has the appearance of an ordinary incandescent lamp. When the lamp is started the filament at first glows with a consumption of about three watts per candlepower, like an ordinary lamp. As soon as sufficient mercury has been vaporized the light intensity increases more than twofold, so that the lamp consumes about 1.5 to 1.6 watts per candlepower. It requires about five minutes for the light to reach its full intensity, but as the lamps give light from the moment that current is turned on, they may be used for all purposes. The lamps are made for all the usual tensions, and their life under normal conditions is from 600 to 1,000 hours. The light is a pure white and contains no disagreeable green or blue rays.—*Translated and abstracted from Die Umschau (Frankfort a. M.), October 31.*

THE MANUFACTURE OF METALLIC LAMP-FILAMENTS.

Ing. B. Duschnitz, in this installment of a serial article on the various methods at present employed for manufacturing metallic lamp-filaments, describes the process employed by the Auer Gesellschaft, of Berlin. The firm uses an entirely new method of preparing hollow filaments of wolfram. The raw filaments, which are themselves neither hollow nor coated with a layer, consist of perfectly homogeneous material which must contain carbon; and, difficult as it may seem, they are transformed into hollow ones. The reduction methods that effect the transformation of these carbon-containing filaments into more or less pure wolfram filaments are already well known. If after one of these processes a carbon-containing wolfram filament is gradually heated and finally brought to white heat in an atmosphere which contains, besides hydrogen, or hydrogen and nitrogen, also minute traces of oxygen, then a wolfram filament is obtained which still contains a little carbon, but is not hollow. It was found that if the temperature of a raw filament through which current is flowing is rapidly raised long before the carbon has been chemically removed from it, a hollow filament is formed. This filament still contains considerable amounts of carbon which may be removed by any of the well-known methods, but the Auer Gesellschaft considers it of advantage to use the filaments directly in the lamps with rather high carbon contents. They are said to possess the advantage of requiring shorter lengths than solid filaments for equal voltages. A hollow filament is stated to be best obtained by placing a filament composed of about ninety-three per cent of wolfram and seven per cent of carbon in an atmosphere containing, besides hydrogen, or hydrogen and nitrogen, minute amounts of water vapor. The filament is then inserted in an electric circuit and the current intensity is allowed to increase rapidly by raising the tension, so that the filament is brought to white heat within a few seconds. The result is a filament which is hollow throughout its entire length. The diameter of the hollow space may be influenced by the rapidity with which the temperature is raised. If the filament is allowed to remain at a low temperature for a considerable length of time before it is brought to white heat, the hollow space will be smaller; it will be larger, if white heat is reached rapidly. The Auer Gesellschaft gives no explanation of this phenomenon, which might also be made use of for other technical purposes. With ordinary reduction methods the carbon particles contained in the raw filament come out from the filament substance only gradually with the progressive heating, and, when they arrive at the outside, are reduced to carbon oxide or carbon dioxide, and the filament substance shrinks together. On the other hand, when the carbon molecules are caused to vaporize by sudden heating, they have no time to escape to the outside, and consequently produce an interior pressure. This pressure, or expansion, of the carbon vapors forces the other filament substance radially outward, thus producing hollow interior spaces. It is possible that the resulting minute pores unite into communicating channels, the less resisting walls of the pores being expanded or broken through. As any escaping carbon is immediately absorbed by the surrounding reducing atmosphere, the filament shrinks together along its circumference; that is, the outside pores are filled by the softened metal immediately after becoming empty. The walls must then naturally become more resisting and impenetrable, and the carbon vapors circulating in the small communicating channels in the interior of the filament tend to increase these channels on account of their expansion at the high temperature of 2,000 degrees, so that after a little time a single longitudinal channel comes into existence. In support of the correctness of this explanation made by the author he cites the fact, that in such carbon-containing filaments hollow spaces may be clearly observed under the microscope, even if the process is interrupted before completion.—*Translated and abstracted from Elektrotechnischer Anzeiger (Berlin), October 15.*

AN ELECTRIC BAROMETER.

In this barometer, which is described by Robert Goldschmidt, the variations in the height of a mercury column resulting from the changes of atmospheric pressure are caused to modify the resistance of a filament of low specific conductivity in-



ELECTRIC BAROMETER.

serted in an electric circuit. A thin U-shaped carbon filament is fused into the closed end of a barometer tube and its terminals are connected to two binding posts on the outside of the tube. When the tube is filled with mercury, the curved part of the filament is more or less immersed in it, according to the atmospheric pressure to which the mercury column is subjected. The parallel branches of the filament traverse the vacuum of the barometer. The current passing through the two branches of the filament and the mercury meets with more or less resistance, accordingly as the mercury column is higher or lower. It is not sufficient, however, in order to obtain an indication of the changes in atmospheric pressure, to measure the variations of the total resistance of the carbon filament, as temperature changes also influence the level of the mercury column. This cause of error may be eliminated by using a second mercury column in a tube closed at both ends, in which the mercury level is influenced only by temperature changes of the surrounding medium. In this second tube, which operates as a thermometer, a carbon filament is arranged as in the first, and its resistance is modified by changes in the height of the mercury column. Thus, while the changes of resistance in the barometric tube correspond at the same time to variations of atmospheric pressure and temperature, the indications of the thermometric tube relate to temperature changes only. If the resistances composed of the two filaments are arranged in series like two branches of a Wheatstone bridge and compensated by resistances in the lower branch of the same bridge, a galvanometer connected in the usual manner across the bridge will remain at zero, when at an equal atmospheric pressure the temperature causes a change in the height of the mercury in both tubes at the same time. The relation of the compensating resistances will evidently vary according to the thickness of the filaments used in the tubes, their relative dimensions, and the changes of the mercury level produced by the same temperature variation in each tube. In order to indicate the variation of atmospheric pressure it is only necessary to insert in that branch of the bridge containing the thermometric filament, for instance, an adjustable resistance, such as a high-resistance wire mounted over a graduated scale, which, by means of a sliding contact, may be inserted more or less in the circuit. By regulating this resistance so that the galvanometer remains at zero, one adds to or takes from it exactly the same amount of resistance that has been added to or taken from the carbon filament in the barometric tube by variations of atmospheric pressure only. These variations are thus read on the graduated scale of the adjustable resistance. It is easy, by means of the arrangement described, to read variations of one-ten-thousandth of a millimeter in the height of the barometric mercury column. Curves obtained by means of this apparatus were found to correspond always with those at the Uccles Observatory.—*Translated and abstracted from Bulletin Mensual, Societe Belge d'Electriciens (Brussels), October.*

The grand total of excavation during the month of October on the Panama Canal was 3,224,638 cubic yards, the highest record for rainy-season excavation, based upon telephone reports from division engineers.

INDUSTRIAL SECTION

ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

REMOTE-CONTROL SWITCHES.

BY H. W. YOUNG.

In the construction of the modern building, the architect and engineer are often obliged to spend a great deal of time in determining the best method for the distribution and control of current for light and power service. This perplexity is occasioned by the increase in the use of electrical appliances and an attempt to control them by the usual methods, as the increase in size of conduit and conductor prohibits the location of the switch at the point most desirable for the control of the circuit.

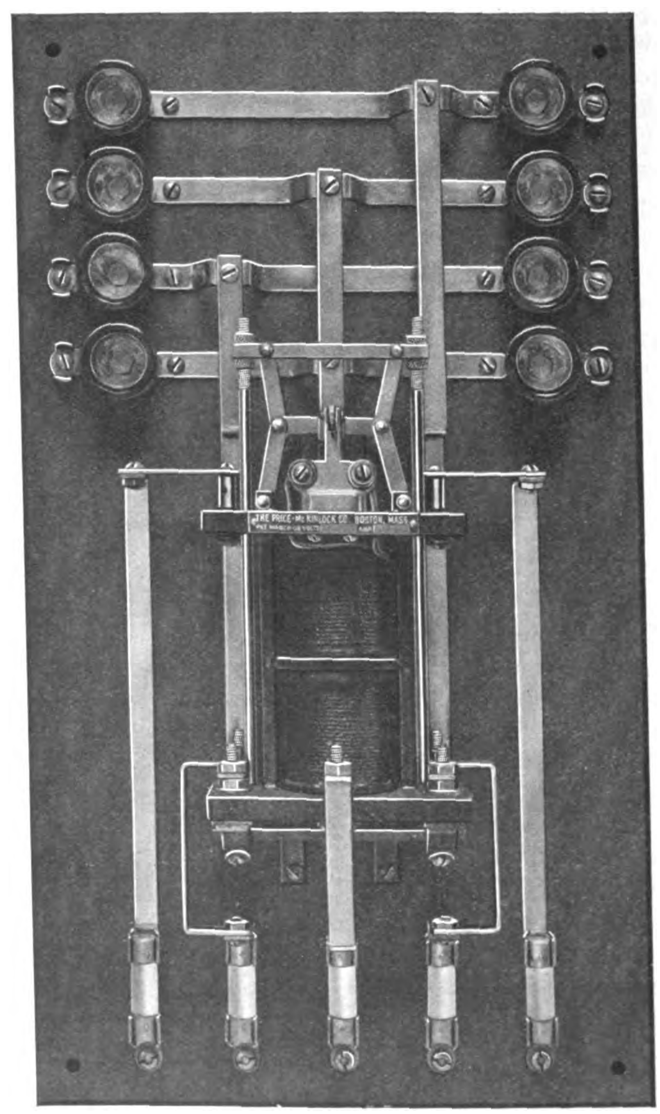
In handling circuits of greater capacity than can be controlled by standard flush switches, it has been customary to locate manual switches in the basements of buildings or in closets or corners not easy of access; and frequently the architect or contractor has been compelled to place switch panels where they marred the decorations of some room. In fact, it has seldom been possible to place these switches where they could be reached without inconvenience, though it is often necessary to use them several times a day for light or motor control.

To meet the conditions mentioned above, the remote-control switch illustrated herewith has been designed with a threefold object in view: First, to simplify the control of current; second, to enable anyone to control lights or motors from various points without making it necessary to bring the service wires to those points; third, to effect a direct saving in first cost of installation and consumption of current.

This switch is a magnetically operated device that can be furnished in practically any capacity, and controlled by momentary-contact switches, located at as many points as desired. It is built along the recognized lines of modern circuit-breaker practice, being provided with laminated contacts and steel toggle mechanism. It has a straight-line motion and cannot be left in a half-closed or half-open position.

It would be difficult to cite an instance of modern building construction in which electricity is to be used as an illuminant or a source of power where the value of remote-control switches would not be so apparent on the ground of either economy, convenience or safety as to warrant their use; and frequently the investigation would show their value to be many times their cost, in a direct saving of copper and conduit, with an indirect saving in current charges.

By the use of remote control it is possible to cut out lights or motors in any part of a building at any time, from any point where a momentary-contact flush push-button can be located. For example: If remote-control switches are located in the basement of a ten-story building which is lighted by electricity, it is possible to arrange on the desk of the superintendent, or anywhere in his office, which office could be located on any floor, a system of flush push-buttons controlling all the lights or any group of lights in the entire building. And it would only be necessary to run No. 14 wires direct to the office from the remote-control switches. Hence, with this switch there is no excuse for wasting current on account of the inconvenience of going to the ordinary switch panel-board. Other applications are obvious.



THE P-M REMOTE-CONTROL SWITCH.

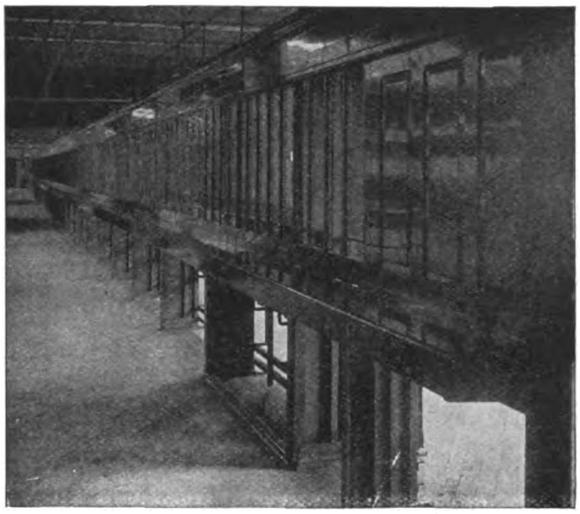
The system of remote control allows the electrical engineer to plan his wire-ways from service entrances to distributing panels without considering the switch outlets; so that the entire building may be supplied by one unbroken feed or its equivalent. This frequently makes it possible to effect a saving of fifty per cent in copper and conduit over the indirect method of wiring when a switch location is usually a long distance from the natural center of distribution.

In wiring buildings, the remote-control switches are located with reference only to their accessibility and the natural wiring centers; momentary-contact switches are located at the most convenient points from which it is desirable to control the lights, thus avoiding the necessity of either carrying the heavy mains to the switching point or installing the switch in an inconvenient location. These methods of wiring show in every case a saving of copper and conduit, and a convenience of use that reduces lighting charges and fire hazards to a minimum.

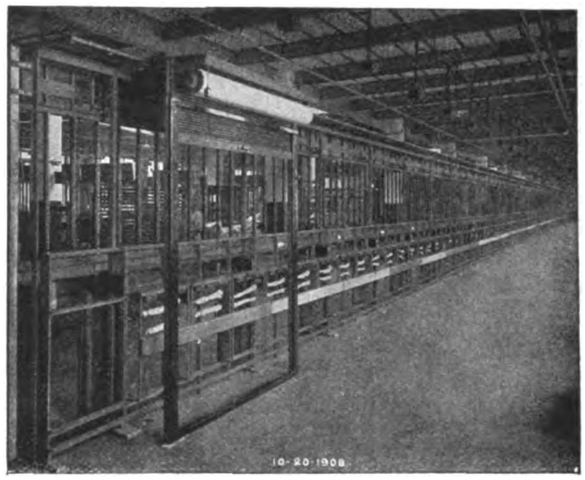
The complicated wiring systems in the modern theater may be greatly simplified by the use of remote-control switches, it being possible to so arrange a system of theater wiring as to greatly simplify the stage switchboard, giving better control of lights, and frequently making a considerable saving in the cost of wiring.

TELEPHONE SWITCHBOARD BUILDING IN RECORD-BREAKING TIME.

BY S. E. BROWN.



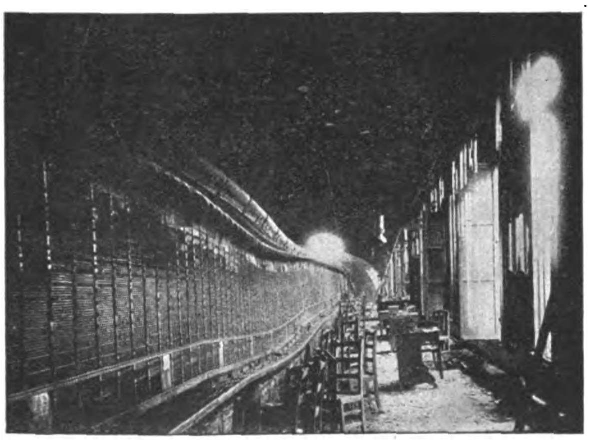
FRONT VIEW OF SECTION OF NEW WESTERN ELECTRIC PARIS TELEPHONE SWITCHBOARD.



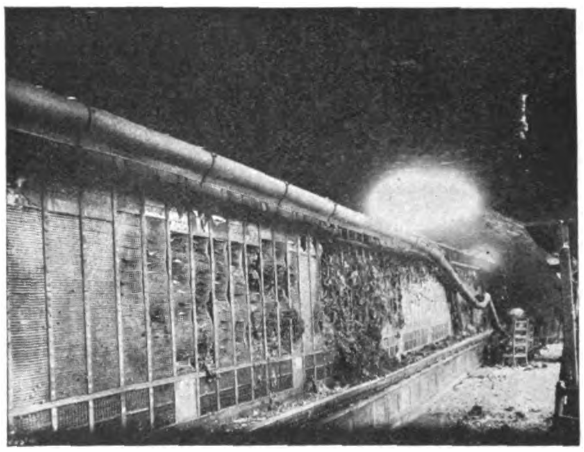
REAR VIEW OF WESTERN ELECTRIC PARIS TELEPHONE SWITCHBOARD LINED UP IN HAWTHORNE SHOPS PRIOR TO SHIPMENT.

Commercially speechless — such was practically the condition in which thousands of business men of Paris found themselves on the morning of September 21, 1908. Berlin, which the day before was at their elbows, now lay to the northward distant six hundred miles; London, only a moment's time away twelve hours before, was now across the sea; and the provinces of France which had lain within the shadow of the walls of the capitol now stretched from Alsace-Lorraine to the Pyrenees.

The burning of a single building in Paris—the great Central Telephone Exchange—was what isolated and paralyzed her commercially. The fire of a few hours' duration ate up $6,000,000 of property, took the business district out of a single structure and spread it over a wide area and pushed the city back in history more than twenty years.



PARIS MAIN OFFICE, 9,000-LINE BOARD, THIRD FLOOR, BURNED ON SEPTEMBER 20.



PARIS MAIN OFFICE, 10,000-LINE BOARD, FOURTH FLOOR, BURNED ON SEPTEMBER 20.

Rob any city of today of its telephone system and it goes back to where it stood before the telephone became a commercial necessity. But what makes the modern city helpless when its telephone equipment is destroyed is that it cannot go back. The reason for this is that the telephone made the modern city possible. Try to imagine New York's skyscraper district without the telephone! When deprived of its use, its value is appreciated.

Business for one day in Paris was carried on by means of what telegraph lines had not been ruined when the telephone building burned, by messenger service, by special conveyance, by each and every method possible that would give a greater speed than mail. The next day saw an emergency telephone equipment caring for crippled business as best it could. Meanwhile hurried conferences were being held by the Paris telephone managers with the Paris representatives of an American manufacturing company relative to an equipment to take the place of that destroyed. For emergency equipments at best are but first aids to the wounded and are to be put aside as speedily as possible.

The building of equipment for a telephone exchange the size of the one destroyed requires time, and the people of Paris were clamoring for telephone service. This explains why the managers of the Paris Telephone Company immediately after the fire took their problem up with the largest manufacturers of telephone apparatus in the world. Speed was the controlling factor; speed and quality. So they turned to a company that held the record for both.

The proposition put up to the Paris house of the Western Electric Company was a staggering one, but the Paris house had resources. They themselves had enormous facilities and back of them was the parent house in New York city which in turn was backed by the company's Hawthorne plant just outside the city of Chicago. This last-named plant is the largest telephone manufacturing plant in the world and for it rush orders hold no terrors. When fire eliminated the telephone plant in Rio de Janeiro the cable had wildly called for apparatus. Hawthorne met the demand. Then early in the year Tokyo had called on Hawthorne to build material to take the place of a large shipment for Japan which had been lost when the S. S. Holenfels was destroyed by fire. This work was done in less time than Tokyo demanded.

So when the request from Paris was telegraphed to Hawthorne the men in charge of the telephone manufacture figured coolly and swiftly. They knew what they had done before could be done again. September 22 Paris had the cabled reply that Hawthorne could furnish its part of the equipment complete in less than thirty days.

A diversion was created on September 24 by Paris asking for switchboard cable; a request which terminated a few days later in an order for 135,000 feet. The Western Electric Company, however, had the full amount of the size desired in stock at Hawthorne. Hawthorne was ordered to ship. But shipping cable by steamer differs from shipment by rail. The cable must be fully protected from salt water. Nevertheless, the twenty-five miles of cable was unwound from reels, the ends paraffined, cable rewound on reels, packed in waterproof cases and placed on cars in less than two days after receiving the order.

The most interesting fact brought out by the order, however, was not what the company did but what it could do. The Paris order for cable, as before stated, was made up from stock. The Hawthorne plant offered to turn out twice that amount weekly from raw material.

Meanwhile, the superintendent of the switchboard department at Hawthorne had been having more than a cable order to think about. On September 29 the New York house telephoned to begin work on a switchboard and cheerily informed him that the Paris house had agreed to have the entire installation completed in sixty days, and that a $600 daily penalty was attached to the contract. The information about the switchboard wasn't quite so indefinite as that, but it was pretty hazy. It was all the information New York could give, however, and all the Paris house could furnish, so the man at Hawthorne went as far as he possibly dared on his meager instructions, meanwhile wondering about the sixty days. He clearly understood about the $600 per day.

October 3 brought information which was definite. Already a large amount of material had been lined up and the moment the decisive word from Paris came, men trained to the minute in switchboard building began their tasks. In a trifle over three weeks after a definite order had been given by the managers of the telephone exchange in Paris, the finished switchboard stood at Hawthorne ready for chipment.

Meanwhile the New York agent had not been idle. The result of his efforts showed that express train speed in manufacture is only one of many ways of beating penalty time to the tape.

The same day that complete information was given Hawthorne a request was made for an estimate on the number of carloads and weight of the shipment. Reservation was made on a French Line steamer that sailed on October 29, and arrangements were made with railroads that special attention be given the shipment. It was. The six carloads of material came from Chicago to New York in about two days.

The shipment from Hawthorne together with a large amount of additional material which the New York house had manufactured was shipped to Paris on the French Line steamer La Provence, that sailed from New York on October 29. Thus, only a few days more than a month elapsed from the date the fire occurred in Paris until a completed switchboard from the United States was on the sea. A switchboard, by the way, which stands 180 feet long, requires ninety operators to operate and will accommodate more than 10,000 subscribers. While the back of this switchboard would appear as unintelligible to the layman as a page of Sanskrit, it may be of interest to know that it contains about a million soldered connections and 3,000 miles of wire. It is of some interest also to know that approximately 40,000 feet of lumber were used in packing the completed board, and that 10,000 square feet of paraffine paper was used in the cabling boxes alone.

A Big Shipment of Tungstoliers.

The accompanying illustration shows the way in which a big order for Tungstoliers was recently sent to one of the company's selling agents. This electric-lighting fixture has created a good deal of a stir throughout the entire field, and the

A BIG ORDER OF TUNGSTOLIERS.

company is booking orders which are far in excess of its expectations, although it arranged, in developing these light units, for a demand which marked a new record in supply and demand.

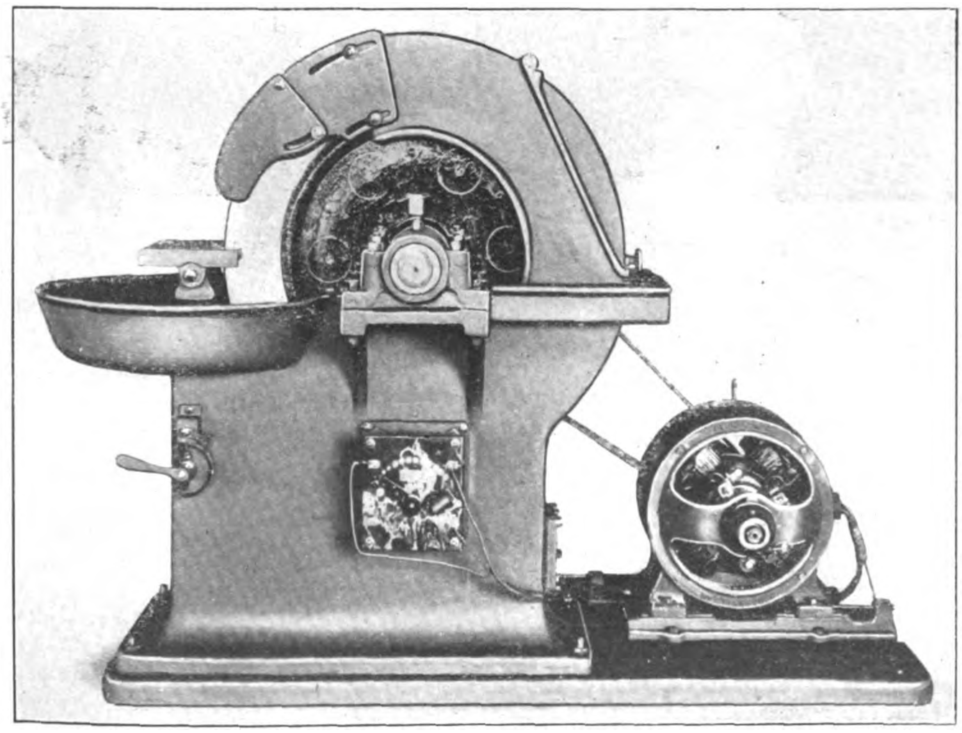
The Phelps Alloy.

Announcement is made of the discovery of the Phelps alloy by the Phelps Manufacturing Company, 54 State Street, Detroit, Mich. This metal fuses at 2,500 degrees Fahrenheit, is positively non-corrosive, and is said to be a reliable substitute for platinum for a great many purposes, such as contacts for electric bells, annunciators, telephones, spark-plugs, gasoline engines and automatic flashers. The cost of this alloy is said to be about one-third that of platinum, and from the tests which have been made it is expected that the metal will give entire satisfaction. Several large telephone companies are now using this material, and repeat orders are evidence of the satisfaction being experienced with it. The Phelps alloy is made in sheets, wires and rivets.

An Electrically Driven Tool Grinder.

Probably the first equipment in a machine shop to be driven by an individual electric motor in experimenting with electricity as a motive power is the tool grinder, because it combines so many of the various advantages of the electric drive. Tools are sharpened only at intervals and the load is fluctuating, permitting the outfit to be shut down between jobs and also taking advantage of any decrease in the demand for power. As a grinder has often to be located somewhat apart from the rest of the machinery, it becomes difficult to make the necessary belt connections where a mechanical transmission system is used. With a small motor supplying the power the grinder may be located at any point that convenience demands and the wires run to it without trouble.

The Safety Emery Wheel Company, of Springfield, Ohio, is supplying a thirty-six-inch by four-inch emery wheel, shown in the illustration, equipped with a standard Westinghouse direct-current, type S, four-horsepower motor. The motor runs at 1,175 revolutions per minute and drives the emery wheel at 450 revolutions per minute. The starting device for the motor is directly on the grinder, providing the most convenient method for bringing the wheel up to speed.



MOTOR-DRIVEN TOOL GRINDER.

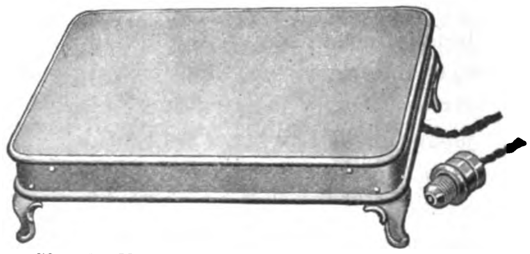
The illustration shows a constant-speed shunt motor, but the use of an adjustable-speed motor is recommended, as the speed may be increased to allow for wear of the emery wheel.

It will be noted that the motor is mounted well out of the way on the extended sub-base of the grinder, and therefore forms a very flexible outfit in that it may be moved as a unit. Two operators can work on the grinder at the same time, as a door provided in the hood in the rear allows grinding to be done there as well as in front. Water is prevented from splashing over the floor or the motor by the wide pan in front and the apron in the rear.

Electric Food Warmers.

Among articles for table service, the heated tray or platter made in plate is an old institution, and came into vogue many generations ago, its object being for keeping hot, ready for a second helping, the roasts and vegetables at dinner. These devices were made, some, with double bottoms for the reception of hot water between the two; others were made arranged with a spirit lamp for providing the heat. Because of the care in keeping these in order for service, they have never been used to anything like the extent they deserved.

The Simplex Electric Heating Company, Cambridge, Mass., has recently put on the market a line of electric food warmers, to take the place of these devices. Instead of applying the heat to a variety of platters or dishes, they provide a heated stand for use in the dining room, on which the food dishes may be set, and where they will be kept warm. They are in attractive design, in nickel or silver plate, having a top surface in dull-finish aluminum, which is not easily scratched or discolored, and the top, with the heater attached, is removable to facilitate the cleaning or polishing of the plated portions. The temperature is limited, so that there



SIMPLEX ELECTRIC FOOD WARMER.

is ample heat for the requirements, and yet not sufficient to endanger the choicest china in being injured. The current consumption is such that most of the sizes can be connected to lamp sockets, and the cost for operation is small.

These food warmers are made in a variety of sizes and designs, both oval and oblong, the top surface varying from 10 by 14 inches in the smaller sizes to 10 by 26 inches in the larger. They are furnished in moderate weights for domestic requirements, and in extra heavy weights for hotel use. The Simplex company reports an immediate demand for these goods both for hotels, restaurants and domestic use. They have supplied them in quantities to such New York hotels as the St. Regis, Hotel Astor, Cafe Martin, and others.

General Electric Orders.

The orders received by the General Electric Company for the third quarter of the year amounted to $10,397,117 and for the nine months of the year to $30,054,924. This compares with orders of $14,581,382 and of $49,677,500 received during the corresponding periods last year.

The orders received for the third quarter were smaller than in any year back to 1904, but they were larger than the orders for the third quarter of 1904 by over $2,000,000. The orders for the first nine months this year are larger by over $3,750,000 than the orders for the first nine months of 1904.

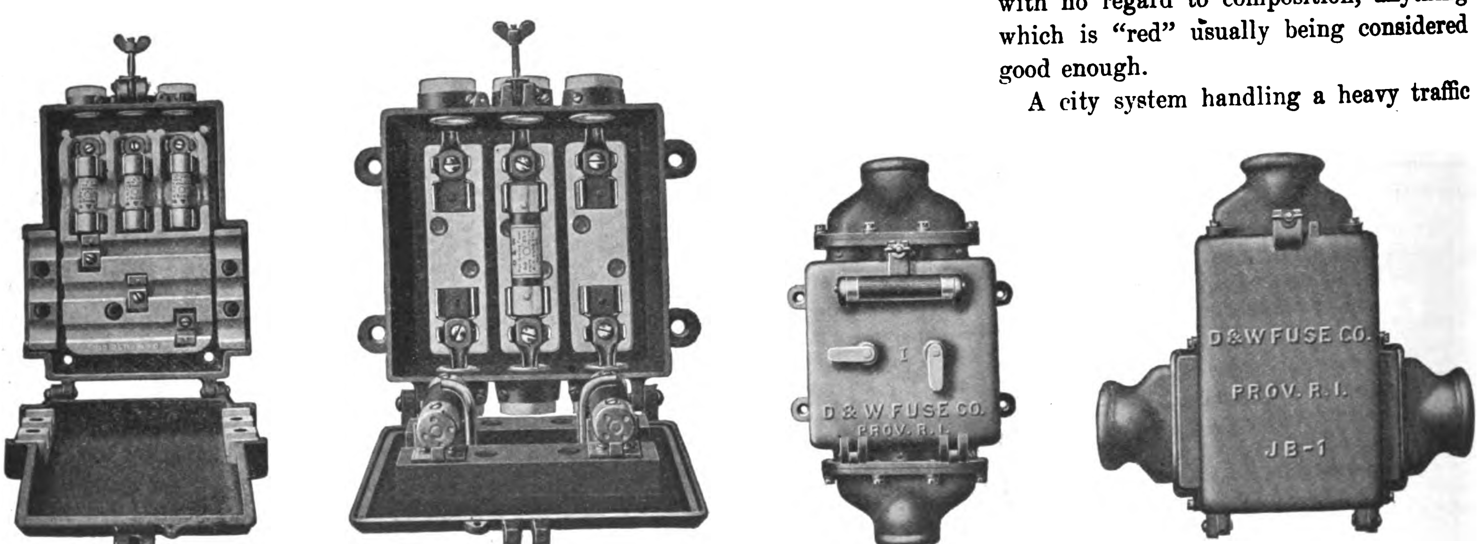
The sale of $350,000 worth of Alaska-Yukon-Pacific bonds appears to remove the last obstacle to the success of this enterprise, which is to open on June 1 next.

New Line of Service Switches and Cut-out and Branch Boxes.

The D & W Fuse Company, Providence, R. I., is placing upon the market its new service switches and boxes, which have very materially improved this line. In the casting of the iron, owing to operating its own foundry, the company is able to produce boxes of a much finer grade than it could purchase in the open market. Due to this higher-grade material, these boxes are lighter in weight than the former boxes and have a smooth surface, thereby taking a finer finish when japanned. These boxes are provided with rubber gaskets and removable porcelain bushings, through which the cable terminals may be readily passed. In the covers of the service switches are mounted fuse guides to positively align the fuses in order that the boxes may be readily closed with the fuses properly engaging in the cut-outs. There are also mounted in these covers withdrawal hooks which by one-quarter turn of the levers on the outside of the cover remove the fuses at will.

Owing to the usual practice of grounding the neutral on a three-wire direct-current system, the box is so designed that the neutral fuse remains permanently in the circuit, thus avoiding any possibility of accidents, due to the fuse being withdrawn. For polyphase circuits where all fuses should be removed, the box is provided with three hooks operated simultaneously by one lever. The fuse boxes are similar in construction to the service switches, but are intended for use only as cut-outs, and therefore no switch mechanism is provided for in the covers, the fuses being directly mounted in the boxes.

In addition to these cut-outs, the company has also brought out a line of branch boxes in which particular attention is called to the split bushings mounted in the cover, and boxes which permit of the necessary connections without any break in the wiring, thereby greatly reducing the cost of installation. For both of these types of boxes there have been designed a complete line of outlet hoods to be used in connection with the conduit system, covering every possible requirement of connection, namely, straight-away, right or left hand, and back and front. These hoods are firmly screwed to the boxes, fitted with rubber gaskets, if desired, and are interchangeable for any given type, being made to fit any size of conduit within the capacity of the box.



D & W FUSE COMPANY'S NEW LINE OF SERVICE SWITCHES AND CUT-OUT AND BRANCH BOXES.

Buying on Chemical Specifications.

Where dimensions, weight, finish and the like may be readily expressed in specifications, it is easy and natural to make them conditions upon which purchases shall be accepted. But where strength, chemical composition, durability and similar factors of ultimate efficiency are of importance, specification of these features is too often omitted.

In every industry some material is being bought on the basis of brand, reputation or even satisfactory experience in its use without the least idea that equal efficiency might be obtained at a lower price with a suitable material whose composition could be specified in advance by the chemist.

The purchasing agent of a large electric railway company was recently buying of a reputable supply house a metal for journal linings which gave good satisfaction. He was paying twenty cents a pound and, in view of the nature of the material, felt that the price was high. A sample was submitted to the Arthur D. Little Laboratory in Boston for analysis. Upon receipt of its report the purchasing agent sent out for bids upon a metal of the composition shown on analysis. A reliable concern at once offered such a metal at six cents per pound. As the amount of metal used in a year was large, the saving by having the same metal made to the formula was well worth obtaining.

Trolley ears are a class of material which the average electric road purchases with no regard to composition, anything which is "red" usually being considered good enough.

A city system handling a heavy traffic where delays cost money recently had considerable trouble by the frequent breaking of ears which they were purchasing of a reputable manufacturer. Two of the ears were sent to the laboratory named above for analysis. The report from this laboratory showed the following compositions:

	1	2
Copper	60.5	78.3
Zinc	38.5	16.5
Lead	0.4	4.4
Iron	0.1	0.2
Tin	...	0.5

The analyses show plainly the cause of the trouble: No. 1 is made of the ordinary 60-40 brass and is not strong enough for such work; No. 2 is evidently made from scrap composition and also fails to have the required strength.

This company is now buying under a strict specification. A sample from every shipment is analyzed and the number of breaks is very materially reduced.

Current Electrical News

CONTINENTAL EUROPE.

PARIS, NOVEMBER 7.—A type of petrol-electric motor car is in use upon one of the shorter railroad lines in Austro-Hungary, drawing trains made up of several trailers. The line is the Arad-Csanad local railroad, which connects a number of the large towns in the region, the most important of which is Szegedin. The present type of motor, adopted after a series of trials, consists of a long motor car of the usual form in which is placed a petrol motor and generator group, the latter furnishing current for the motors on the axles. At first the company adopted a thirty-horsepower car, which was designed especially for suburban use at slower speed. For the main lines it now uses a forty-horsepower car drawing two trailers, and more recently it ordered an eighty-horsepower car. The eighty-horsepower outfit contains a Westinghouse six-cylinder petrol motor, coupled direct to a six-pole generator. The car has two trucks, with a motor mounted upon each.

At Zürich recently I had occasion to examine the new plant which the municipality erected for the purpose of consuming household waste, which is laid out on an extensive scale. The waste is burned in a number of furnaces, using a strong air-draught to aid the combustion. The heat from the furnaces is supplied to a boiler which operates a steam turbine coupled to a generator. This furnishes all the current needed in the establishment for the lighting and for a number of motors, besides supplying several factories near by. The waste-consuming plant consists of a set of Horsfall furnaces. After the combustion there remains a certain amount of clinker and fine ash. The clinker is broken up and sifted, and may be used as gravel, while the ash serves as a fertilizer. In the dynamo room is erected a 150-kilowatt Brown-Boveri steam-turbine set, which furnishes three-phase current at 220 volts.

The ferryboat plying between Guilleboeuf and the opposite bank of the Seine, at a point near the channel coast where the river has a great width, is operated on the petrol-electric method, using a seventy-horsepower De Dion-Bouton petrol motor coupled to a 220-volt generator. This outfit is duplicated. The boat is a side-wheeler, the paddle-wheels being driven by two electric motors, which run at 540 revolutions per minute, the gear reduction enabling the wheels to revolve thirty times per minute. Ordinarily a single generator group is sufficient to supply all of the power needed, but in case the tides, which are strongly felt here, should make it necessary, the two groups can be coupled in parallel.

A hydro-electric plant of somewhat novel construction is located in the Rhone valley not far from Lake Leman. It utilizes the water of the celebrated Pissevache Fall, whose stream springs out of the side of the mountain and falls 220 feet into the valley, thus forming one of the most picturesque falls in the county. The electric plant is placed high up in the mountain side and lies above the mouth of the fall. It only uses the water in a gorge before it reaches the fall, and the water is then returned to the cascade in order that the latter will not be impaired. The turbine house is cut in the solid rock and is a chamber of elliptical section, containing the turbo-generator outfit. At present there are six principal groups installed. Two of these are used to furnish direct current at 800 volts for the Martigny-Chamonix railroad, while four of the machines supply 5,000-volt alternating current for use in a neighboring electric furnace plant. The remaining alternator also works at 5,000 volts, supplying current for lighting some of the towns in the vicinity. The water supply is taken at a point lying farther up the gorge, and in this way a head of water of 1,600 feet is obtained. The turbine plant lies at a height of at least 300 feet above the level of the valley. A. DE C.

GREAT BRITAIN.

LONDON, NOVEMBER 6.—There seems to be quite a craze at present among local authorities to go in for the trackless-trolley system, either instead of tramways, or in outlying districts, thus using this mode of traction as a feeder to the main tramway system. The Highways Committee of the London County Council, however, made a proposition this week to use the system in quite another direction. The Council is faced with the position of having its northern and southern tramway systems broken off, so to speak, by the river at Rotherhite and Blackwall by two tunnels which are incapable of holding a double line of fixed tramways. The Highways Committee, which realizes the advantages of linking up both the northern and the southern systems wherever possible, thought to overcome the difficulty by the use of trolley omnibuses in these two tunnels. How far such a policy was desirable from the point of view of the passengers, they having to make two changes in a very short distance, is another matter, but the County Council at its meeting on Tuesday vetoed the suggestion on the ground that sufficient information as to the capabilities of the system are not yet available.

Following the annual meeting of the Victoria Falls Power Company come some inquiries in Parliament as to the rights of the company to the concession for the use of the Falls water. It appears that this is given in an agreement between the British South Africa Company and the African Concessions Syndicate, which is the parent company of the Victoria Falls Power Company.

It is evident the Government intends that the London County Council shall secure control of the whole of the electric-supply arrangements of the metropolis in the future. Following the instruction to the committee which is now dealing with the bulk supply scheme to insert the name of the County Council as the purchasing authority, a similar instruction has been given with regard to the bills of the existing companies, which confer certain additional powers upon them. The question now arises what is to be done with the electrical undertakings of the London borough councils. If these are not also made purchasable by the Council, we shall have the anomalous position of the Council, when it purchases the bulk and the other companies, competing with the borough councils, the capital for whose undertakings the County Council has had to sanction and find. Presumably the committee will deal with this aspect of the case.

The Institution of Civil Engineers has just issued its list of awards for papers read during the past session, and I notice that the only paper dealing with an electrical subject which has been granted an award is that by W. Barclay Parsons on "The New York Rapid Transit Subway."

An experiment in street lighting is being carried out in Leeds, arc lamps and gas lamps being placed side by side for competitive purposes. G.

EASTERN CANADA.

OTTAWA, NOVEMBER 14.—The annual convention of the Canadian Street Railway Association, whose members include all the leading street railways of the Dominion, was in session here during the past week.

One of the most extensive industrial plants in Montreal is the Northern Electric and Manufacturing Company. It employs 1,300 persons, and its market is almost exclusively in Canada. This plant is equipped with the most modern machinery and will be operated entirely by electricity, the power being supplied by a 300-kilowatt Westinghouse-Parsons steam turbine.

It is a matter of note that Montreal consumes more electrically transmitted waterpower than any other city in the world. This power is drawn from three large generating stations located on the rivers St. Lawrence, Richelieu and St. Maurice, at distances ranging up to eighty-five miles from the central substation in the city of Montreal, while a fourth large hydroelectric plant, which derives its power from the Soulanges Canal, has just been completed. With this chain of electric plants, supported by steam stations at various points in the city, the reliability of electric supply in Montreal is assured beyond any doubt.

Canada is most fortunate in possessing as much available waterpower as any country in the world. Some idea of the supply of power that can be generated in the Dominion may be had from the fact that, it is estimated, the St. Lawrence River alone can supply over 10,000,000 horsepower. There is represented also over 1,000,000 horsepower in the falls and rapids within a radius of fifty miles from the city of Ottawa, and what is true of eastern Canada applies equally to the Lake Superior and western portions of the Dominion.

It is stated that private individuals in the town of Coaticook, Quebec, are contemplating the formation of a company and taking over the town's electric-light plant. As the town is now facing a serious problem, in the way of increased power, a proposition for purchase will probably receive favorable consideration of a majority of the rate payers.

During the week, the first unit of electric power, from the Soulanges Canal, was brought into the city of Montreal and distributed through the city over the wires of the Montreal Light, Heat and Power Company. Since purchasing the charter for the utilization of this power from M. P. Davis of Ottawa, the Montreal company has been at work on the development, which is now completed, and at a cost of $1,500,000 the company has secured a supply of 15,000 horsepower. The work included the construction of a canal connecting the Soulanges Canal, about thirty miles from Montreal, with the St. Lawrence River, a distance of about 2,800 feet. The new canal holds 75,000,000 gallons of water and is 268 feet wide from bank to bank, 232 feet at the water line, 160 feet at the bottom and eighteen feet deep. A forty-foot roadway connects the dam and the power house, and the latter is fireproof, being built of concrete, with iron and glass windows. The six gates, connecting the Soulanges Canal with the new cut, are operated either by hand or by electricity. As the Montreal Light, Heat and Power Company has, at present, contracts which call for the supply of 70,000 horsepower, and has only 65,000 horsepower available, the company has under consideration the construction of a steam plant to provide 10,000 horsepower additional. This steam plant will be completed unit by unit, but the whole will be in operation within the next two years. The disposition of the available power will then be as follows: Lachine, 15,000 horsepower; Chambly, 20,000 horsepower; Shawiniga, 20,000 horsepower, and Soulanges, 15,000 horsepower; total, 70,000 horsepower.

W.

WESTERN CANADA.

WINNIPEG, NOVEMBER 14.—The postal authorities at Edmonton, Alb., have approached the civic authorities with a view to having the new electric street railway system used for postal purposes. It is understood an agreement has been arrived at to this end and freight cars will also be operated as soon as possible.

At the meeting of the Canadian Street Railwaymen's Association held in Ottawa on November 12 it was decided to hold the next convention in Winnipeg.

The Canadian Northern Railway Telegraph Company has opened telegraph offices in the following places: Lavelle, Ont.; Lena, Myrtle, Vassar and Russell, Man., and Borden, Sask. It is understood this company will soon negotiate for connections with the States.

The incorporators of the Kootenay Telephones, Ltd., which has a capital of $200,000, and head office at Cranbrook, B. C., are announced to be: Dr. J. H. King, W. F. Gurd, James Ryan, V. Hyde Baker, A. Leitch and R. E. Beattie. The company has already secured the plant and lines of the Cranbrook Light, Heat & Telephone Company and has secured a franchise in Fernie, B. C., to construct a telephone system. The aims of the company are to construct long distance and local telephone systems throughout the Crows Nest Pass country and to connect with the system of the Alberta government, thus giving Winnipeg, connection with the Kootenays.

At Cannington Manor, Saskatchewan, a rural telephone company is being formed. Estimates show the system can be constructed for $35 per mile with one telephone to the mile. The telephone act of Saskatchewan provides for the formation of these rural companies and places the value of the shares at $25 apiece, no person being allowed to hold more than one share.

The ownership and operation of the street railway system at Port Arthur, Ont., is in a curious tangle. The system was built by Port Arthur in 1893 and extended through the sister city of Fort William. Until the present time Port Arthur has owned and operated this system, but recently some of the aldermen from both cities met in Toronto and arranged for the sale to Fort William of that portion of the system running in Fort William. No vote was put to the people and consequently when the time for handing over the portion of the line to Fort William arrived the Port Arthur commission refused to give it up to the joint commission which had been appointed to operate the system. The Ontario Railway and Municipal board was appealed to and issued instructions to the sheriff to seize the system and hand it over to the joint commission. An injunction prevented the sheriff from acting, and mass meetings, attended by virtually every ratepayer in Port Arthur, are being held to protest against the deal. The matter will come up in the courts in the near future, and petitions have been mailed to the Hon. J. M. Gibson, lieutenant-governor of Ontario, Sir James Whitney, premier of Ontario, and various other bodies of influence. At the present time two sets of officials are supposed to be drawing salaries for managing the system.

R.

IMPORTANT DEVELOPMENTS.

CLEVELAND TRACTION LINES PUT IN HANDS OF RECEIVERS—Judge Tayler of the Federal court has appointed Warren Bicknell and Frank A. Scott as joint receivers for the Municipal Traction Company and the Cleveland Railway Company. Each of the receivers will furnish a bond of $100,000. Warren Bicknell is president of the Havana Electric Company, which controls all the street railways in Havana, Cuba, and is identified with large numbers of electric traction companies in Ohio and other states. Frank A. Scott is secretary and treasurer of the Superior Savings and Trust Company of Cleveland. The receivers will take charge of the traction system at once, and will operate it under the direct supervision of the court. The rate of fare, it is said, will be as low as can be made consistent with good service.

AUTOMATIC TELEPHONE DILEMMA—Samuel McRoberts, president of the Illinois Tunnel Company, has appeared before the Chicago City Council committee on gas, oil and electric light in the interest of the petition of his company for an extension of two years in which to obtain the required 20,000 telephone subscribers. The franchise of the company provides that that number of telephones must be in operation by next February, or, according to an opinion given by Assistant Corporation Counsel Emil C. Wetten, the city can take over the telephone properties of the corporation, operating the system itself or disposing of the franchise to any other company, as it sees fit. At present the tunnel company has about 5,000 of the automatic telephones in operation. Mr. Roberts said his company could install these telephones before next February, "not in a sensible or businesslike way, but to preserve its rights if necessary." He declared that the company is not going to forfeit the franchise, as there is too much property involved.

GREAT FALLS POWER AND TOWNSITE COMPANY TO SPEND $5,000,000 ON POWER PLANT—John D. Ryan, who with associates has purchased the Great Falls Power and Townsite Company, announces that they are about to begin the expenditure of $5,000,000 in building dams and a power plant, and that the construction of a power transmission line, 165 miles long, will soon be begun. This line will run into Butte, Mont., and give power for the Butte mines. The company will also build a wire factory at Great Falls and make wire from Butte copper with which it will supply the entire copper wire market from the Missouri River to the Pacific Coast, and will operate plate-glass, carbide and cement factories in connection with the power company.

MONTREAL LIGHT, HEAT AND POWER—The Montreal Light, Heat and Power Company has made arrangements to secure 100,000 additional horsepower in the next two years. Besides securing power from the new Soulanger plant a new large steam plant will be secured.

BOSTON & NORTHERN AND OLD COLONY ROADS TO ISSUE NEW STOCK—The Massachusetts Railroad Commissioners have granted the petition of the Boston & Northern and Old Colony Street Railway Companies, Boston, Mass., for authority to issue $1,096,300 capital stock at 110. The new stock is six per cent preferred, and the distribution is $723,600 Boston & Northern, and $372,700 Old Colony. The proceeds will be used to pay off floating obligations of these companies, the amount of which, in hands of the public, is about $2,500,000.

TELEPHONE MERGER DECLARED OFF—The big telephone deal by which it was proposed to lease the property of the United States (or long-distance) Telephone Company, the Cuyahoga Telephone Company and the Columbus Citizens' Telephone Company to a holding company for 999 years, has been declared off. The negotiations to transfer the properties to the holding company had been going on for weeks and the directors of each company had recommended to the stockholders that the lease be made. Announcement that the proposed deal had failed was made by President Brailey, of the Cuyahoga Telephone Company, following a meeting of the directors.

ENGINEERING SOCIETIES.

TOLEDO SECTION, A. I. E. E.—The Toledo Section of the American Institute of Electrical Engineers held a meeting on November 6 to hear the reading of a paper on "The Westinghouse Nernst Lamp; the Value of Its High Efficiency and Improved Mechanical Construction to Modern Methods of Illumination," by A. E. Eustice. The paper was illustrated with about eighty lantern slides, showing various lamp units, their construction and characteristics, as well as commercial installations equipped with them.

STEVENS ENGINEERING SOCIETY—The Engineering Society of Stevens Institute of Technology, Hoboken, N. J., has published its programme of activities for the season of 1908-09. This includes general lectures, special lectures, inspection trips, and some information concerning the Engineering Society Employment Bureau. Lectures will be delivered by President Alexander C. Humphreys, Arthur G. Glasgow, Calvin W. Rice, W. J. Armstrong, Ferdinand Stark, G. L. Fowler, A. C. Triaca and Frederick K. Vreeland, in the general lecture course. Special lectures will be delivered by Prof. Louis A. Martin, Prof. Albert F. Ganz, Prof. Frank L. Sevenoak, Prof. John C. Ostrup, Prof. George V. Wendell, Prof. Francis J. Pond and Prof. Franklin de R. Furman.

DATES AHEAD.

National Society for the Promotion of Industrial Education. Annual meeting, Atlanta, Ga., November 19-21.

International Independent Telephone Association. Annual convention, Chicago, Ill., December 1-3.

American Society of Mechanical Engineers. Annual meeting, New York city, December 1-4.

American Roentgen Ray Society. Annual meeting, New York city, December 28-30.

Chicago Electrical Show. Coliseum, Chicago, Ill., January 16-30, 1909.

American Association for the Advancement of Science. Annual meeting, Baltimore, Md., January, 1909.

Northwestern Electrical Association. Annual meeting, Milwaukee, Wis., January, 1909.

PERSONAL MENTION.

MR. WILLIAM MARCONI, it is unofficially announced, is to receive the next Nobel prize in physics.

PROF. J. ROY ARMSTRONG, of Colorado College, has been commissioned by the City Council of Colorado Springs, Colo., to test the city street arc lamps.

MR. RICHARD O. HEINRICH, director of the European Weston Electrical Instrument Company, Berlin, Germany, is making an extended visit to this country.

MR. G. R. FOLDS has resigned as general manager of the West Penn Railways Company, Pittsburg, Pa., and will become general sales agent and assistant to the president of the H. W. Johns-Manville Company of New York, N. Y.

MR. C. H. SPOTTS, formerly manager of the paint department, and Mr. Walter F. Swearer, assistant at the general offices of the Joseph Dixon Crucible Company, Jersey City, N. J., are now associated with the Protectus Company. Mr. Spotts is secretary, and Mr. Swearer New York manager.

MR. J. R. GORDON, for many years southern district manager for the Westinghouse Electric and Manufacturing Company, has resigned from that company and accepted a position with the Western Electric Company, as power apparatus sales manager for its southern territory, with headquarters at Atlanta, Ga. He took charge of his new duties November 1.

MR HOMER E. NIESZ, manager of the Electrical Trades Exposition Company, Chicago, who has been indisposed for some little time, left Chicago November 16 for Hot Springs, Ark. Mr. Niesz will return to Chicago about the first of December, and it is hoped will then be prepared for the arduous work which the coming Chicago Electrical Show will require of him.

MR. FRANK J. SPRAGUE, of New York, passed through Chicago last week on his way to the Pacific Coast, where he is supervising the installation of a number of electric plants. While in Chicago he inspected the terminal facilities of the Illinois Central Railroad, and made a preliminary study of its traffic conditions as bearing on the electrification project.

MR. T. H. CEPERLEY has been appointed chief engineer of the Stuyvesant Falls power plant of the Albany & Hudson Railroad, to succeed W. G. Andrews. Mr. Ceperley was formerly chief engineer of the Newburgh Light, Heat and Power Company, having charge of plants at both Poughkeepsie and Newburgh.

MR. THEODORE N. VAIL, president of the American Telephone and Telegraph Company, was a passenger on the St. Louis, which sailed for Europe last Saturday. Mr. Vail said: "I shall take up no business while away. I am leaving at this time because there are no business matters in the way and no pressing problems for me to consider. The American Telephone and Telegraph Company has a clear outlook ahead, and I feel that I can go away for a two months' rest."

MR. WALTER ROBBINS, assistant general manager of the Wagner Electric Manufacturing Company, St. Louis, Mo., received, the other day, a postcard from A. W. Wyckoff, the Wagner company's genial Pittsburg representative, portraying the palatial residence of S. R. Dresser, at Bradford, Pa. A three-and-one-half-horsepower Wagner motor runs a vacuum cleaner in this residence, and the postcard bore the following legend: "This is the kind of a power house we always insist on having built around a Wagner three-and-one-half-horsepower motor; larger sizes are built in proportion."

MR. RICHARD C. McLAURIN, Professor of Physics in Columbia University, was elected on November 11 to the presidency of Massachusetts Institute of Technology made vacant by the resignation of Dr. Henry S. Pritchett, a year ago. Professor McLaurin has accepted, and will be inaugurated as soon as he can sever his connection with Columbia. The new president was born in Edinburgh thirty-eight years ago. He spent his boyhood in New Zealand, returning to England to complete a course at Cambridge, where he was graduated with high honors in law. He was afterward professor in the University of New Zealand, and later studied at McGill and Columbia, devoting himself to mathematics and physics.

ELECTRIC LIGHTING.

DALLAS, TEX.—E. A. Worden and others have applied for an electric-light and heating franchise.

ARTESIA, N. M.—Oscar A. Coates of Bisbee, Ariz., has been granted a franchise for an electric-light plant.

CUERO, TEX.—The Cuero Light and Power Company has been incorporated with a capital stock of $100,000.

SUPERIOR, WIS.—The Northwestern Lighting Company has been incorporated with a capital stock of $15,000.

DETROIT, MICH.—The Manufacturers' Light and Power Company, of Detroit, has been incorporated with a capital stock of $10,000.

WALLA WALLA, WASH.—The Washington-Oregon Traction Company has been granted a franchise for an electric light and power plant.

REEDSBURG, WIS.—A day circuit is to be established on the city electric power lines. An expenditure of $8,000 is contemplated in making the change.

CLIFTON SPRINGS, N. Y.—Richmond P. Pratt, of Clifton Springs, and E. VerPlank, of Manchester, who recently purchased the Manchester Mills, have formed the Manchester Power Company.

MISSOULA, MONT.—The Missoula Light and Water Company is planning to add to the capacity of its Missoula plant to meet the growing demand for electric service throughout the territory served.

IOWA CITY, IOWA.—The lighting committee of the city council has recommended asking for bids for 130 magnetite arcs. Bids are also asked for 250 incandescents in addition to the magnetite arcs.

KANSAS CITY, MO.—The Union Finance Company, of Kansas City, Mo., has applied for a fifty-year franchise to supply light in St. Louis County. It is proposed to supply it at twelve-and-one-half cents per killowatt-hour.

TAXCO, MEXICO—An electric power and lighting plant has been installed near Taxco, state of Guerrero, by the Compania Minera y Metalurgica. The power will be used to operate the machinery of the mines of the company.

ROGERSVILLE TENN.—The electric-light plant at Rogersville was destroyed by fire October 29, with a loss of $5,000, partially covered by insurance. The plant will be rebuilt at once, and is promised to be completed by December 15.

NEW CUMBERLAND, W. VA.—The Panhandle Electric Company, with principal office at Pittsburg, Pa., and chief works at New Cumberland, has been chartered with a capital stock of $25,000. One of the incorporators is J. L. Merrill, of Pittsburg.

ELLWOOD CITY, PA.—The City Council has decided to advertise for bids for installing an electric plant in Ellwood City. The people of the town favor a municipally-owned plant. The estimates of the cost of installing a plant have been from $11,000 to $13,500.

GUADALAJARA, MEXICO—George Mitchell and D. B. Russell, of New York, are preparing to install a hydro-electric plant near Guadalajara, to operate the machinery of a marble quarry which they own. They also expect to build an electric railway from their property to Guadalajara.

CHEYENNE, WYO.—The Citizens' Water and Power Company has been incorporated with the object of generating, distributing and selling electricity for light, power and heat in Laramie County, Wyoming, and in Colorado. The directors elected for the first year are George Bullock, G. A. Taff, F. M. McMahon, R. L. Holland and R. S. Ellison.

KEOKUK, IOWA.—The stock and franchise of the Keokuk & Hamilton Water Power Company has been transferred to financial interests which are expected to develop the waterpower of the Des Moines rapids. Fifteen million dollars will be required to develop 200,000 horsepower, and actual work must be begun by February 9, 1910.

CEDAR RAPIDS, IA.—W. G. Dows and Isaac B. Smith, of the Cedar Rapids & Iowa City Railway & Light Company, have purchased waterpower rights in the Cedar River at the Palisades, six miles below Cedar Rapids. A twenty-foot dam will be built, and it is estimated that 50,000 horsepower will be developed. Ultimately there will be an electric line to the Palisades and Mount Vernon.

CUERNAVACA, MEXICO—E. Conas, of Cuernavaca, treasurer of the state of Morelos, is erecting an electric power and lighting plant of 1,600 horsepower capacity at Cuernavaca. Mr. Conas also owns the street-railway system of that city and the power of his plant will be used to operate its cars. It will also furnish power and lights for the town. The plant will be finished about January 1.

GOSHEN, IND.—By a ruling of the Circuit Court the city of Goshen is prevented from rebuilding its commercial lighting system, at a cost of $40,000. The contract had been awarded to the Ironton Engine Company, of Ironton, Ohio. Taxpayers obtained an injunction on the grounds that the 2 per cent legal limit of indebtedness had been exceeded and that error was committed in not advertising for competitive bids.

McKINNEY, TEX.—At the regular meeting of the city council it was decided to purchase material for the extension of the city electric light system, a number of additional arc lights to be put up over the city. The material is to be purchased at once and the work of making the extension will soon be in progress. W. E. McKinnon of Dallas was elected superintendent of the city waterworks and electric light system.

NORTH ADAMS, MASS.—Plans for the building of a new electric-light plant to cost more than $100,00 have been formulated by the North Adams Gas Light Company. The accident of last summer, when a large flywheel burst, is partly responsible in determining the building of the new plant. The new station will have a complete equipment and the capacity will be practically doubled, from 2,500 horsepower to 4,000 horsepower.

ST. LOUIS, MO.—A meeting of business men and property owners in the district bounded by Fourth, Twelfth and Market streets and Washington Avenue, has been held to lay plans for the better and more uniform lighting of the down-town section of the city, especially in the district named. The meeting was under the auspices of the Lighting Committee of the Civic League, which includes J. L. Van Ornum, E. L. Andreon, Joseph D. Bascom, T. F. Chaplin, A. S. Langsdorf and John J. Lichter.

MEXICO CITY, MEXICO—The following applications have been made to the Mexican government recently for concessions to install hydro-electric plants: Mariano Alcerreca and Jose Jijar y Harro to erect a plant on the Santa Cruz and San Francisco creeks, near El Monte; Guillermo Brockman, to erect a plant on the Turbio River, state of Guanajuato; Tezuitlan Mining and Smelting Company, to erect a plant on the Sola River, state of Oaxaca; Isidro Medina, to erect a plant on the Ameca River, near Ameca, state of Jalisco; General Mariano Ruiz, to erect a plant on the Alica River, territory of Tepic; Gill S. Peyton, to erect a plant on the Lerma River, state of Jalisco; Armado I. Santa Cruz, to erect a plant on the Huitzilapam River, state of Puebla.

NOBLESVILLE, IND.—Work is progressing rapidly on the hydraulic dam which the White River Light and Power Company is building across White River, two miles north of Noblesville, and the company hopes to have the plant completed and in operation within the next sixty days. The dam is 300 feet long and develops a head of eighteen feet. The company expects to furnish Noblesville with electricity, and hopes to branch out and supply Cicero, Atlanta and Arcadia and possibly reach as far as Tipton, Lebanon, Frankfort and Elwood. Wallace Campbell, of Anderson, who is promoting an interurban line from Anderson through Noblesville to Lebanon and Crawfordsville, is negotiating with the company for power to operate the road. Mr. Campbell expects to finish the line between Anderson and Noblesville within the next year and he has asked the company for prices for sufficient power to operate the road between these two points.

PROPOSALS.

STREET LIGHTING, TAMPA, FLA.—Sealed bids will be received at the office of the city clerk until November 27 for lighting the streets of the city of Tampa with one hundred or more electric arc lights. Specifications may be had on application to the city clerk.

POST OFFICE AT COLDWATER, MICH.—The office of the Supervising Architect, Treasury Department, Washington, D. C., will receive sealed proposals until December 22 for the construction (including plumbing, gas piping, heating apparatus, electric conduits and wiring) of the post office at Coldwater, Mich., in accordance with specifications, which may be obtained from the custodian of the site at Coldwater or at the office of the supervising architect.

GOVERNMENT BUILDINGS AT ALASKA-YUKON-PACIFIC EXPOSITION, SEATTLE, WASH.—The office of the Supervising Architect, Treasury Department, Washington, D. C., will receive sealed proposals until December 21 for the construction of the United States government buildings at the Alaska-Yukon-Pacific Exposition at Seattle, Wash., in accordance with specifications, which may be obtained from the custodian of the Federal Building at Seattle, the superintendent of construction at the post office at Tacoma, Wash., or at the office of the supervising architect.

NEW PUBLICATIONS.

THE GOLDEN GATE—A very interesting brochure has been published by Adolph M. Schwarz, attorney and counselor-at-law, 299 Broadway, New York, N. Y., describing the beauties of San Francisco, Cal. Mr. Schwarz has established a chain of offices in several of the large commercial centers. It is his opinion, after traveling a great deal throughout the country, that at the Golden Gate there is the grandest opportunity for really enjoying one's work, and living.

NEW MANUFACTURING COMPANIES.

CHICAGO, ILL.—The Grand Flaming Arc Lamp Company has been capitalized at $10,000 to deal in appliances for electric lighting and heating. A. J. Lester, J. D. Ferguson and L. M. Greenlaw are the incorporators.

EDUCATIONAL.

The University of Michigan has accepted plans for an addition to the new engineering building, to be built at a cost of $75,063.75. An appropriation of $1,100 was also made for the construction of a new engineering camp at Douglas Lake.

ELECTRICAL SECURITIES.

Further breadth and activity developed in the bull campaign in last week's stock markets, with dealings more comprehensive and of a higher average than for some time. New high levels in various industrials were made for the year. Commission firms report great interest on the part of the public, and there has been large buying in this direction. The bulk of the trade is reported from western communities, which indicates the wider range of prosperity in this section than anywhere else in the country. The refusal of the United States Circuit Court of Appeals of the application for a rehearing of the Standard Oil decision was regarded favorably, and offset the unfavorable effect of the decision declaring the American Tobacco Company illegal and in restraint of trade under the Sherman Anti-Trust law. This case will be appealed by the company, and is expected to drag along for some time. There has been no lack of reports fostering increased interest, and aside entirely from speculative buying there has been a difficulty in meeting a considerable investment demand. The $20,000,000 bond issue distributed by the Illinois Central was successful beyond the expectations of the most sanguine, and the announcement of the new New York city $12,500,000 bond issue at 4 per cent is regarded as a significant indication of the better values which are now placed on these investments. Money, both call and time, ruled a little higher, and this is what has been expected and generally forecasted. It is the opinion of those best informed, however, that there will be no shortage of money, except possibly a temporary flurry near the end-of-the-year settlements. Reports continue to show the generally improved conditions of business, although there are those who do not hesitate to say that these reports are exaggerated. Railroad earnings, however, continue to show a considerable betterment, and in many well-placed lines there is no doubt whatever of a large and likely-to-be-maintained improvement.

Dividends have been declared upon the following electrical securities: Kings County Electric Light and Power Company; regular quarterly dividend of two per cent, payable December 1. American Railways Company; regular quarterly dividend of one and one-half per cent, payable December 15 to stock of record November 28, books close November 28 and reopen December 3. Grand Rapids Railway Company; regular quarterly dividend on the common stock of one per cent, payable December 1 to stock of record November 15. Chicago Railways Company, a dividend of $4 per share from accrued income to August 1, payable November 15 to stock of record November 12. Philadelphia Electric Company; semi-annual dividend of three per cent, payable December 15 to stock of record November 21. This is an increase of one per cent per annum, putting the stock on a six per cent basis.

ELECTRICAL SECURITIES FOR THE WEEK ENDED NOVEMBER 14.

New York:	*Closing.*
Allis-Chalmers common	13⅝
Allis-Chalmers preferred	47⅝
Brooklyn Rapid Transit	55⅞
Consolidated Gas	149½
General Electric	156½
Interborough-Metropolitan common	13¾
Interborough-Metropolitan preferred	35¾
Kings County Electric	128
Mackay Companies (Postal Telegraph and Cables) common	76¼
Mackay Companies (Postal Telegraph and Cables) preferred	70½
Manhattan Elevated	144
Metropolitan Street Railway	31½
New York & New Jersey Telephone	119
Western Union	64½
Westinghouse Mfg. Company	91¼

At the annual meeting of the Manhattan Railway Company Dumont Clarke was elected a director to fill the place of G. P. Morosini, deceased, and Frank J. Gould was elected a director to fill a vacancy. The old officers and the members of the executive committee were re-elected.

Boston:	*Closing.*
American Telephone and Telegraph	131¾
Edison Electric Illuminating	250
Massachusetts Electric	57¾
New England Telephone	124½
Western Telephone and Telegraph pref	70
Philadelphia:	*Closing.*

Chicago:	*Closing.*
Chicago Telephone	.....
Commonwealth Edison	108¼
Metropolitan Elevated preferred	.....
National Carbon common	85
National Carbon preferred	104

Following the annual meeting of the Commonwealth-Edison Company, officers were re-elected.

It is semi-officially stated that an extra dividend on Chicago City Railway stock will be declared before the end of the present fiscal year, making a total of nine per cent for the year. The consolidation of the City Railway and Chicago Railways properties is discussed by controlling interests, but it is thought that nothing will be done until Chicago Railways has cleared its deck of various legal entanglements.

South Side Elevated advanced eight points last week. A director states that the company has a substantial cash surplus. The policy of the directors on dividends at the meeting the last of the month will be governed by future increased traffic prospects.

ELECTRIC RAILWAYS.

SAND POINT, IDA.—V. M. Smith has made application for a franchise for a street railway.

McKINNEY, TEX.—The proposed Mineral Wells & Northern Electric Railway is to be extended through Decatur and Denton to McKinney.

BELLEFONTAINE, O.—The line of the Ohio Electric Railroad, from Lakeview to Lima, has been completed and turned over by the contractors.

TOLEDO, OHIO—Construction work on the Lima-Toledo branch of the Ohio Electric Railway system is nearly completed. All of the heavy grading and filling have been finished.

MARSHALL, TEX.—The City Council has granted a franchise to M. Turney and associates to build and operate an electric car line and to furnish lights and power for a period of twenty-five years.

HUNTSVILLE, ALA.—An electric railway company is running a survey to Monte Sano, with the purpose of finding the most available route from the city to the top of the mountain. A railway to the mountain is planned for future construction.

NASHVILLE, TENN.—President H. H. Mayberry, of the Nashville Interurban Railway, makes the announcement that track laying for the road will begin at once and the work will be pushed to a rapid conclusion.

TORREON, MEXICO—A syndicate of wealthy Chinamen are building an electric railway system in Torreon and an interurban line that will connect the city with the town of Matamoros. The system will have about twenty miles of track. The syndicate are operating under the name of the Compania Bancaria y de Tranvias Wah Yick.

KANSAS CITY, MO.—A proposed interurban electric line, to pass through Bonner Springs, Turner and other small towns west of Kansas City, and to connect with the Metropolitan at Argentine, is being talked of by the farmers along the proposed route and the residents of the towns through which it will pass. The farmers say they will grant a right-of-way and are also willing to take stock in a company if formed.

RICHMOND, VA.—A charter has been granted to the Richmond, Urbanna & Peninsular Railway Company, whose president is John C. Robertson of Chesterfield. The capital stock of the company is placed at from $100,000 to $300,000. The proposed new line is to connect with the present electric line at Ashland and will run from West Point to Urbanna, a distance of sixteen miles, through a thickly populated section.

WASHINGTON, PA.—Work has begun on the construction of an interurban trolley line from Monongahela to Washington. Some time ago a franchise was granted the Monongahela and Carroll Street Railway Company to build its line in Monongahela. The company has filed extensions and is now authorized to construct its line from Monongahela to Washington, including a branch beginning near Ellsworths and to run to Marianna.

SEATTLE, WASH.—Within thirty days the Milwaukee road will be running trains between the Columbia River and the western portal of the St. Paul tunnel in St. Paul pass in the Bitter Root mountains. The tunnel through the Bitter Root mountains is 8,750 feet long. One end is in Montana, the other in Idaho. There are fifteen spans in the bridge over the Columbia, and the piers are being built and the steel framework is being pushed rapidly out over the stream.

WINSTON-SALEM, N. C.—A project of some magnitude is announced by Dr. H. P. McKnight, lessee of Vade Mecum Springs, Stokes county, about thirty-two miles from Winston-Salem, who says he will within thirty days start a force of men to work on building an electric car line from the Twin City to the springs. Later, he declares, he will continue the line to Spray and Leaksville, provided the rights-of-way can be secured. Dr. McKnight has surveyors already on the right-of-way which he has obtained.

CHICAGO, ILL.—The Chicago and Oak Park Elevated Railway will have a 155-foot viaduct erected on its main line on Lake street, between Clinton and Canal streets. This will be necessary to secure adequate headroom below its structure for the eight-track approach that the Chicago and Northwestern Railway will build into its new $20,000,000 terminal station. The approaches of the elevated structure have been raised already to an increased height of six feet at the point where the viaduct will be erected.

CHICAGO, ILL.—An innovation in traction management, consisting of an attempt to prevent overcrowding before it begins, has been introduced by the Northwestern Elevated Railroad, in connection with its new "stub" station at North Clark and North Water streets. The trains running into this station will not cross the river. Twenty-five thousand postcards, asking patrons of the road whether they intend to avail themselves of the new accommodations, are being distributed at all stations. The replies will govern the number of trains per day.

GARDEN CITY, KAN.—Work has been commenced on the electric road to be built by the Kansas & Colorado Electrical Transmission Company, which also proposes to build power plants to furnish electrical power for industrial plants in the Arkansas valley west of Garden City. The railroad line is to run from Canon City, Colo., to Dodge City, Kan., with a branch line from Garden City to Scott, Kan., in all 387 miles. The entire survey has been made and grading is completed in Colorado for a distance of about twelve miles northeast of Pueblo.

CHICAGO, ILL.—Since the directors of the Illinois Central Railroad announced that the Chicago terminal is to be electrified, commuters of the Burlington are agitating electrification of the Burlington between Downers Grove and Chicago. With the exception of the Illinois Central and the Chicago & Northwestern the Burlington has the heaviest suburban passenger business of any railroad entering Chicago, and as the company's right-of-way passes through almost the heart of the business district there have been many complaints about the smoke from the trains.

BUFFALO, N. Y.—At the annual meeting of the stockholders of the International Traction Company Nelson Robinson was elected a director, succeeding J. F. Slocum; other directors were re-elected. Subsequently the directors held their business meeting and appointed an executive committee of T. E. Mitten, Nelson Robinson and Thomas Penny. J. W. Crawford was elected secretary, to succeed J. F. Slocum. Thomas Penny, who was elected by the old board about a month ago, succeeding Henry J. Pierce, resigning president, was elected president again by the new directors.

EAST ST. LOUIS, ILL.—In order to forestall a threatened attempt of the East St. Louis and Suburban Railway Company to resume the collection of a ten-cent passenger fare between the Belleville Public Square and Edgemont, the present western terminus at Belleville, the Belleville City Council has passed an ordinance providing a penalty of not over $200 for each offense in collecting more than five cents for a single street-car ride in the city limits. An additional provision of the ordinance is that a transfer given from one line to another within the city limits shall be good for one hour after its issuance.

SAN FRANCISCO, CAL.—The new power plant of the United Railroads of San Francisco at North Beach, on which the company has been working for several months past, is now nearly complete. The new turbo-generator equipment will be capable of producing 5,000 kilowatts, supplying about 140 additional cars. The United Railroads at present get a large proportion of their current from the California Gas and Electric Company and the City Electric Company, and depend upon the latter concerns to such an extent that any interruption of their service seriously interferes with the operation of the cars. While outside power will continue to be employed almost as largely as at present, the new equipment will enable the United Railroads to give constant service regardless of any accident that is likely to occur to the machinery of either of the other companies.

TELEPHONE AND TELEGRAPH.

HOLLAND, TEX.—The Rural Telephone Company has been incorporated with a capital of $400.

BLUEFIELD, W. VA.—The Graham Telephone Company has elected the following officers: President, R. L. Gillespie; secretary and treasurer, P. J. Ritter; general manager, Dr. Carl Greever, of Tazewell.

OAKVILLE, TEX.—A. J. Moore of San Antonio, owner of the Eureka telephone system, has bought the lines and equipment of the rural telephone system, formerly belonging to E. J. Atchley, and is preparing to overhaul the property.

NORFOLK, VA.—The Common Council of Norfolk is considering the proposed merging of the two local telephone companies. The industrial commission, which has devoted considerable time to hearing all sides of the proposed merger, is expected to make a recommendation to the council.

LINCOLN, NEB.—The Nebraska-Iowa Long Distance Telephone Company has been incorporated with a capital of $1,600,000 by F. J. Day, G. O. Beno, E. H. Merriam, F. R. Davis, H. B. Jennings, F. H. Keys, T. G. Turner, W. H. Kimball and C. A. Laubach. $1,000,000 of the stock will be common, and to this stock alone will voting power be accorded.

CHESANING, MICH.—Local business men have organized a home telephone company and have now a paid-in capital of $10,000. C. O. Trask of Saginaw, organizer of the Valley Company in that city, prepared plans and gave other assistance in the organization of the Home concern. The exchange is to be equipped with the latest devices for good service, and will accommodate 250 subscribers.

SANDY HOOK, N. J.—Officers of the Signal Corps are experimenting with a long-distance wireless telephone between the Sandy Hook proving ground and New York city. Heretofore the longest distance covered by a wireless telephone has been between eight and ten miles, but it is claimed that the wireless apparatus now being experimented with will operate over a distance of forty miles.

CHICAGO, ILL.—The Illinois Tunnel Company, which operates an automatic telephone exchange in the downtown district of Chicago, in connection with its freight tunnels, has appealed to the city council for a grant of two years' extension of its telephone franchise. The company declares that, owing to the energy concentrated in pushing the freight and tunnel business, the development of the telephone exchange had been prevented, and only 5,000 of the 25,000 telephones stipulated to be installed at this time have been subscribed for so far.

SEATTLE, WASH.—The signal service wireless stations in Alaska have made another record, removing all doubt as to the feasibility of sending wireless messages overland. Fort Gibbon, several hundred miles inland, is receiving messages from Nome and St. Michael, 500 miles distant, with many ranges of hills between the two stations. A message sent by the steamer Northwestern 1,100 miles west of Cape Flattery to the United Wireless station at Cordova was copied. The message traveled about 1,200 miles in an air line over two ranges of mountains, capped with snow.

CHIHUAHUA, MEX.—The Intermountain and Mining Telephone Company of Chihuahua has adopted plans for the building of the largest long-distance telephone system in Mexico. It recently completed its first 100 miles of telephone line connecting the principal mines in the Guaronapeta mining district. In addition to this completed line the company is preparing to build a system of lines radiating out of Casas Grandes, connecting all of the principal mines within a radius of 100 miles with that town. From Casas Grandes a long-distance line will be built to El Paso, Tex., a distance of about 165 miles. Another line will be built from Guaronapeta to Madeira, where it will connect with the long-distance telephone system owned and operated by the American syndicate, which has established a large lumber business in the mountains of that part of the state. The plans call for the building of more than 500 miles of long-distance lines.

INDUSTRIAL ITEMS.

THE PACIFIC ELECTRIC HEATING COMPANY, whose main office and factory is at Ontario, Cal., has removed its Chicago factory to 63 and 65 West Washington Street.

THE BAILEY-WRIGHT COMPANY, Cleveland, Ohio, announces its incorporation as a general advertising agency, with offices in the Citizens' Building. George J. Bailey and Harland J. Wright compose the firm.

THE AMERICAN CONDUIT COMPANY, 140 Nassau Street, New York, has mailed to its friends a picture postcard showing the method of hauling its bituminized fiber conduit to the trench in Belgium by means of dog carts.

THE PETTINGELL-ANDREWS COMPANY, Boston, Mass., has published a catalogue devoted to a description of the P-M remote-control switch for direct and alternating currents. Copies of this catalogue will be furnished upon request.

THE NERNST LAMP COMPANY, Pittsburg, Pa., in its monthly house journal, *Lux*, for November illustrates some new installations of Nernst lamps under a variety of conditions, which show the useful applications of this popular illuminant.

THE BY-PRODUCTS FUEL COMPANY'S engineering department requests catalogues relating to mining machinery and equipment, power plants, coke ovens, and machine tools. The department may be addressed at Moundsville, W. Va.

THE CENTRAL ELECTRIC COMPANY, Chicago, Ill., is distributing a new folder describing its Type B knife switches, which conform to the National Electric Code standard. A complete list is given of the various ampere capacities, possible combinations and prices. This circular will be sent upon request.

THE WILLARD STORAGE BATTERY COMPANY, Cleveland, Ohio, has opened an office and battery depot at 1876 Broadway, corner Sixty-second Street, New York city. At this place all kinds of batteries and parts will be kept in stock. Orders for batteries and parts for New York and vicinity will be assembled at this depot, which will insure prompt service and quick deliveries.

THE WESTERN ELECTRIC COMPANY, Chicago, Ill., in bulletin No. 5532, gives a graphic description, with illustrations, of Victor flaming arc lamps. These lamps have been utilized to great advantage in a number of difficult installations, and the treatment given in the bulletin will afford considerable information to those desiring knowledge on this subject. Copies will be furnished upon request.

H. M. BYLLESBY & COMPANY, Chicago, announce the declaration of the usual quarterly dividend upon the preferred stock of the Mobile Electric Company, of Mobile, Ala., of 1½ per cent, payable November 16 to stockholders of record November 9. The preferred stock books of the company, both in New York and Chicago, are closed from November 9 to the opening of business, November 16.

THE OSWEGO MACHINE WORKS, Oswego, N. Y., extends an invitation through Niel Gray, Jr., its proprietor, to visit its new Chicago and New York salesrooms, where its most recent power and hand-driven paper-cutting machines are shown running with all the latest improvements. The New York store is located at 203 Wooster Street, and the local office, 150 Nassau Street, is in charge of W. S. Timmis, manager. The Chicago store and office is at 347 Dearborn Street, J. M. Ives, manager.

THE CROCKER-WHEELER COMPANY, Ampere, N. J., in its bulletin No. 109, just issued, describes small generating sets consisting of Crocker-Wheeler generators and Type D engines made by the U. S. Rapid Fire Gun & Powder Company, and ranging from two to nineteen kilowatts, which are used to advantage for complete small lighting plants. The design of the generators is described in Crocker-Wheeler bulletin No. 100. Direct-current switchboard panels manufactured by the same company, and illustrated in bulletin No. 106, may be assembled to form a switchboard of any size and capacity. The bulletin contains suggestions as to the instruments and apparatus necessary on switchboards. General direct-current information and formulas for calculating the voltage drop in any feeder, the size of generator and engine required for lighting and power plants and a table of resistance and carrying capacity of wires are given in bulletin No. 107, which also describes the Crocker-Wheeler line of direct-current lighting and power generators of large sizes.

ROBERT W. HUNT & COMPANY, consulting and inspecting engineers, 1121 The Rookery, Chicago, Ill., have been awarded, by the Chicago & Northwestern Railroad Company, the inspection of the structural materials entering into its new terminal station, of which the steel will amount to about 24,000 tons. The same company has also been given the inspection of the steel to be used in the new Blackstone Hotel, now being erected at the corner of Michigan Avenue and Hubbard Court, Chicago.

THE WARD LEONARD ELECTRIC COMPANY, Bronxville, N. Y., has developed a compact resistance unit, having the Edison base, and suitable for mounting in a lamp socket. The head of each porcelain tube is arranged with a recess in which a small brass number-plate is inserted, on which the resistance is marked. The tube has a capacity of fifty watts and can be wound with any resistance up to 1,500 ohms. Resistance lamps have been used in many laboratories and telegraph exchanges in the past, but have the disadvantage that the resistance alters and ages and that they occupy considerable space and are costly. This tube is of the standard Ward Leonard type, and the wire has a zero temperature coefficient and is protected from electrical, chemical and mechanical depreciation. Any size Ward Leonard tube up to 200 watts capacity can be mounted in this manner.

THE METROPOLITAN ELECTRICAL SUPPLY COMPANY, 184 Lake Street, Chicago, announces a new type of rheostat, giving ten to fifty times as many steps as in the ordinary rheostat, thus securing close control of the current. The instrument is compact, durable and neat, and the manufacturers believe this to be the ideal rheostat for the laboratory, and for all classes of work where fine control is an essential feature. The same company also makes speed regulators, field rheostats, battery-charging rheostats, moving-picture-machine rheostats, theater dimmers, etc.

MANNING, MAXWELL & MOORE, 85 Liberty Street, New York, N. Y., are distributing their new tool catalogue. This gives a thorough presentation of modern machine tools designed for service with high-speed steel and with the latest devices in motor drives. The tools illustrated and described are grouped carefully for convenient investigation. Great care and expense have been given to the production of this catalogue, the quality of paper, the arrangement of detail, and the execution making it a very valuable addition to literature of this subject. For the convenience of those using the book, a careful codification of all types of machine tools and appliances illustrated has been made. The catalogue contains 1,775 pages of information regarding the latest designs of machine tools now on the market.

RECORD OF ELECTRICAL PATENTS.

Issued (United States Patent Office) November 10, 1908.

903,164. ELECTROLYTIC APPARATUS. Paul Borgnet, Liege, Belgium. Filed May 11, 1907. The cathode is arranged to float unsupported in the bath and the anode is arranged in proximity to the cathode.

903,165. THERMOSTATIC CIRCUIT-CONTROLLER. George H. Bowen, Boston, Mass. Filed June 20, 1907. A glass tube encloses a movable member and sustains its fusible support.

903,177 and 903,178. SYSTEM FOR CONTROLLING ONE OR MORE ELECTRIC MOTORS. Henry H. Cutler, Milwaukee, Wis., assignor to The Cutler-Hammer Manufacturing Company, Milwaukee, Wis. Filed August 11, 1905. In a multiple-unit train-control system there are electromagnetic switches on each car responsive to different voltages.

903,193. SYSTEM OF CONTROL. Ray P. Jackson, Wilkinsburg, Pa., assignor to Westinghouse Electric and Manufacturing Company. Filed May 8, 1905. Renewed January 20, 1906. A traction motor-control system has a master controlling switch and a switch operated by the motor, both connected to the transformer winding.

903,195. TESTING-GALVANOMETER. Harry T. Johnson, New York, N. Y., and Charles E. Avery, Jersey City, N. J. Filed March 22, 1906. A flat magnet core is disposed in a horizontal central position relatively to the needle and has a greater width at its center than at its ends.

903,197. TELEPHONE-TRANSMITTER. William Kaisling, Chicago, Ill., assignor to Milo G. Kellogg, Chicago, Ill. Filed March 15, 1906. The transmitter comprises a plane diaphragm fixed at its center, a granule chamber mounted thereon, co-operating electrodes within the chamber and a body of granular carbon between the electrodes.

903,198. PRODUCING PHONOGRAPHIC RECORDS. Isidor Kitsee, Philadelphia, Pa. Filed March 6, 1908. The method consists in first recording the sound waves upon a suitable surface and electroplating upon the parts of the surface upon which no record has been made.

903,199 and 903,200. PHONOGRAPHY. Isidor Kitsee, Philadelphia, Pa. Filed March 12 and June 11, 1908. These are modifications of No. 903,198.

903,203. POUSSE-CAFE MACHINE. John Krivanek, San Francisco, Cal. Filed October 29, 1907. A series of chambers is equipped with valves and electrically controlled mechanism by which the valves are actuated to successively deliver a liquid from each of the chambers into a glass.

903,213. FLUID-GAGE. Morris Martin, Boston, Mass. Filed April 13, 1907. A removable carrier is provided with a magnetic needle and a device normally operative to lock the needle, combined with a gage head having a stud and a movable magnet.

903,221. OUTLET-BOX COVER. George B. McBean, Chicago, Ill., assignor to Mechanical and Electrical Manufacturing Company, Chicago, Ill. Filed February 23, 1907. Comprises a non-conducting socket and an annular metallic cover embracing the socket.

903,251. CIRCUIT-CLOSING DEVICE. Alfred A. White, Bangor, Me., assignor to National Trade Tapper Company, Bangor, Me. Filed May 18, 1907. Consists of a clock mechanism with a segment wheel and a contact member adapted to intermittently contact therewith.

903,257. CONTACT-OILER. Albert D. Wiswall, Utica, N. Y. Filed June 12, 1907. Renewed April 8, 1908. Combined with a controller having a rotatable shaft with contact plates thereon and fingers engaged by the plates, is a rotatable roll of lubricant-saturated material in engagement with the plates.

903,287. PROCESS OF THE MANUFACTURE OF INSULATING MATERIALS. Hermann v. d. Heide, Datteln, Germany, assignor to The Firm of Wunner'sche Bitumenwerke G. M. B. H., Datteln, Germany. Filed May 31, 1907. Consists in mixing pitch and heavy coal tar oils, emulsifying this mixture with a solution of alkaline reaction and water-glass, and oxidizing the emulsion with superoxide of barium.

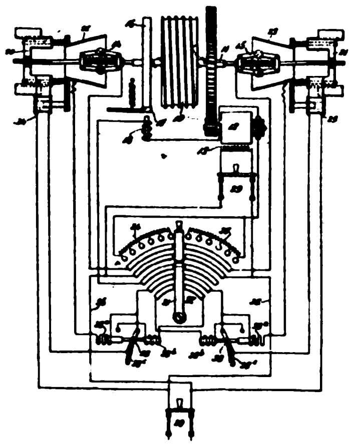
903,288. MOTOR-CONTROLLING SYSTEM. Clark T. Henderson, Milwaukee, Wis., assignor to The Cutler-Hammer Manufacturing Company, Milwaukee, Wis. Filed March 14, 1907. There are means for maintaining the main switch closed upon the stopping of the motor until the field resistance device removes all the resistance from the field circuit.

903,316. INSULATING COVERING FOR PIPES. Alois Reimann, Zizkov-Prague, Austria-Hungary. Filed July 22, 1908. A cord coated with water-glass is coiled around the pipe, spun glass filling the spaces between the cord coils.

903,319. THERMOSTAT FOR ELECTRIC HEATERS. Earl H. Richardson, Ontario, Cal., assignor to Pacific Electric Heating Company, Ontario, Cal. Filed January 2, 1908. A heat-controlled cut-out for an electric flat iron.

903,331. TYPE-CASTING AND COMPOSING MACHINE. Oddur V. Sigurdsson, New York, N. Y., assignor to Oddur Manufacturing Company, New York, N. Y. Filed June 25, 1906. A number of type-casting units are provided with an electromagnetic starting device for each unit and a set of operating keys, any of which when manipulated is adapted to complete the circuit.

903,338. CONTROLLER CONSTRUCTION. Emmett W. Stull, Norwood, Ohio, assignor to Allis-Chalmers Company and The Bullock Electric Manufacturing Company. Filed March 31, 1906. Construction of the blow-out magnet for a drum-type controller is described.

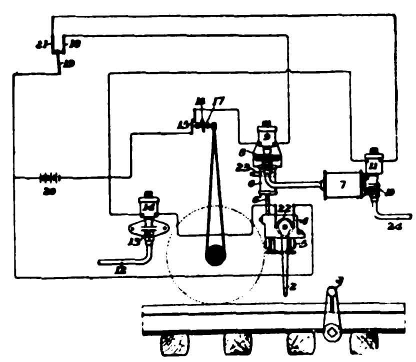


903,348.—CONTROLLER.

903,348. CONTROLLING APPARATUS. Albert G. Wessling, Norwood, Ohio, assignor to Allis-Chalmers Company and The Bullock Electric Manufacturing Company. Filed December 9, 1907. There are means for interrupting the supply of power to a hoisting motor when the latter is approaching a predetermined stopping point.

903,359. AUTOMATIC CONTROL FOR RAILWAY TRAINS. John P. Coleman, New York, N. Y., assignor to the Union Switch and Signal Company, Swissvale, Pa. Filed November 6, 1907. An electromagnet controls the air-brake valve and is itself controlled by the speed of the train.

903,366. TROLLEY POLE. Seybert D. Fenimore, Folcroft, Pa. Filed December 4, 1907. The pole has upper and lower sections connected by a knuckle joint.



903,413.—SPEED CONTROL OF TRAINS.

903,383. ELECTRODE FOR ARC LAMPS. Franz Janecek, Karlin, near Prague, Austria-Hungary. Filed May 16, 1907. Consists of a rod provided with a longitudinal dovetailed groove and a ladder-shaped metal strip located and held in the groove by its own resiliency.

903,401. ELECTRIC-LAMP SHADE HOLDER. Franklin Overbagh, Evanston, Frank E. Ayers, Hinsdale, and Irvin H. Brent, Chicago, Ill., assignors to Overbagh & Ayres Manufacturing Company, Chicago, Ill. Filed April 20, 1908. A flat annular sheet-metal body is provided with a number of projections which constitute a series of resilient prongs provided with studs spirally arranged and engaging a clamping ring.

903,404. METHOD OF SEPARATING ELECTRO-DEPOSITED METALS FROM LEAD MATRICES. Charles Reverdys, New York, N. Y., assignor to F. Wesel Manufacturing Company, Brooklyn, N. Y. Filed October 25, 1907. Consists in treating the surface of a lead matrix with a blast of carbon dioxide previous to producing the electro-deposit thereon.

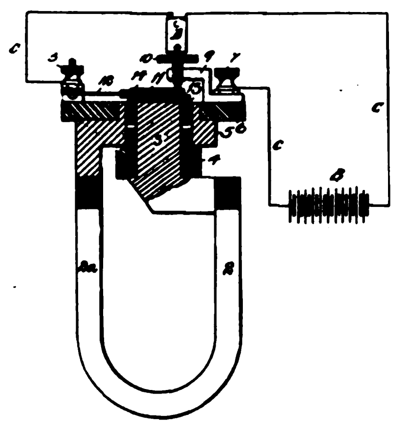
903,410 to 903,413, inclusive. APPARATUS FOR AUTOMATICALLY CONTROLLING THE SPEED OF TRAINS. Jens G. Schreuder, Edgewood Park, Pa., and Vibe K. Spicer, Chicago, Ill., assignors to the Union Switch and Signal Company, Swissvale, Pa. Filed August 3, 1907. A trip device for actuating the brake-controlled valve is normally held in operative position and shifted therefrom by a motor. Means actuated by the speed of the train control the operation of the motor.

903,414 and 903,415. COMBINED SIGNAL AND SPEED-CONTROLLING MECHANISM FOR RAILWAY TRAINS. Jens G. Schreuder, Edgewood Park, Pa., and Vibe K. Spicer, Chicago, Ill., assignors to the Union Switch and Signal Company, Swissvale, Pa. Filed August 3, 1907. A stop signal and caution signal have each a separate track stop and actuators shift the stops into and out of operative positions.

903,416 and 903,417. APPARATUS FOR AUTOMATICALLY CONTROLLING THE SPEED OF TRAINS. Jens G. Schreuder, Edgewood Park, Pa., and Vibe K. Spicer, Chicago, Ill., assignors to the Union Switch and Signal Company, Swissvale, Pa. Filed August 8, 1907. These are modifications of Nos. 903,410 to 903,413.

903,499. ELECTRIC-LIGHT STAND. Jefferson F. Pierce, Tampa, Fla. Filed May 11, 1908. The stand has a normally concealed coiled spring, the lower portion of which constitutes a clamping member.

903,508. ELECTRIC PICK MINING MACHINE. Alfred Sandstrom, Chicago, Ill., assignor to John F. Bush, Chicago, Ill. Filed April 1, 1904. Renewed April 7, 1908. An electromagnet holds a reciprocatory tool in retracted position and a motor produces sufficient air pressure to release the tool from control of the magnet and to thrust it forward.



903,745.—INTERRUPTER.

903,547. TELEPHONE SYSTEM. William W. Dean, Chicago, Ill., assignor to Kellogg Switchboard and Supply Company, Chicago, Ill. Filed June 29, 1903. Relates to signaling means for a common-battery system.

903,552. LIFTING MAGNET. Arthur C. Eastwood and Frederick R. Fishback, Cleveland, Ohio, assignors to the Electric Controller and Supply Company, Cleveland, Ohio. Filed April 4, 1908. The magnet has a winding of low resistance adapted for operation in series with an electric hoisting motor.

903,561. TELEPHONE SYSTEM. Joseph A. Geller and Stephen H. Geller, Chicago, Ill. Filed November 4, 1907. This patent covers a selective controlling mechanism for the signaling and receiving circuits.

903,568. ELECTRICAL CONTACT-MAKER. John H. Hart, Memphis, Tenn. Filed January 20, 1908. A lever is yieldingly suspended across the path of a wire.

903,577. ELECTRIC FLOOR PUSH-BUTTON. Henry F. Keil, Bronxville, N. Y. Filed March 3, 1908. Consists of a face plate, a plunger, two spring fingers and an insulating body to support the same.

903,580. ELECTRIC-CURRENT REGULATOR. David R. Knapp, Philadelphia, and Howard E. Cade, Pencoyd, Pa. Filed May 29, 1907. A regulator for a storage battery charging system.

903,592. POWER GENERATOR. Charles J. Low, Chelan, Wash. Filed January 3, 1907. A wheel is mounted on the shaft in front of the boat and drives an electric generator that supplies current to the propelling motor.

903,640. ELECTROMEDICAL APPARATUS. Reinhold H. Wappler, New York, N. Y., assignor to Wappler Electric Controller Company, New York, N. Y. Filed December 30, 1907. Comprises a coil, an interrupter disc, and means for simultaneously rotating the disc-actuating means for taking a sinusoidal shunt current from the coil.

903,653. GEARING. Arthur V. Allen, Chicago, Ill. Filed April 6, 1907. On top of the field frame of a motor is mounted a bracket for an adjustable friction gearing.

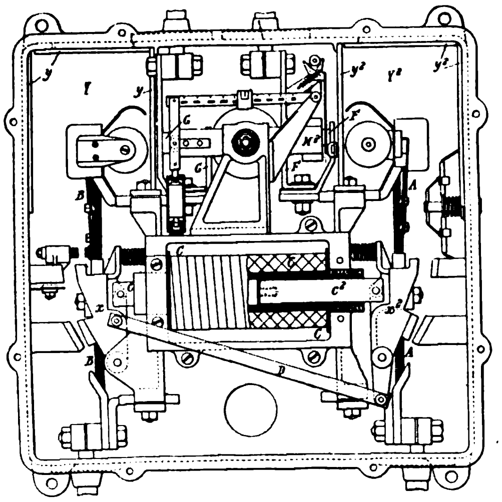
903,689. AIR AND GAS ENGINE. Hugh T. Dunn, New York, N. Y., assignor of one-half to Benjamin A. Jackson, New York, N. Y. Original application filed January 22, 1902. Divided and this application filed April 28, 1903. A pin mounted in a reciprocating arm makes contact between two stationary electrodes in the cylinder.

903,692. FEEDER-WIRE INSULATOR. George M. Finckel, Columbus, Ohio, assignor to the Sackett Mine Supply Company, Columbus, Ohio. Filed May 20, 1908. The insulator body has a through opening provided with a keyway.

903,968. TROLLEY WHEEL. Edmund J. Fredericks and Dilla R. Fredericks, Ohio, Ill., assignors to Lucien F. Hutchens, Minnie Remsburg and Dora Chase, Conneaut, Ohio. Filed September 27, 1907. A harp with oil chambers formed therein carries a hollow axle having apertures so that the oil chambers communicate with the axle and conduct the oil to the wheel.

903,705. ROTARY SNAP-SWITCH. Gilbert W. Goodridge and George B. Thomas, Bridgeport, Conn., assignors to the Perkins Electric Switch Manufacturing Company, Bridgeport, Conn. Filed January 3, 1908. The switch piece consists of a central blade with contact ends, top and bottom plates, and intermediate insulating sheets, the top plate having arms and an indicating dial clamped thereon.

903,733. TELEPHONE BRACKET. Benjamin M. Lampert, Cedar Bluffs, Neb. Filed June 10, 1908. Depression of a pedal opens the lazy-tong suspension for a desk telephone.



903,791.—DOUBLE-POLE CIRCUIT BREAKER.

903,745. INTERRUPTER. Carl E. Pearson, Lansing, Mich., assignor to Charles H. Bates and James H. Wellings, Lansing, Mich. Filed July 10, 1907. A make-and-break apparatus is provided with a tongue adapted to make connections with a contact point, a conductor being secured to the tongue and located in a permanent magnetic field.

903,752. PROCESS OF FORMING PLATES FOR STORAGE BATTERIES. William Morrison, Chicago, Ill., assignor to George Rumrill Coryell, Chicago, Ill. Filed December 26, 1902. Consists in subjecting the lead plates to electrochemical action in a solution formed by a mixture of sulphuric and nitric acids and permanganate of potash.

903,768. SIGN RECEPTACLE. Clarence D. Platt, Bridgeport, Conn., assignor to the Bryant Electric Company, Bridgeport, Conn. Filed December 12, 1907. A lamp receptacle has a body and a ring to attach it to the sign plate in combination with means to lock the receptacles to the sign plate in a number of positions.

903,785. SIGNAL SYSTEM. John J. Ruddick, Newton, Mass., assignor to United States Electric Signal Company, Portland, Me. Filed May 23, 1908. A block system consists of a normally closed circuit throughout the block and means for sending a signaling current by opening this circuit and connecting one point thereof to the source of current and another point to ground.

903,791. DOUBLE-POLE ELECTRIC CIRCUIT-BREAKER. William H. Scott, Norwich, England. Filed July 24, 1908. The sparking points of the switches are arranged in separate compartments so that flashing over from one to another is prevented.

903,796. ELECTRIC BLOCK-SIGNAL SYSTEM. Paul J. Simmen, Oakland, Cal. Filed January 28, 1907. Sections of one rail of the track are connected only by inductive resistances to permit the passage of direct current and prevent the passage of alternating current.

903,799. STORAGE BATTERY. John L. Smith and Malcon O. Smith, Cleveland, Ohio. Filed July 20, 1908. The edges of the plates are carried by elastic non-conducting frames and a mud guard frame of non-elastic material is clämped between the plate-holding frames.

903,807. ADJUSTABLE SUPPORT FOR ELECTRIC WIRES. Albert W. Bensley, Pawtucket, R. I. Filed September 15, 1908. A support carries two insulators that can be adjusted to different angular positions.

903,811. RELAY FOR REINFORCING SOUND. Jens H. Christensen, Sövejen, Sölleröd, Denmark. Filed March 30, 1905. A telephone relay comprises a diaphragm, a pendulum adjacent thereto and having a contact bearing against it, the pendulum being supported by jewel bearings consisting of a mercury contact for conducting current through the pendulum.

903,812. ELECTRICAL PROTECTIVE APPARATUS. Frank B. Cook, Chicago, Ill. Filed March 8, 1906. A thermal protector for a telephone circuit has a number of conducting rods associated therewith.

903,813. CONTACTLESS THERMAL PROTECTOR. Frank B. Cook, Chicago, Ill. Original application filed July 28, 1905. Divided and this application filed April 12, 1907. This is a modification of the above.

REISSUE.

12,878. SUPPORT FOR POLE CROSS-ARMS. Edward C. Short, St. Paul, Minn., assignor to Steel Gain Manufacturing Company, Chicago, Ill. Filed June 13, 1906. Original No. 804,630, dated November 1, 1905. A curved post plate and a cross-arm plate with flanges are connected by tongues, and a bolt clamps the plates between the cross-arm and the post.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired November 17, 1908:

463,154. ELECTRIC ARC LAMP. William Jandus, Cleveland, Ohio.

463,174. ARMATURE FOR DYNAMOS OR ELECTRIC MOTORS. B. D. Southard, Chicago, Ill.

463,188. TELEPHONY. J. W. Gibboney, Lynn, Mass.

463,192. ELECTROMAGNETIC SWITCH. C. H. Herrick, Winchester, and W. M. Rand, Boston, Mass.

463,198. ELECTRIC STOP MECHANISM. L. Mellett, Somerville, Mass.

463,207. TELEPHONIC RELAY. E. E. Weaver, Philadelphia, Pa.

463,242. DYNAMO-ELECTRIC MACHINE. M. C. Burt, Chicago, Ill.

463,247 and 463,248. GALVANIC BATTERIES. W. A. Crowdus, Memphis, Tenn.

463,257. ICE-BREAKER AND ELECTRIC-CURRENT TRANSMITTER. C. Smith, Wilkesbarre, Pa.

463,297. ELECTRIC LOCK. F. H. Starrett, Clinton, Mich.

463,298. THERMO CIRCUIT CLOSER FOR ELECTRIC FIRE-ALARMS. J. Wrigley and G. Chambers, Paterson, N. J.

463,311. ELECTRIC SWITCH. E. J. Bagnall, St. Louis, Mo.

463,314. ALTERNATING OR PULSATING CURRENT MOTOR. L. Gutmann, Pittsburg, Pa.

463,315. POWER-STORING MECHANISM FOR ELECTRIC LOCOMOTIVES. J. A. Hochett, Stirling, Kan.

463,340. FIRE-ALARM TELEGRAPH REPEATER. G. M. Stevens, Cambridge, Mass.

463,356. ELECTRIC LOCOMOTIVE. S. H. Short, Cleveland, Ohio.

463,384. ELECTRIC CIGAR-LIGHTING APPARATUS. W. W. Foster, Boston, Mass.

463,395. ELECTRIC TRAIN SIGNAL. J. B. Strauss, Cincinnati, Ohio.

463,396. ELECTRIC SWITCH. A. Swan, Orange, N. J.

463,420. COUPLING FOR ELECTRIC WIRES. F. X. Gartland, Philadelphia, Pa.

463,428. TELEGRAPH SOUNDER. J. Maret, Mount Vernon, Ky.

463,486. PROCESS OF WELDING METALS ELECTRICALLY. C. L. Coffin, Detroit, Mich.

463,487. ELECTRIC WELDING OR WORKING OF METALS. C. L. Coffin, Detroit, Mich.

463,512. ELECTRICAL CONDUCTOR. P. H. Holmes, Gardiner, Me.

463,545. MULTIPLE SWITCHBOARD. F. A. Pickernell, Newark, N. J.

463,558. APPARATUS FOR MEASURING AND RECORDING ELECTRIC CURRENTS. William Thompson, Glasgow, Scotland.

ELECTRICAL REVIEW
AND
WESTERN ELECTRICIAN

VOL. LIII. No. 22. CHICAGO, SATURDAY, NOVEMBER 28, 1908. ISSUED WEEKLY

BY THE
ELECTRICAL REVIEW PUBLISHING COMPANY.
CHARLES W. PRICE, President.
STEPHEN H. GODDARD, Vice-President. H. S. TUTHILL, Secretary.
PHILIP S. DODD, Manager. C. W. FORBRICH, Assistant Treasurer.

PUBLICATION OFFICE: 204 DEARBORN STREET, CHICAGO.

The present publication comprises: ELECTRICAL REVIEW, VOL. LIII, No. 22; WESTERN ELECTRICIAN, VOL. XLIII, No. 22.

EASTERN DEPARTMENT . . . . 13 Park Row, New York.

One Year, United States	$3.00
One Year, Canada	4.00
One Year, Foreign Countries	6.00
Single Copy, 10 cents. Back numbers, beyond one month, each	.25

Changes of address reaching this office later than Monday cannot be made until the issue next following.

Application made for entry at the Post Office at Chicago as second-class matter under the Act of March 3, 1879.

CONTENTS.

RAILWAY ACCIDENTS.

For some time there has been a conscientious effort upon the part of railways to eliminate the possibility of fatal accidents both to employes and others liable to injury in the ordinary conduct of railway systems. For the perfection of safety devices railway corporations have expended large amounts of money, and the efforts of inventors have been encouraged in order to procure the greatest measure of safety to those coming in contact with the vicissitudes of railway operation. The heavy penalties exacted in case of injury, and the readiness with which the ordinary jury has sought to mulct the transportation company, have been sternly contributory to the attitude of mind which has prompted the safeguarding of human life. Even when the railroad corporation has done all that seems reasonable to protect others from injury there has come about recently a new idea as to what constitutes contributory negligence on the part of one injured. Notwithstanding ordinary safeguards, such as block signals, train annunciators and gated crossings, it has been held in several important suits at issue that the loss of one's life is too great a penalty to pay for ordinary negligence, and that the railroad must see to it that the trespasser be not allowed to suffer by reason of his well-proven negligence.

The compilation of statistics by commissions in several states and by the Interstate Commerce Commission has thrown some actual light on the decreased number of accidents in recent years, and it is a cause for satisfaction to realize that in spite of increased traffic and more rigorous demands upon the railway systems in general, the number of accidents is decreasing. Bulletins of the Interstate Commerce Commission for the year ending June 30 show that during this period there was a total of 3,764 killed and 68,989 injured, a decrease in the total number of 1,236 killed and 3,297 injured, compared with the number reported for the same period a year ago. For the three months ending June 30 the total number of casualties was also lower.

Not only in this country does this condition obtain, but the same is true of the United Kingdom, for which statistics are at present available. According to the Board of Trade report on railway accidents in Great Britain last year, 120 passengers lost their lives on the railways, as against 166 in the preceding year. During 1907, 454 servants of railway companies or contractors lost their lives, and 5,813 were injured, as against 438 killed and 4,365 injured in 1906. While this shows an increase, it is only an apparent increase, owing to the new Board of Trade regulations, which list minor accidents involving only a day's absence from work, which were not reported in previous years.

ELECTRICAL DRIVING IN COTTON MILLS—TWO BRITISH VIEWS.

In a recent issue of the *Electrical Review,* of London, Mr. W. H. Booth takes issue with those engineers who have put forward what he considers extravagant claims as to the desirability of installing motor-drive in cotton mills, and speaks strongly against the adoption of direct-connected motors, and particularly individual driving. Comparing belt-drive with direct connection, Mr. Booth says that while it may be possible to start a frame more quickly than is done with a belt, it will perhaps be sufficient to say that the frame may be brought to full speed by belt quicker than it now is started, because the women "tenters" are paid on the piece system, and are aware that they may lose more by starting too quickly than by starting at a gentle acceleration. This seems to be a point which can hardly be considered a disadvantage in electrical driving. With properly constructed starters and with motors of the interpolar type, not only a gentle, but a very even, acceleration can be secured; and although it must be admitted that the cotton-spinning machines generally run continuously and at a constant speed, it is an advantage to have a driving device that will allow the speed to be changed, and will also permit the machine to run efficiently if more than one speed is desirable.

Mr. Booth claims that usually, when driving a ring frame by its own electric motor, it is necessary to make room for the motor by decreasing the length of the frame by several spindles. It is said that the greater output of yarn per spindle in a recent case investigated was more than counterbalanced by the reduced number of spindles. The better appearance, the advantage of the absence of belts, and the improved lighting facilities, are admitted. Even though the spindle output be increased, say, five per cent, he believes it is not worth while doing so if this entails an expenditure of seven per cent of the spindles cut away to make room for the separate motor.

In the same issue of our London contemporary there is an illustrated description of the electrical equipment in an English cotton mill. The identity of this installation is not revealed, but the following paragraph is of interest, remembering the criticisms made by Mr. Booth, and referred to above: "Fortunately, circumstances do arise occasionally when a really modern electrical drive appeals to the mill-owner, a case in point being a recently-built doubling shed erected by a well-known firm of fine cotton spinners and doublers. In this case electrical driving was only decided on after exhaustive tests had been carried out."

The illustrations show the spinners and doublers equipped with enclosed motors, with the switch gear attached to the ends of the frames. The absence of belting allows a fine wiring scheme to be carried out, and makes possible very good daylight and artificial illumination.

The shed contains fifty doubling frames and the necessary auxiliary machinery, each frame being driven by a twelve-horsepower motor. The textile operations dealt with necessitate a wide range of speed, and variable-speed, ball-bearing motors of the interpolar type have been installed. Speed variation is of special importance in this class of work, and the speed of any frame may be carried to the highest limit, according to the particular work being dealt with at the time.

It may be well to mention, in passing, that experience has already shown that the cost of running is so low that the proprietors are installing some thousands of additional spindles, to be driven from another 150-kilowatt generating set.

WIRELESS TELEPHONES FOR THE GOVERNMENT.

It is understood that the United States Navy Department is about to ask for bids for powerful wireless telephone apparatus, the specifications calling for devices capable of establishing reliable communication for distances of not less than 100 miles. It is intended to supersede, as far as practicable, the wireless telegraph, and make communication by wireless telephone as complete as possible between certain to-be-established points of rendezvous.

The great amount of attention which has been paid by the Government to the development of wireless telegraph and wireless telephone apparatus is in marked contrast to its attitude when Morse was looking for governmental help to run his Washington-Baltimore line fifty years ago. At that time meager appropriations were squeezed out by painful efforts and great persistence on the part of this hardy inventor. Today not only is the Government making goodly appropriations for the development of wireless telephone and telegraph apparatus by private individuals, but the engineering corps is bending its best efforts to the improvement of the material turned over by private investigators. Some of the best work in wireless development has been done by the Government engineers, and to them is due the credit for establishing all of our most recent records for both distance and quality of service.

The success of the initial equipment of de Forest wireless telephone instruments on board United States men-of-war has helped materially to establish the advantages of the wireless telephone as a means of ready communication between ships at sea and between ships and nearby shore stations. There seems to be no reason why greater ranges of distance cannot be covered by improved apparatus, and a number of investigators have apparently pointed out the way in which this can be readily accomplished. Indeed, it seems that with the remodeling of present-day apparatus, particularly in reconstructing the telephone transmitter to work reliably at higher potentials, and to withstand the heating effects introduced by the high-frequency oscillations superimposed upon the natural vibrations of the transmitter diaphragm, a great step in advance will be taken, and we are promised that this consummation is near at hand. It is unfortunate that at present the field of wireless telephony is more or less clouded by litigation and the rival claims of several bona-fide and conscientious investigators. This, however, will hardly retard the progress of development, and the attitude of the Government, whether it work to the benefit of the individual investigator or not, will hasten the day when at least near-perfection shall be attained.

DEPRECIATION AND REPAIRS.

Depreciation amounted to 4.09 per cent, and repairs to 6.06 per cent annually, during sixteen and one-half years, on an average, according to the statement of one electric-lighting company.

This statement was made several years ago, at a public hearing on the question of further stock issues, as bearing on the value of the electric plant, and was not controverted.

It is not the purpose here to either indorse or criticize the accounts of this company, and no investigation has been made that would warrant either course, but the figures are given for what they are worth. While they may be entirely correct for the electric plant in question, it is of course very uncertain how far they would apply in any other case.

At the time that the statement of its repair and depreciation accounts was made, the electric company had a steam-driven generating plant of about 1,100 kilowatts capacity, made up of both direct and alternating-current apparatus. During the period of sixteen and one-half years to which the repair and depreciation accounts apply, the electric plant had gradually grown from a capacity of about 200 kilowatts.

Taking the entire series of years, the average investment of the company was put at $168,895, in each year, while the total depreciation was given as $114,011, and the entire amount expended for repairs was $138,741. With these amounts as a basis, the average annual depreciation of the plant was put at $6,909, and the average amount annually expended for repairs was $8,408. From these figures came the above conclusion of 4.09 per cent on investment for annual depreciation, and 6.06 per cent for repairs.

Perhaps the most interesting part of the accounts, as stated, was the separate items of repairs, which were as follows: Repairs, steam plant, $42,408.11; repairs, electric plant, $18,152.81; repairs, lines and transformers, $70,413.09; repairs, station building, $7,767.17; total repairs, sixteen and one-half years, $138,741.18.

As was to be expected, the items for steam-plant repairs and for line and transformer repairs are large, and the size of the steam-plant item brings out in a striking way the great change that has taken place in motive-power equipment since electric stations were started some twenty years ago with simple non-condensing engines, often in sizes as small as 100 horsepower.

Stated in percentages, the steam plant absorbed 30.5, the electric plant thirteen, lines and transformers 50.7, and the station buildings 5.6 per cent of the repair charges.

At the middle of the period of sixteen and one-half years covered by the depreciation and repair accounts, the generating capacity of the electric station amounted to very nearly 800 kilowatts, and if this be taken to be the average capacity for the period, the average annnual depreciation appears to have been $8.63 per kilowatt of generators, for the entire plant.

On a like basis, the total average repairs amount to $9.26 yearly, per kilowatt of generator capacity, for the entire electric system.

THE WESTINGHOUSE PLAN.

The modified reorganization plan of the Readjustment Committee of the Westinghouse Electric and Manufacturing Company, which has been under consideration for several months, has been declared operative, and apparently all that remains before the discharge of the receivers is the carrying out of the formalities connected with the issuing of the new stock provided for, and, of course, other details which, now that the fundamentals are ready for promulgation and inauguration, will be incidental to the course of reconstruction. By the end of this week the stockholders will have met in Pittsburg to elect new directors and ratify the various measures necessary to the completion of the reorganization plan. Undoubtedly, the merchandise creditors and the bankers who have been co-operating for the purpose of reorganization will have a powerful voice in the affairs of the company, and with this end in view the directorate will be increased from twelve to sixteen, divided into four classes, serving from one to four years each.

Four factors have combined to win success for the reorganization plan, and this success has been won against great odds. These factors have been the loyalty of stockholders in subscribing for $6,000,000 worth of stock at par when it was selling at hardly half that price in the open market; the liberal co-operation of merchandise creditors in agreeing to take $4,000,000 of stock at par in settlement of that amount of claims held against the company; the participation of bankers holding $7,900,000 short-time notes of the company in coming to the front with eighty-five per cent of the total amount and taking securities in payment of their obligations. To these factors must be added that which has been most important and inspiring: the personal enthusiasm and optimism of George Westinghouse, president of the company.

THE CHICAGO ELECTRICAL SHOW.

The fourth annual Chicago Electrical Show will be held under the auspices of the Electrical Trades Exposition Company at the Coliseum, Chicago, from January 16 to January 30. Present indications point to even greater success than has attended the efforts of those responsible for the show on the three former occasions, when expositions of record-breaking proportions, both in number of attendants and general interest, were conducted. Last year, although in the midst of a financial disturbance of considerable magnitude, stockholders and exhibitors alike were well satisfied with the money put into this enterprise. This year eighty per cent of the exhibit space has now been spoken for, and it is expected that by the middle of December all the available allotments will have been taken up.

The same excellent decorative features, with a possible enhancement of lighting effects, will obtain at the coming show, and it is purposed to increase the number of working demonstrations and render the exposition, if possible, more attractive than ever to the general public, at the same time making it particularly and significantly an electrical exhibition for the benefit of the electrical industry.

PUBLIC SERVICE CASES.

BY ALTON D. ADAMS, LL.B.

LEGAL RATES—DEPRECIATION AS EXPENSE.

A California statute authorizes county supervisors to fix the maximum rates at which water is sold for irrigation and other purposes, so that the net income upon the value of the property used in furnishing water will be not less than six nor more than eighteen per cent annually. Before fixing the rates the supervisors are required to estimate the value of the property used in furnishing water and the reasonable expenses of operation, including repairs of the water system.

The system of an irrigation company supplies water in the counties of Fresno, Merced and Stanislaus, California, and the supervisors of these counties have fixed the maximum rates for irrigation at eighty-five cents per acre per annum in Fresno County, $1.65 per acre per annum in Merced County, and $1.50 per acre per annum in Stanislaus County. Head works of the irrigation canal are in Fresno County, and after passing through Fresno County the canal runs through Merced County and thence into Stanislaus County. This location of the irrigation system is supposed to be the reason for the higher rate fixed for Merced County than for Fresno County, because of the greater expense of delivering water in Merced County, and the same reasoning would lead to a still higher rate in Stanislaus County instead of the lower rate of $1.50.

The irrigation company asks the court for an injunction to prevent the enforcement of the rates fixed in the three counties, on the ground that these rates will not provide net earnings of at least six per cent on the value of the irrigation system, as provided by statute, and also on the ground that the enforcement of these rates will take its property without due process of law.

According to the estimates of the supervisors of the three counties named the total value of the irrigation system in these counties is $1,201,706.32, and the reasonable annual expense of operating the system is $93,750. On the basis of the number of acres actually irrigated in the three counties, and at the rates fixed by the supervisors, the gross earnings of the irrigation system would amount to $137,873.65 per annum, so that the net earnings would be $44,123.65, or 3.67 per cent on the value of the property as estimated by the supervisors. According to the estimate of an engineer, the value of the physical property in the irrigation system is $1,166,904.53, and the books of the company show an operating expense of $86,437.50 during 1906, giving net earnings of $51,436.15, or 4.4 per cent on this physical valuation, with gross earnings at $137,873.65.

This net earning of 4.4 per cent on the value of the physical property is obviously less than the six per cent provided by statute, and the court said:

"Disregarding the provision of the statute, there is no evidence before the court that an income of 4.4 per cent per annum for this kind of property is reasonable and just."

Besides the physical value of the irrigation system there was the right to divert 760 cubic feet of water per second from the San Joaquin River, which was estimated by the company to have a value of $760,000, but the value of this right was not considered by the court in reaching its decision, but was reserved for future consideration. This right to divert water is in the nature of a franchise, and as to it the court said:

"While this right is undoubtedly of value, it may not be a value upon which ultimately complainant may be given a return under the law."

The estimate of the supervisors as to the value of the irrigation system was based on the present prices of materials, less physical depreciation, and as to this the court said:

"If a deduction is to be made from the value of the plant on this account, then an allowance should be made for such deduction and added to the annual income to enable the complainant to renew and reconstruct, so as to preserve the integrity of the plant."

A temporary injunction was granted pending the final hearing against enforcement of the rates fixed by the supervisors.

San Joaquin and Kings River Canal and Irrigation Company versus Stanislaus County, 163 Federal Reporter 567, United States Circuit Court.

The Waterpowers of Sweden, Norway and Switzerland.

An address was delivered recently by Eduard Engelmann, Austrian state railway superintendent. In view of the intended erection of electric power stations by the Government for the operation of railways in the Austrian Alps, the modern waterpower installations and electric traction systems in Scandinavia and Switzerland were examined by the author. The Brennan mono-rail system was also investigated. The extraordinary advances in turbine construction have been accompanied by the exploitation of waterpowers in Sweden and Norway on a large scale, and a mighty movement is afoot there to adapt the antiquated water laws to the new conditions. The Government is aiding the development in every possible manner and has for itself secured sufficient waterpower to operate the most important railways. According to recent investigations the total waterpowers of Sweden are estimated at ten million horsepower, those of Norway at twenty-eight million horsepower, and those of Finland at four million horsepower. About ten million horsepower could be utilized in the near future. It may be stated that the waterpowers of France and Italy are estimated at three to four million horsepower in each country, and those of Switzerland at one million horsepower, and in none of these countries are the conditions for regulating the water courses so favorable as in Scandinavia, where over four million horsepower are available without regulation. At present there are in operation or under construction plants of a capacity of 500,000 horsepower in the three countries named. It is estimated that by the exploitation of some further million horsepower the imports of coal, iron, fertilizers and other commodities will be so greatly reduced that the present condition will be reversed and the exports will exceed the imports by some twenty million kroner. The cost of the electric generating stations without transmission lines is estimated to be from 250 to 300 kroner per electric horsepower in the south of Sweden and 150 to 300 in the North and 140 to 200 kroner in Norway.

Independent Telephone Convention.

The annual convention of the International Independent Telephone Association will be held at the Auditorium Hotel, Chicago, on December 1, 2 and 3. Sessions will be held in the morning and afternoon of each day for reading and discussion of practical papers. The banquet will be held on Wednesday evening. The manufacturers of telephone supplies and kindred apparatus are co-operating with the association, and a number of comprehensive exhibits will be placed in various rooms, adjacent to convention headquarters.

CONDENSERS.

BY S. K. PATTERSON.

The general use of condensing engines has led to the development of a branch of engineering connected with the construction and operation of condensers, and the knowledge in this field is nowhere near as general and complete as it should be, considering the importance of the subject. Thus condensers consist of a number of different types with different theoretical and mechanical efficiencies and different costs of installations. Some types are only used in special service and others are especially fitted for special types of engines. The various difficulties that are encountered in the operation of a condenser and the maintenance of the vacuum have been more or less satisfactorily met in a number of ways, but each of these possesses disadvantages, and in the selection of an average condensing installation the various advantages and disadvantages of each type must be considered and a selection made with this knowledge.

Thus condensers at the present time can be divided into two general classes, jet and surface condensers. Again they can be divided, with equal propriety, according to the maintenance of the vacuum by natural or mechanical means. A number of other divisions exist, but these are of minor importance, as will become apparent in the further development of the subject.

The general theory of condensers is well known. By the maintenance of a vacuum at the exhaust port of the steam-engine cylinder and the condensation of the steam at this point with a rapidity equal or superior to that of its entrance, the advantage of an additional pressure equal to the normal air pressure is obtainable on the piston of the steam engine. The great variability of efficiency of the modern turbine with that of the connected condenser is a fact well-known, and the importance of high vacuum and satisfactory condensation in this field cannot be overestimated. The increase in efficiency due to diminution in steam consumption, for the production of a given amount of power or due, on the other hand, to increased power from a given installation, ranges from fifteen to, in some cases, nearly forty per cent, depending upon the nature of the unit and the efficiency of the condensing device. That condensing machinery has reached its maximum efficiency is a conclusion that can scarcely be made but undoubtedly great steps in advance have been made, as is at once apparent from a study of their relative efficiencies, increased simplicity of construction and of their operative features, many of which only become apparent as the result of continuous operation of the condenser itself under all conditions of load and water variability.

Now, in order to get a clear realization of some of the difficulties actually met with in operation and design of condensers a few details not ordinarily considered may be casually mentioned. In order to produce condensation cold water must be circulated through the vacuum into which the steam comes, and the air carried in by this and by the steam must be removed for the maintenance of the vacuum. The circulating water system must be accomplished through a closed water seal against the atmospheric pressure and this water undergoes, during circuit, comparatively wide variations in regard to pressure and temperature. Heated by the steam in the presence of the high vacuum, where the boiling point of the water is extremely low, the temperature of the water may rise to a sufficient extent to produce spontaneous boiling. Under these circumstances the operation of the condenser for condensing purposes and the increased development of power practically ceases. Again, the air must be removed for the maintenance of the vacuum, which must be held comparatively high, and this can be accomplished most efficiently by the use of vacuum pumps. If boiling occurs the rubber gaskets or packing in the vacuum pump are apt to be burnt out, and flooding with steam or water is an occurrence under many conditions, with resulting deterioration to many of the parts and inconvenience and delay in restarting the condensing feature. Again, many large steam units are so installed today that they do not possess sufficient power if they do not maintain the condensing feature in conjunction with their operation. Thus the temporary withdrawal of the condenser from active service, due to any of these causes, often results in actual shutdown of the plant itself. This feature was formerly more or less present in such installations as rolling mills, etc., where the load was excessive and the duty on the condenser variable and often excessive.

Now, a few words in regard to the constructive details of the various types. The vacuum chamber in connection with the exhaust port of the steam engine is maintained in contact with atmospheric pressure by the use of two columns of water approximately thirty feet high, in actual operation. These columns are identical in theory and operation to the ordinary mercury barometer, and a water circulation is produced merely by pumping the water in one column over the intervening height, whereupon its withdrawal in the other column by gravity is effected automatically. The position of the pump in this device is a very variable factor. It may be used directly to lift the water into the condenser and the outflow accomplished by means of gravity as mentioned. It may be used, on the other hand, to force the water down and out in one of the columns, thus balancing the air pressure directly by mechanical means. The height of the water column under these circumstances is much reduced, and its necessity in others often completely eliminated. Again, this thirty-foot vertical height condenser column may occupy various positions with respect to the surface of the earth and the available water supply. If sunken the pump may be used to remove the water from the hot well, with the maintenance of a fixed level at this point and the consequent automatic flow of water through the condenser to supply the deficit. By the use of a pump injecting water into the vacuum the velocity of this water can be used to assist the force of gravity in its removal, and in many of the jet-condenser types this velocity of the water entering into the vacuum, and produced by mechanical or natural means, is often used to assist in the evacuation of both the water and air from the condenser chamber.

This variability of design and mechanism to produce identical conditions has resulted in a considerable variation in size and design of the average condenser. The jet condenser in which water is injected through a fine spray, and then carried off by means of a positive pressure or rotary pump, is the simplest in design and comparatively small in construction. It can be readily attached to the steam engine in any position, but possesses various limitations on efficiency due to the low vacuum maintained with the small ejection of the air by this means. It can exist in very small units in this type, and even in the large ones its size appears very small in comparison to the types using thirty-foot vertical water columns for the maintenance of the vacuum and the operation of an air pump for the removal of the air. The types using the air pump and the water column, while probably not so common in small installations, possess undoubtedly an increased efficiency over the other type and exist in some cases in comparatively enormous units, single condensers for the condensation of the steam from units as high as 24,000 horsepower being not uncommon.

These various types of condensers are used in various situations and under various conditions of special advantage for each type. Thus, the barometric condenser or condenser using a large water column for a seal against the atmospheric pressure is practically impossible of utilization on shipboard. Some type of the jet condenser utilizing either a simple spray with the velocity of the water itself for the removal of the air or possessing, further, an injector addition for the further removal and entanglement of the air in the outgoing stream is common here. In large stationary plants, where the space is available, the other type is undoubtedly more efficient and satisfactory.

When the water supply is limited, various types of condensers, run in conjunction with cooling towers, which may or may not be an actual part of the mechanism, aften possess special advantages. In these the water after being heated by the steam is in turn cooled by evaporation into the air in the cooling tower. The loss by evaporation is less than the supply due to steam condensation, since the latent heats of evaporation and condensation in the two cases are about identical and the water is cooled in addition by conduction to the air. Hence, in this type a slight addition of water is continually made from the steam, which more than counterbalances the loss to the condenser water in the cooling tower, so that no water supply is necessary here. With impure or saline water the surface condenser is necessary. The boiler water must be maintained pure and the water resulting from steam condensation kept separate from the condenser water. This is accomplished by the use of a device equivalent to the ordinary tubular boiler or shell cooler such as is used in refrigeration. The vacuum is maintained on one side of the tubes and the cold water circulated on the other. If this water of condensation is pumped directly through the reheater to the boiler, no necessity for a water seal against atmospheric pressure is necessary in this part of the mechanism. The circulation of the cold water in the other half of the condenser is not limited in operation by the maintenance of a vacuum and much higher temperatures can be acquired by this water without affecting seriously the operation of the condenser. Thus the closed or surface type of condenser possesses many advantages in regard to economy of water consumption, since a given quantity of the water may be made much hotter. However, the rapidity of heat transfer in this type is nowhere near as great as in the jet or barometric condenser, and much larger surfaces must be used to perform the same duty in steam condensation. A given condenser, if of the surface type, possesses less ability to take care of a steam overload but is practically the only type available when limitations are in force on account of water impurity.

A number of additional features of interest to engineers, and not commonly considered, enter in the operation or maintenance of a condenser. A centrifugal pump is often extremely unsatisfactory in the production of water circulation in a condenser of the barometric type. The output of such a pump varies greatly with the air pressure and its action in this regard proves a great disadvantage. When additional steam enters the condenser chamber the water supply falls off instead of increasing with this type. Extreme heating of the water may result, with consequent boiling and a breaking of the vacuum. A positive pressure pump of either a rotary or reciprocal type is much superior. A periodic steam overload, again, may often result in a periodic surging of the water column up and down with ultimate breaking of this and the destruction of the vacuum, and suitable valves must be installed for the prevention of this. In the Weiss type of barometric condenser boiling of the water is prevented by an ingenious device. When the vacuum falls, due to an overload of steam which may cause excessive heating, or when boiling of the circulating water occurs, an automatic valve allows a small quantity of air to enter the vacuum chamber. This lowers the vacuum, raises the boiling point, and stops the boiling of the condenser water. The vacuum is gradually strengthened by the operation of the vacuum pump, and the condenser goes on without stoppage and only a slight diminution in efficiency with this occurrence. With many of the other types boiling of the water results in absolute shut-down. The Alberger condenser possesses two distinct advantages, in turn, over its competitor. The spray valve is maintained in position by a spring which automatically accommodates itself to the quantity of water entering the condenser head. No attention need be paid to the regulation of this valve, as exists in other types, and the water supply is regulated only by the speed of the pump. Its other advantage consists in the very complete and satisfactory device for the separation of the air and moisture in the chamber immediately above the spray cone. Much drier air is furnished the vacuum pump by this device than can be obtained by the other types. Consequently the efficiency in the operation of the vacuum pump is much increased in this development. The steam and water entering in the same direction, assist each other's flow in the downspout. When a counter-current action is attempted with these two ingredients a more complete transfer of heat for a given quantity of water is apt to occur, but steam overloads tend to diminish the water supply on account of the variation in velocity and pressure. Water enters a vacuum under normal air pressure with a velocity of forty-seven feet per second, and steam enters the same vacuum, under normal conditions of operation, at a speed of about 1,900 feet a second. This high velocity, and its utilization in the maintenance of water flow through the condenser, is undoubtedly partially responsible for the great efficiency of this type of condensing apparatus. Practically all makers of the barometric type of condensers make jet condensers, using a pump directly as well. The field is so divided that all types of condensers serve a distinct and separate purpose in special fields in which other types cannot compete with any degree of satisfaction. The necessity of having large pipes with rapid flow and a high capacity in turbine condensers is well known, and the result is that specialization in this field is going on with considerable rapidity, and new developments are of almost daily occurrence.

Madame Curie for Paris Chair of Physics.

Mme. Curie, who jointly with her husband, the late Professor Curie, discovered radium, has been appointed Chief Professor of Physics in the Faculty of Science at Paris University. This is a recognition, well earned, which will be appreciated and commended by all interested in this remarkable woman's work in pure and applied science.

An Inductor Alternator as a Telephone Relay.

It has sometimes been proposed to employ as telephone relays direct-current dynamos having the field winding in the primary circuit and the armature winding in the secondary circuit, so as to produce in the latter currents of the same frequency and wave form as the currents in the primary circuit. The operation of such devices is interfered with by the disturbing effect of the collecting devices, and no relay of this type is in commercial use.

An invention of Ernst F. W. Alexanderson of Schenectady, N. Y., has been recently patented and assigned to the General Electric Company, and consists in using a high-frequency inductor alternator as a telephone relay. In such a machine both the field winding and the armature winding are stationary; the only moving part is the inductor, which is magnetized by the field winding. The inductor is designed so that its natural frequency, which is determined by the number of its poles and its speed, is very high compared with the frequency of the currents in a telephone circuit, so that each wave or pulsation of the telephone current corresponds to a large number of the alternations due to the movement of the inductor. The variation of the current in the primary circuit in which the field winding is connected does not change the frequency of the armature currents, but does change the amplitude of these currents; and if their frequency is above that of an audible note, the effect on a telephone receiver is simply that of the variation in amplitude, which corresponds to the variation of current in the primary circuit.

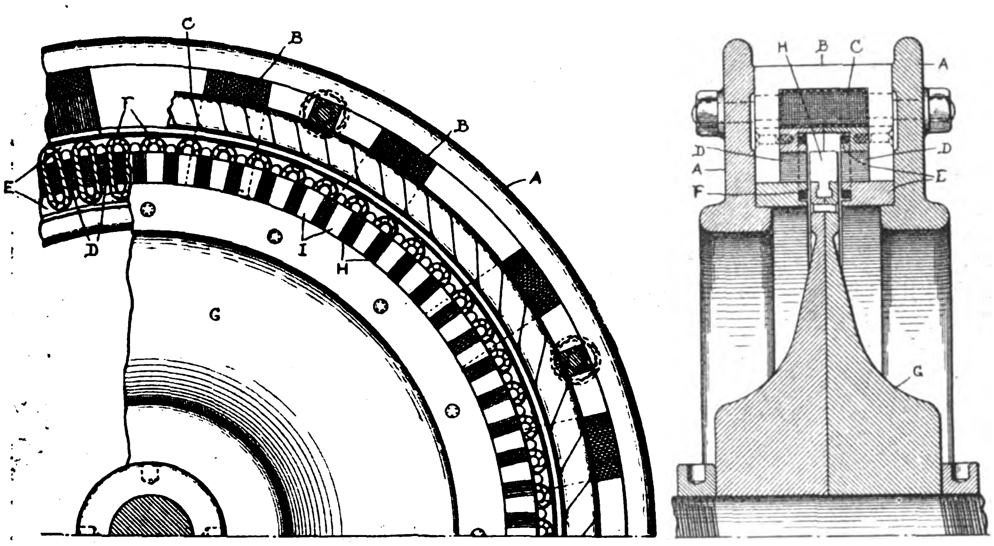
In Fig. 1 is shown a partial end view, partly in cross-section, of an inductor alternator designed in accordance with the invention for use in a telephone relay; Fig. 2 shows a side elevation of the same. A A represent end frames, between which the magnetic circuit of the stator is secured. This comprises bundles of laminations B B, arranged radially and surrounding the field coil C, which extends circumferentially around the machine, and the laminations D, which extend in a circumferential direction, and form with the laminations B a nearly closed magnetic circuit for the field winding C. The laminations are supported and spaced apart by non-magnetic spacing blocks E. The air-gap in the magnetic circuit of the stator has its opposite faces lying in adjacent radial planes; and in slots on these faces are placed the coils F of the armature winding.

The inductor G is shaped for maximum strength with respect to centrifugal strains, in order that it may be operated at very high speeds. It carries at its rim magnetic poles H formed of small bundles of laminations, which revolve between the opposite faces of the magnetic circuit of the stator. Non-magnetic blocks I are placed between the magnetic poles H, in order to strengthen the poles mechanically, and to decrease winding losses.

The field winding C is connected in circuit with a source of current and a telephone transmitter, either directly or through a transformer, according to common telephone practice. The armature winding F is connected in circuit with a suitable receiving device, which may comprise a liquid receiver of a type well known in wireless telegraphy, and a telephone receiver and a source of current connected in shunt to the liquid receiver; the principle of this arrangement being that the high-frequency alternations impressed on the liquid receiver vary its resistance, and the resistance variations result in current variations in the telephone receiver, which are audible therein.

The principle of operation of this telephone relay is as follows: The currents in the armature or transmitter circuit vary in amount when a message is being transmitted, and this variation is both in amplitude and frequency corresponding to the sound waves. The currents induced in the armature winding are of a high frequency, compared with the currents in the primary circuit. The frequency of these currents is not affected by currents in the primary circuit, but their amplitude is affected and varies in proportion to the primary current. The frequency of the armature currents is so high as to be inaudible in a telephone receiver, but the variation in amplitude produces audible sounds in the receiver of similar quality to, but of greater amount than, those that would be heard if a telephone receiver were substituted for the field winding of the alternator in the primary circuit.

It has already been stated that the stator laminations D extend circumferentially, while the laminations B, forming the greater part of the magnetic circuit, extend radially. The purpose of the circumferential arrangement of the laminations D is to localize the flux variations due to the high-frequency armature currents. Since the laminations in which the armature coils are placed extend circumferentially, the flux due to the currents in these coils can close itself directly around the coils, without producing any variations in the main part of the magnetic circuit.



FIGS. 1 AND 2.—PARTIAL END VIEW AND CROSS-SECTION OF INDUCTOR ALTERNATOR.

Projected Bank for Electrical Undertakings.

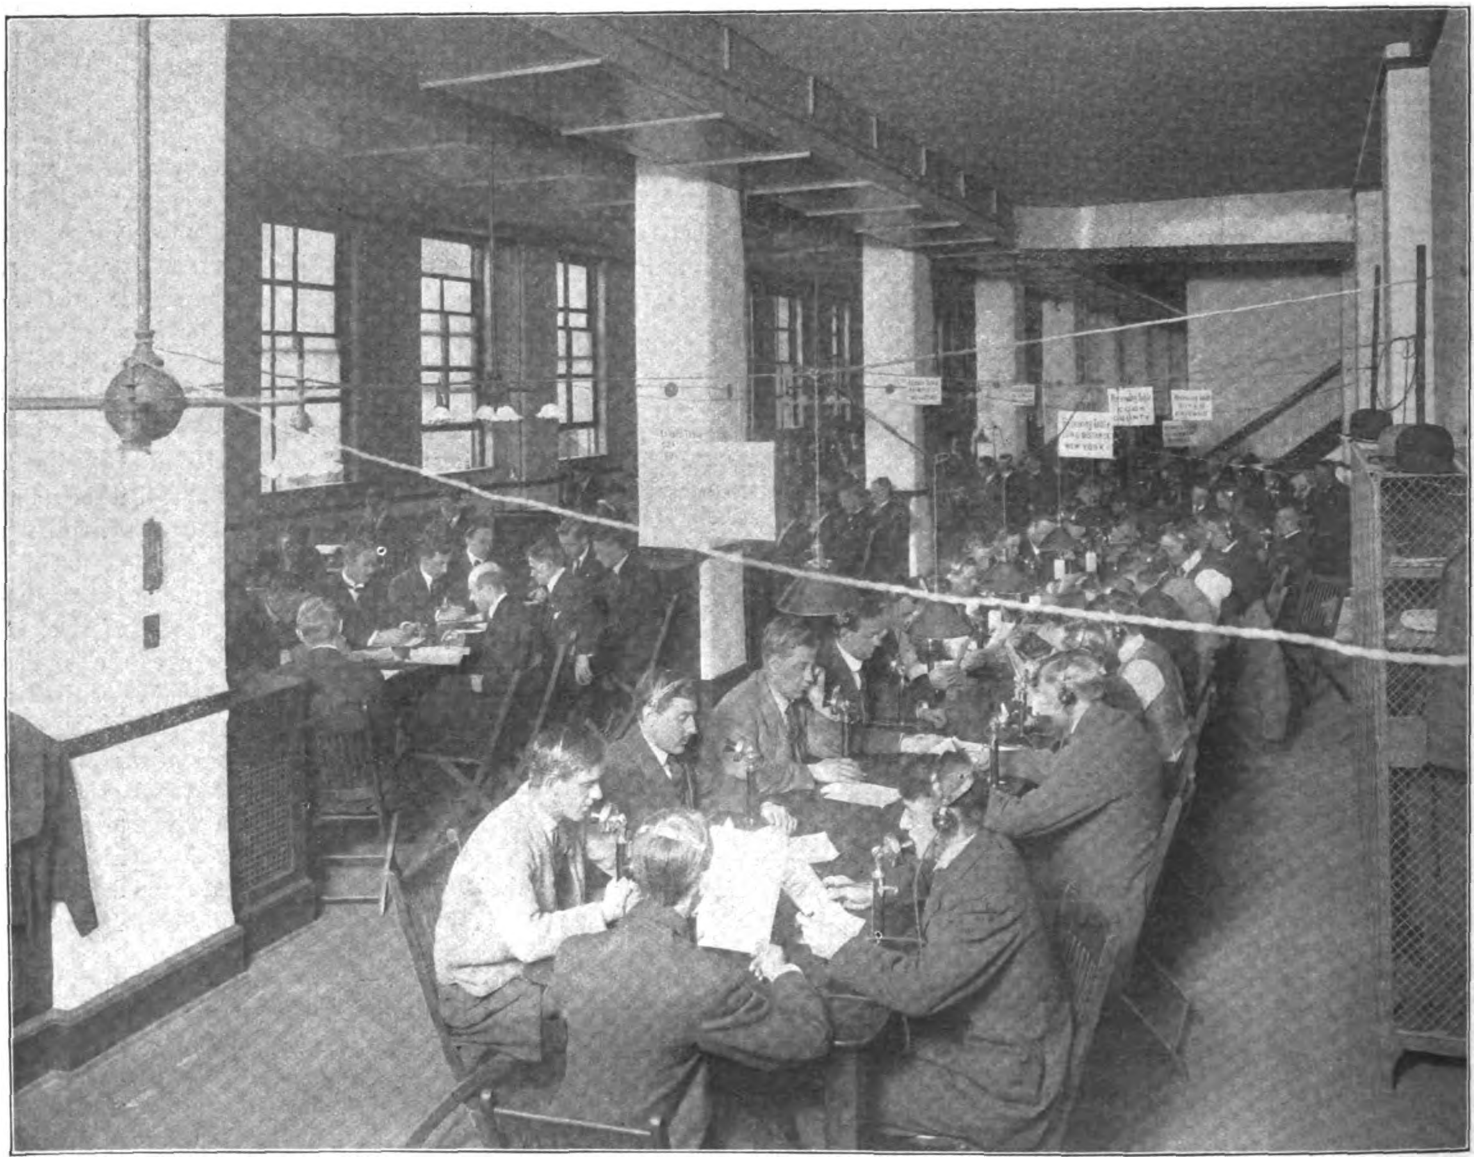
It is announced in the *Frankfurt Gazette* that some of the great German electrical firms propose to form a special banking institution to finance electrical undertakings. It is spoken of as the "Electro-bank." The capital is to be $7,500,000, with a large note issue in the form of bonds carrying interest at the rate of four and one-half per cent. The two companies mainly concerned in the new bank are the Allgemeine Elektrizitäts-Gesellschaft and the Siemens-Schuckert Works. It is understood that only large contracts for government and municipal bodies will be dealt with by the new financial institution, and it is doubtful if proposals of an industrial character will be entertained.

Election Returns by Telephone in Chicago.

Preparations throughout the country for transmitting election returns by telephone were more elaborate this year than ever before. The American Telephone and Telegraph Company, operating its extensive long-distance service, established headquarters in each of the states reached by its lines, comprising essentially all of the country east of the Rocky Mountains. At these headquarters the state returns were gathered and transmitted directly to New York. The returns were there compiled and sent out again all over the country by the long-distance wires, in the form of brief bulletins, telling the principal features of the results on an up-to-the-minute basis. As the information was in general confined to a few of the principal candidates, the results were quickly compiled and reached the entire country in a shorter time, doubtless, than any similar bulletins ever sent out in this or any other way.

In the large cities special arrangements had been made to gather the returns quickly and transmit them by telephone. In Chicago, by arrangement with the City Press Association, returns from the city precincts were telephoned to the Main Exchange compiling office immediately they were received at the City Hall. Similar means were provided for gathering news in the various counties around Chicago, and these returns were made up into brief bulletins for local distribution and also transmitted to New York.

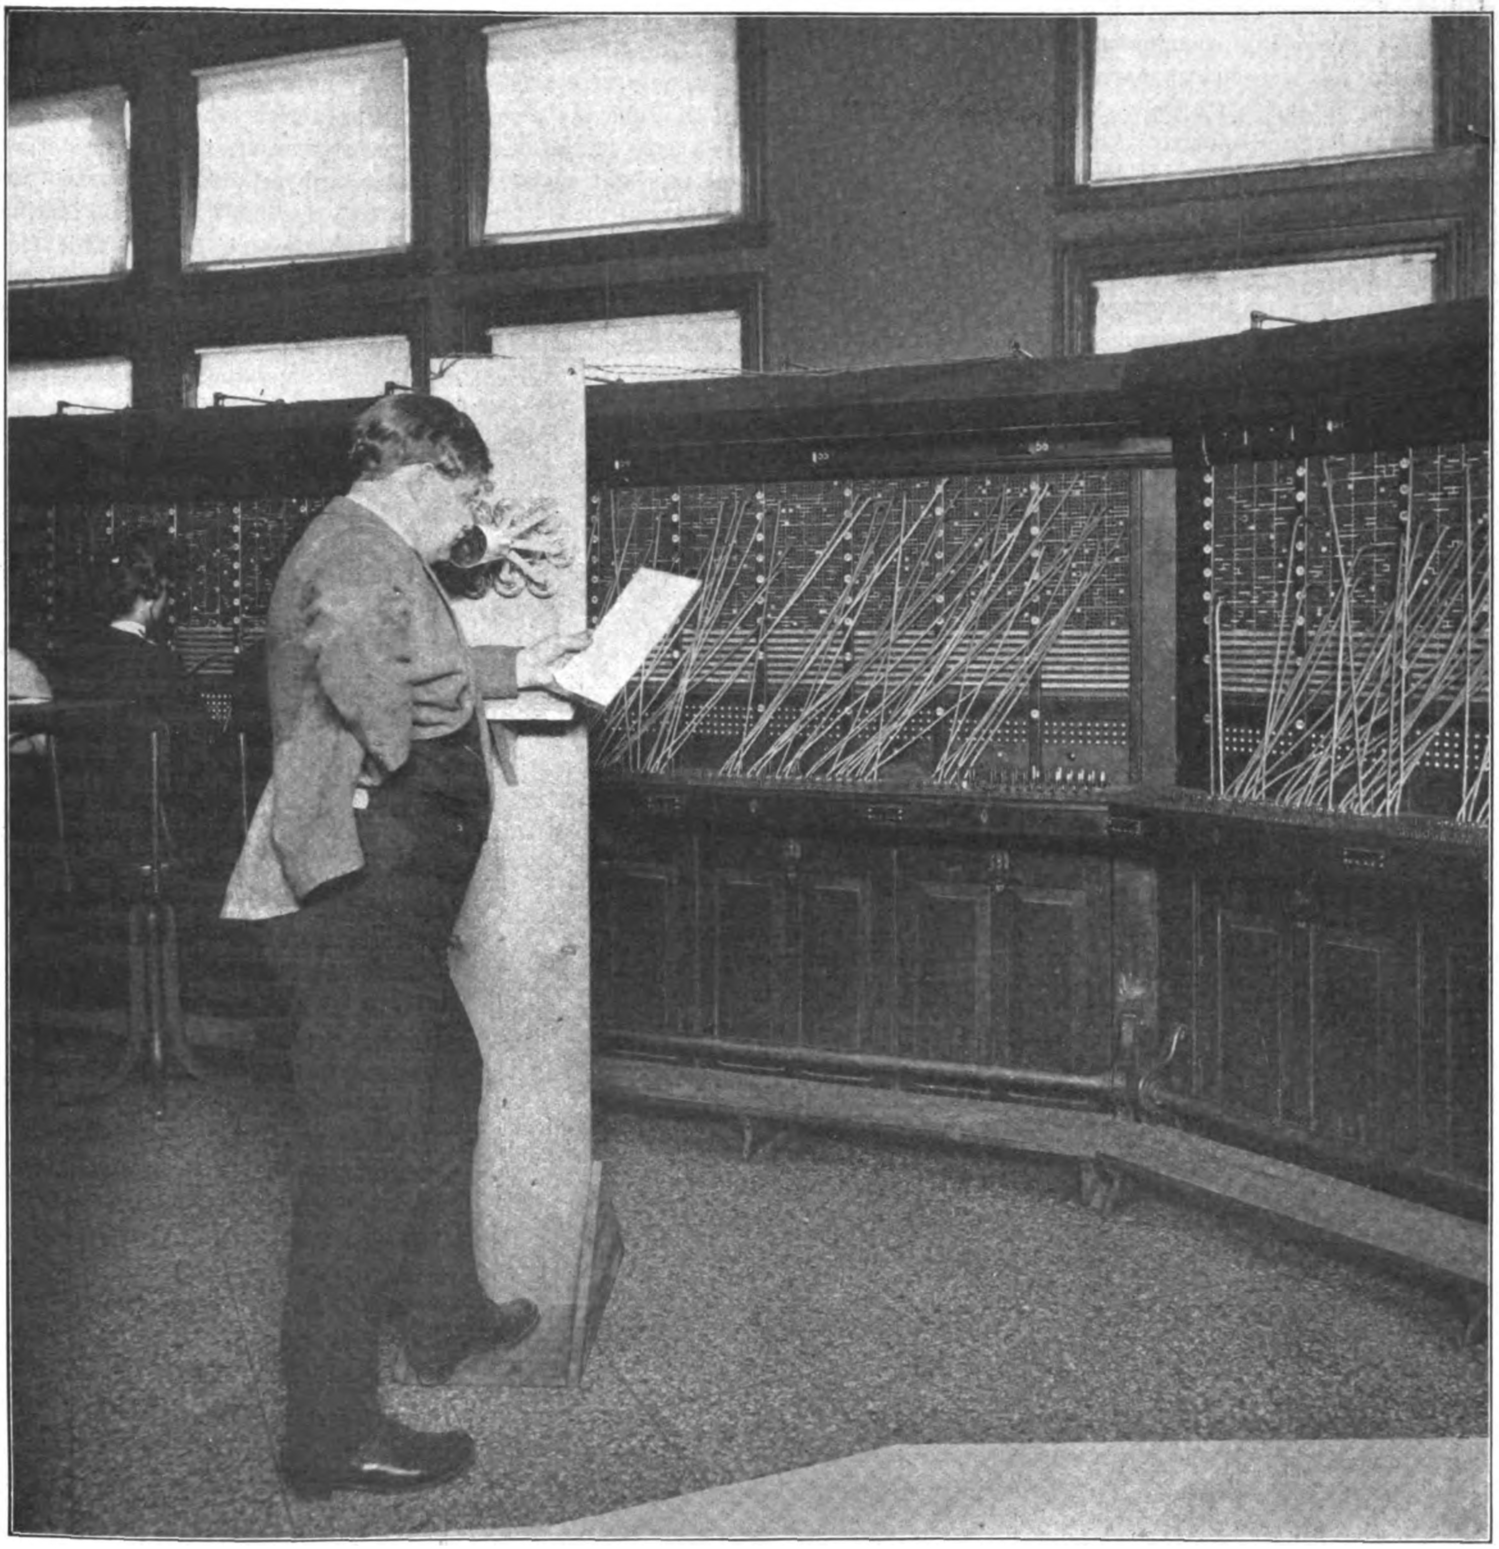
The Chicago Telephone Company has for many years distributed election news to telephone subscribers generally, as well as to newspapers, clubs and public gatherings. This year the demand for the service was greater than ever before, and preparations for the bulletin transmission were necessarily more elaborate. An entire floor of the company's new toll building at 87 Franklin Street was devoted to this work. Here were gathered about 175 men, engaged in receiving, compiling, editing and transmitting election news and bulletins throughout the night, and from about 5 o'clock p. m. until after midnight this was the center of election-news activity in the city. A photograph, reproduced herewith, shows the election-news force at work. Three sets of bulletins were prepared; the continuous bulletins, which averaged one a minute, the ten-minute bulletins for Chicago subscribers, and the thirty-minute bulletins for the suburban area. Special readers transmitted the continuous bulletins to newspapers, clubs and various public gatherings. These readers, by a combination of instruments, shown in the accompanying illustration, were able to talk into ten transmitters at the same time, and in some cases four or five lines were



CHICAGO TELEPHONE COMPANY ELECTION SERVICE—TRANSMITTING RETURNS TO 225,000 TELEPHONES IN CHICAGO AND VICINITY.

grouped on to each transmitter circuit. The ten-minute bulletins were transmitted by readers directly to each of the company's twenty-three principal exchanges and ten or more neighborhood exchanges in Chicago. Subscribers of these exchanges desiring to receive the news had simply to ask the operator for telephone bulletins. The operator then announced the number of the current bulletin, and ordered the subscribers' lines connected with a group being formed at that moment; the bulletin reader meanwhile was announcing the bulletin to a group previously made up. At the end of each bulletin the reader switched from one group to the other and proceeded with his work. At the close of each bulletin the subscribers' lines in the group were disconnected, and they were able to call again for the next bulletin. The total number of calls for election news received in this way during the evening was 53,298. The greatest number came from exchanges in the residence districts, where thousands of subscribers heard the latest election news without leaving their own homes.

Many commendations of the press and subscribers have attested to the remarkable telephone-bulletin service throughout the country on election night, and the success of the bulletin transmission has demonstrated once more that the telephone is one of the greatest and quickest news distributors.



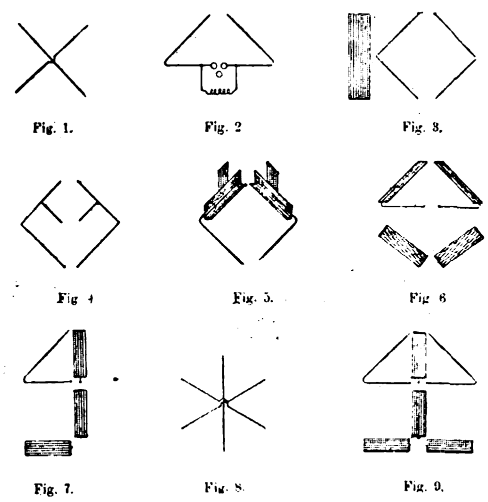
CHICAGO TELEPHONE COMPANY ELECTION SERVICE—READING BULLETINS OF THE ELECTION RETURNS TO MORE THAN 200 TELEPHONES AT THE SAME TIME BY AID OF MULTIPLE TRANSMITTER.

The Artom System of Radiotelegraphy.

Whoever has followed in the slightest the marvelous development of wireless telegraphy must certainly be aware of the serious difficulties that were in the way of the practical application of this wonderful method of communication, says Professor Alessandro Artom in a communication to the Italian Electrotechnical Association, and printed in the "Atti Della Associazione Elettrotecnica Italiana," Vol XII, No. 4, July-August, 1908. It happened continuously that wireless messages sent by a certain transmitting station were caught by all the receiving stations within the circle comprising the average transmitting distance of the station. Atmospheric electricity also caused serious disturbances, so that at times the service had to be suspended for hours. It was necessary to give to the phenomenon of the propagation and reception of the electric waves a much more definite character and, in order to meet the exigencies of practice, it was necessary to develop systems of radiotelegraphy which would make it possible (1) to send the effects of the transmitting apparatus mostly in one definite direction—that is, to find means of directing the electric waves; (2) to render the receiving apparatus most sensitive to waves coming from a certain direction; (3) to prevent the serious disturbances due to atmospheric electricity; (4) to make the receiving apparatus insensitive to waves emanating from extraneous transmitters. Artom says:

"When the work of Marconi was first announced it occurred to me that for a practical solution of the problems mentioned he might have turned to the use of phase difference between two or more electrical oscillations. To produce practically a difference of phase between two Hertzian vibrations of the order employed in wireless telegraphy appeared at that time impossible, but later the idea spread and it is now applied in numerous wireless systems. In my own work I have found it most useful to employ rotating electric and magnetic fields generated by two electrical oscillations differing in phase for proving the existence of phase differences, as will be clearly seen from the experiments here described.

"The rotating magnetic field is generated by two windings, through one of which flows the principal oscillating current, and through the other a current induced by means of a small transformer of a few turns. The existence of the rotating magnetic field can be easily demonstrated by introducing an armature into the field. The existence of very high-frequency rotating electrostatic fields may be demonstrated in various ways, for example, by the use of a Braun tube, which obviously is also eminently suitable for showing the magnetic field. In order to influence the cathode beam of the Braun tube by the vibrations of the high-frequency electric field it is only necessary to fasten to the neck of the tube, a little below the diaphragm, two pairs of tinfoil strips, properly insulated, at right angles to each other on the periphery of the tube, and connect the strips with four points of the oscillating circuit, between which there exist differences of potential out of phase. The effects of a rotating electric field may thus be easily observed; the cathodic spot describes open elliptical forms manifesting themselves in the shape of



SHOWING THE DISPOSITION OF THE CONDUCTING AERIALS USED IN THE ARTOM SYSTEM OF WIRELESS TELEGRAPHY.

spirals, since the oscillations are damped. These elliptical forms, according to which the electric lines of force resulting from the composition of two electrical oscillations of different phase arrange themselves, may conveniently represent a transverse section of a beam of rays of electric force analogous to a beam of light polarized elliptically. Having thus demonstrated experimentally the composition and interference of two electrical vibrations, I endeavored to apply the effect to wireless transmitting and receiving apparatus with a view of producing unsymmetrical electromagnetic fields and devised for this purpose a number of arrangements of aerial conductors which constitute one of the characteristics of my system of radiotelegraphy. They are represented in Figs. 1 to 9, and consist of two or three aerial conductors inclined toward each other at angles which may vary from zero to 180 degrees, but which may generally be most conveniently chosen between forty-five and ninety degrees. When oscillatory currents of displaced phase are sent into aerial conductors arranged in this manner they possess remarkable properties regarding transmission as well as receiving, as experiments made under the auspices of the Italian Royal Navy have shown. As regards the transmitting aerials, the following facts will be observed at once: (1) in the aerials inclined toward each other the mutual induction is very small, when oscillating currents flow through them. This fact permits of establishing absolutely in advance the period of oscillation to be used in the transmission.

"(2) The inclination of the aerials toward each other serves to produce the phenomena of composition and interference between electromagnetic waves emitted by two conductors, because it compels a superposition of the respective beams of electric and magnetic lines of force.

"(3) When connected to an oscillator or to a receiver, these two aerial conductors constitute an arrangement that is in electrical equilibrium, in the sense that the electrical capacities of the two branches, with regard to the earth, are of remarkably equal value, so that the ground connection of the transmitting as well as receiving apparata may be eliminated, as has been demonstrated in practice. This is of practical advantage.

"The various types of aerials shown are approximately equal in their effects, but the triangular arrangement presents some practical advantages in that it requires only one mast. Experience has shown, furthermore, that with this arrangement it is possible to obtain quite well conditions of syntony between transmitter and receiver.

"The characteristic property of the transmitting apparatus is the production of a profoundly unsymmetrical magnetic field, that is, directed electric waves, as the experiments made by the Royal Italian Navy have demonstrated. The use of inclined aerials alone evidently constitutes a reason for the unsymmetrical character of the effects. But an experience of years has demonstrated a property, which is also possessed by some other systems using two aerials, namely, that the axis of propagation according to which the electromagnetic effect reaches the greatest distances, may be perpendicular to the plane of the aerials, or it may lie in the plane of the aerials themselves. When the oscillating currents in the aerials are made to differ in intensity as well as in phase, that is, if they are of different amplitude, this axis of greatest propagation may be inclined in any direction with respect to the plane of the aerials. This fact is useful in practice, as a wireless telegraph station should evidently be able to meet any special conditions imposed by its topographical position.

"In fact, it is possible to vary the constructive elements or form of these aerials as well as their electrical elements, that is, the amplitude and phases of the oscillating currents by which they are excited. Furthermore, supplementary aerials may be added which, if arranged, as shown in Fig. 4, will greatly reduce the radiation in the direction of the plane of the aerials. Their effect is evidently to generate interfering fields, or fields opposite in sign to the principal electromagnetic field. In experiments made in 1904, in which these aerials were lengthened and arranged almost horizontally in the direction of the receiving station, an increase of radiation in that direction was observed.

"As has been stated, the electrical elements of the apparatus may also be varied; it may be operated with or without ground connection, the difference of phase between the currents may be varied from zero to 180 degrees, and the relation of the amplitude between the two currents may be made to differ. Thus it will be seen that with the arrangement described it is possible to obtain curves of distribution of energy corresponding to the most widely differing azimuth angles, these curves being the natural consequence of the arrangement devised by me.

"In order to apply the idea of phase difference to the reception of signals I devised various types of receiving apparatus, but the one that proved most successful was an arrangement resembling the differential galvanometer, and is illustrated in Fig. 10. Three coils are arranged on a core which may be of insulating material or of iron wires. The central coil is connected to any kind of electric wave detector. Alongside of the central coil are two other coils, each of which has one of its terminals connected to one of the two antennæ, the other ends are joined together and may be connected to the ground or not. These two coils may be made to act by induction on the central coil in such a way that their effects are either in opposition or in accord. When they act in accord on the central coil and the apparatus is connected to the ground, it will receive signals like an ordinary aerial from whatever direction they may come. But when the two receiving antennæ are arranged in the plane of the waves arriving from the transmitter, the waves strike first one aerial and, after a certain time, the other one that is farther removed from the transmitter. The magnetic flux generated in the two coils induces currents in the central coil, which is connected to the detector and behaves

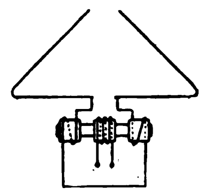


FIG. 10.—ARTOM SYSTEM OF WIRELESS TELEGRAPHY.

according to known laws. Assuming, on the other hand, that the two aerials are affected at the same instant, then the flux generated in the two coils is equal, of the same phase and opposite in direction, and the effect on the induced circuit connected to the detector is practically nil. The result is that from all transmitting stations outside of the plane of the receiving aerials, and more particularly from those stations in a perpendicular direction, the electromagnetic effects arrive at the two receiving aerials at the same instant and the receiving apparatus is not sensitive to them. The same is true in the case of electric waves due to atmospheric electricity. When the ground connection is eliminated the two coils may be dispensed

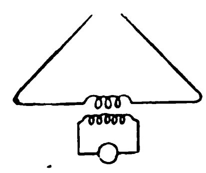

FIG. 11.—ARTOM SYSTEM OF WIRELESS TELEGRAPHY.

with and the apparatus assumes the simple form shown in Fig. 11, and its operation is then principally due to the electromotive force resulting from the magnetic flux traversing the space included by the aerials. The effect is maximum when transmitting and receiving aerials lie in the same plane. This physical fact was made use of by me in the fall of 1905 with very good results for determining the position of transmitting stations on vessels and on land.

"The selective properties of my receiver with triangular aerials have been made still more distinct by the use of electromagnetic syntony, and special apparatus were invented in which, in addition, local syntony was employed, that is, the apparatus has a slow natural period of vibration at which alone it will operate. This local syntony is determined, as regards the transmitter, by the low-frequency current feeding the coils or transformers and, as regards the receiver, by a very weak alternating current under the influence of which only the receiver can act. This apparatus was devised about two years ago, and in experiments made proved to be very sensitive and well suited as a receiver in wireless telephony."

Annual Meeting of the American Society of Mechanical Engineers.

The twenty-ninth annual meeting of the American Society of Mechanical Engineers will be held in the Engineering Societies' Building, New York, on December 1 to 4, inclusive. The opening session will be held on Tuesday evening, when President M. L. Holman will make an address on "The Conservation Idea as Applied to the Associated Societies of Mechanical Engineers," which will be followed by an informal reception and reunion.

On Wednesday morning, following the annual business meeting, a paper on "Aeronautics" will be presented by Major G. O. Squier, U. S. A. The afternoon will be devoted to four papers relating to steam and power plants, among these being one by C. R. Weymouth on "Fuel-economy Tests at a Large Oil-burning Electric Plant." In the evening Lieut. F. P. Lahm, U. S. A., will deliver a lecture on "Aeronautics," illustrated by stereopticon views and moving pictures.

On Thursday morning five papers on machine-shop practice will be presented and discussed. In the afternoon while the main body will consider five miscellaneous papers, the Gas Power Section will take up two papers by Prof. F. C. Wagner and L. H. Nash.

On Thursday evening the annual reception will be held, followed by dancing and a collation.

The professional sessions will be concluded on Friday morning with the consideration of four papers giving various experimental methods and results. Among these will be one on "An Averaging Instrument for Polar Diagrams," by Prof. W. F. Durand.

At the annual meeting last year 1,232 members and guests were present. This number, it is believed, will be greatly exceeded this year.

SOME PRELIMINARY STEPS IN HYDRO-ELECTRIC ENGINEERING.

BY FRANK KOESTER.[1]

In developing waterpowers much preliminary study has to be made to ascertain whether or not the proposition will be a paying one. A lot of facts have to be collected before capitalists can be interested in the project, showing them where and how they can receive the best returns from their investment.

Usually the first steps toward a waterpower development are made by some progressive individual in the neighborhood of an undeveloped waterpower and not by the manufacturer or power user with an already established steam-generating station, who in some respects even tries to handicap the development for fear of the partial loss of the money invested in his old plant. He overlooks the fact, however, that current may be purchased much cheaper from a main central station than his own plant can generate it. Besides this, he is relieved of the work of generating current and has additional ground area for increased manufacturing purposes.

Another reason why a promoter can best, and possibly with greater success, further the scheme of development is because he has the interest of the community at large under consideration, while the individual manufacturer looks after his own interests alone. Again, the endeavor of the promoter is to utilize as much energy as possible, while the manufacturer utilizes only a portion, which is sufficient for his own needs.

In some localities, particularly when he comes from the "outside," the promoter is looked upon as a persona non grata, while in reality he is a benefactor. Through his efforts and the supplying of current the industry will be improved and in some cases new industries previously unknown will arise. This is not only a direct benefit to the community, but even the towns and counties will be benefited by the increase in revenues, taxes, etc.

After the investigations are made, showing the amount of the energy that can be utilized, the possible field of consumption must be carefully mapped out. This field may include other central stations, either steam, gas or other waterpower plants, with which the new station has to compete. While it is known for what price the established plants sell their current, it might appear on the surface difficult to ascertain what the existing companies pay for the generation of the same. There are, however, several ways by which this information may be obtained, and with the help of an experienced investigator who is thoroughly familiar with plant installations, very close figures can be ascertained.

These figures are very essential as a guide for the new development, because the new arrival has to compete with or possibly sell current to established stations at a lower price than they can generate it. This might lead to the operation of the stations in parallel, or eventually the incorporation of the old with the new concern and the gradual acquisition of the competitor's field. All this can only be accomplished by deciding the question, who can generate power the cheapest?

Having arrived at the competitor's figures, the prospective field for current consumption must be thoroughly canvassed to ascertain the load on the plant and the price for which the current of the new undertaking can be sold. In analyzing the cost of the current to be sold, of course, different prices are charged, according to the amount, duration and time of load. Conclusions as to the cost of current can only be derived after trial load curves of the proposed plant have been plotted.

Such plants will be most economic in operation which have a practically constant load-factor, as otherwise much machinery has to remain idle during the twenty-four hours. However, in competing successfully with existing central stations or private plants the new arrival cannot afford to overlook would be consumers who require current for only a few hours each day, or possibly the week, and those which need emergency current in case their own plant should fail. That these consumers pay accordingly for the service rendered is but natural. It must, however, be borne in mind that the lower the price for current delivered the greater is the tendency to improve the load curve of the plant.

After the foregoing investigations have been made and the figures warrant an installation, the possible future growth of the locality, such as the increase in industrial districts, electric railroading, etc., must be well considered, since an increase of the community is naturally followed by an increase in consumers.

Many times hydro-electric plants have been installed with no provision for future extension; the dams are located in such sections of the rivers and are of such a design that an increase in storage supply or additional head is impossible. On the other hand, and to a still greater extent, plants have been installed at such sections of rivers or localities that the average water supply cannot be obtained during certain seasons of the year. While the former may be due to the failure to exercise sufficient foresight, the latter may be considered as negligence in proper investigation as to the watershed, etc. Under such conditions successful competition with existing plants would be a difficult proposition in the long run.

Waterpower plants do not in many cases have to meet with competition, as they may be the pioneers in the field. If other conditions are favorable to the development of a certain waterpower the hydraulic plant may be combined with a steam or gas-driven plant to take care of low water conditions and peak loads.

The equipment of the plant and the size of the units should be such that they can be run to their best efficiency throughout the day, that is, they must not be underloaded or overloaded too much. Reserve units must be kept in readiness to be thrown on the line when the demand calls for them. The tendency is to install as large individual units as possible.

In closing it may be said as a general rule that promoters and financiers look usually for large waterpower developments, while as a matter of fact small plants give a better and quicker return for the money invested.

[1] Consulting engineer, New York city.

Court Reserves Decision in New York City's Application to Examine Edison and United Electric Books.

Justice McCall, in the New York Supreme Court, reserved decision on the application of the city of New York for an order authorizing it to examine the books and plants of the New York Edison Company and the United Electric Light and Power Company.

The corporation counsel said that he desired the examination for the purpose of defending the suits brought by the two companies to recover about $500,000 for furnishing electricity to the city for the year 1903.

Counsel for the electric light companies said that all the information that could be obtained by such an examination was contained in the public records of the report of the Stevens investigating committee of 1905, and asked the court to deny the application.

FINANCIAL REPORTS OF ELECTRICAL COMPANIES.

CHICAGO RAILWAYS.

The Chicago Railways Company reports earnings for the month of August and seven months (February 1 to August 31) as follows: August—Passenger earnings, $959,167; other income, $20,999; total gross, $980,166; expenses, $650,128; balance, $330,038; balance, 30 per cent of gross, $294,049; interest on property, five per cent, $144,250; net earnings, $149,799; city's share, 55 per cent, $82,389; company's share, 45 per cent, $67,409, as against $95,621 for August, 1907. February 1 to August 31—Passenger earnings, $6,128,269; other income, $132,514; total gross, $6,260,783; expenses, $4,287,024; balance, $1,973,759; balance, 30 per cent of gross, $1,878,233; interest on property, $971,230; net earnings, $907,003; city's share, 55 per cent, $498,851; company's share, 45 per cent, $408,152, which compares with $442,503 for the corresponding period of 1907.

SEATTLE LIGHTING COMPANY BONDS.

The Seattle Lighting Company recently sold $450,000 ten-year, six per cent debenture gold bonds, redeemable on any interest day, at 101. This is added to an authorized issue of $3,000,000 of five per cent bonds, which makes the authorized bonded debt of the company $3,450,000. The financial statement showing funded debt charges is as follows for the year ended July 31, 1908: Gross earnings $560,325; net (after insurance and taxes), $252,695; interest on mortgage bonds, $124,073; interest on debentures, $27,000; balance, surplus, $101,622. Net earnings for the year ended June 30, 1908, were $252,287 and for 1907, $218,972.

There is an equity in the property over and above all the first mortgage bonds outstanding of approximately $1,500,000, which equity stands as security for this issue of $450,000 debenture bonds.

PHILADELPHIA COMPANY.

The report of the Philadelphia Company and affiliated corporations shows earnings from all operations for the nine months ended September 30, 1908, as follows: January 1 to September 30: Gross, $12,261,314; expenses and taxes, $7,453,833; net, $4,807,481; other income, $193,834; total income, $5,001,315; charges, rent, etc., $3,351,513; balance, $1,649,802; preferred dividend, $225,000; surplus, $1,424,802, compared with $1,969,602 for the same months in 1907.

BOSTON ELEVATED.

The annual report of the Boston Elevated Railway Company for the year ended September 30, 1908, shows as follows: Gross, $14,074,696; expenses, $9,454,386; net, $4,620,310; total increase, $4,620,310; charges, $2,780,246; surplus, $840,064; dividends, $798,000; surplus, $42,064, which compares with $33,278 for 1907. The balance sheet as of September 30, 1908, shows assets of $35,128,644 and a surplus of $2,717,980, which includes $2,036,900 premiums received from the sale of securities in 1907 and $2,007,314 in 1908. The number of revenue miles was 51,625,143 and the passengers carried 273,132,584.

KANSAS CITY RAILWAY AND LIGHT.

The report of the Kansas City Railway and Light Company for the month of September and four months ended September 30, 1908, is as follows: September gross, $537,301; expenses, $289,330; September net, $247,971; charges and taxes, $155,181; September surplus, $92,790, as against $115,786 for September, 1907. Four months' gross, $2,113,843; expenses, $1,212,137; four months' net, $901,706; charges and taxes, $620,530; four months' surplus, $281,176, comparing with $394,937 for the corresponding period of 1907.

ELECTRICAL SECURITIES CORPORATION.

The Electrical Securities Corporation, which is the holder of mortgage bonds of certain electric railway, light and power companies, has issued its report for the year ended October 31, 1908. The profit and loss account shows as follows: Bond interest received and accrued, $292,279; dividends on stocks, $56,735; total, $349,014; collateral trust bond interest, $137,712; interest general account, $17,672; expenses, $52,811; total expenses, $208,195; net profit, $140,819; profits from sale of securities, $4,101; total net profit, $144,920; previous surplus, $868,885; total surplus, $1,013,805, decrease in value of assets, $402,594; baalnce, $611,211; preferred dividend, $50,000; profit and loss surplus, $561,211, as against $868,886 for the year 1907. The statement of assets and liabilities as of November 1, 1908, shows total assets of $8,166,893, compared with $7,443,826 for the previous year.

INTERNATIONAL RAILWAY COMPANY.

The International Railway Company of Buffalo, N. Y., report as filed at Albany for the quarter ended September 30, 1908, is as follows: Gross, $1,349,900; expenses and taxation, $798,102; net, $551,798; other increases, $6,052; total increases, $557,850; charges, $224,768; surplus, $333,082, as compared with $415,389 for the corresponding quarter of 1907. The assets are given as follows: Cost of road, $31,536,025; interest and dividends receivable, $7,291; material and supplies, $386,053; cash assets, $436,293; accounts receivable, $608,271; International Traction Company car trust license account, $1,349,389; funded debt of other corporations, $360,000; stock of other corporations, $61,200; special deposits, $106,852; prepayments, $62,526; grand total, $34,913,903. Liabilities—Funded debt, $10,858,000; current liabilities matured and unpaid, $164,739; current liabilities unmatured, $534,272; loans, International Traction Company, $4,672,593; reserve for replacement and renewals, $91,322; other reserves, damages, $190,136; stocks, International Traction Company car account, $697,249; real estate mortgages, $38,850; common stock, $16,320,500; corporate surplus, $1,346,239; grand total, $34,913,903.

The Crosstown Street Railway of Buffalo, which is controlled by the International Railway Company of Buffalo, reports for the quarter ended September 30 as follows: Gross, $167,933; expenses and taxation, $101,759; net, $66,174; charges, $37,175; surplus, $28,995, as against $38,088 for the same quarter of 1907.

FONDA, JOHNSTOWN AND GLOVERSVILLE.

Fonda, Johnstown and Gloversville's report, as filed at Albany, N. Y., for the quarter ended September 30, 1908, shows as follows: Gross operating revenue, $224,720; operating expenses, $100,205; net operating revenue, $124,515; other net revenues, $2,244; total net revenue, $126,759; taxes accrued, $8,250; operating income, $118,509; other income, $4,862; gross income, $123,371; charges, $85,907; net income, $37,464, as against $53,615 for the corresponding period of 1907. The cash on hand September 30, 1908, was $32,581; profit and loss surplus, $479,769.

AMERICAN TELEPHONE.

The net earnings of the American Telephone and Telegraph Company for October and ten months ended October 31, 1908, are as follows:

Month of October: Dividends, $2,516,541; interest and other revenues, $789,-

921; telephone traffic net, $491,887; real estate, $15,382: other sources, $81,-493; total earnings, $3,895,223; expenses, $164,305; net, $3,730,918; interest, $666,-100; balance for dividends, $3,064,809, which compares with $2,568,707 for October, 1907. January 1 to October 31—Dividends, $12,550,557; interest and other credits, $8,087,075; telephone traffic, net, $3,473,494; real estate, $135,516; other sources, $647,908; total earnings, $24,-894,552; expenses, $1,736,060; net, $23,-158,492; interest, $6,380,746; balance for dividends, $16,777,746; dividends, $9,-289,624; surplus, $7,488,122, against $5,822,790 for the same months of 1907.

NORTHERN OHIO TRACTION.

The report of the Northern Ohio Traction and Light Company for the month of October and ten months ended October 31 is as follows: October gross, $157,532; expenses, $90,238; October net, $67,274; charges, $43,779; October surplus, $23,-495, an increase of $9,274 over the corresponding figure for 1907. Ten months' gross, $1,579,081; expenses, $913,301; ten months' net, $665,780; charges, $435,-783; ten months' surplus, $229,997, as compared with $263,257 for the preceding year.

SUSQUEHANNA RAILWAY LIGHT AND POWER.

The Susquehanna Railway, Light and Power Company's report for the year ended June 30, 1908, shows as follows: Receipts from subsidiary companies, interest on bonds owned, etc., $551,479; interest on bonds and dividends on stocks of subsidiary companies, $244,980; balance available for dividends, $306,499; dividends, 131,632; undivided surplus, $174,867. The surplus available for dividends is equal to five per cent on the preferred stock and 2.5 per cent on the common stock.

During the year a sum in excess of one million dollars was authorized and expended for extensions, additions and betterments to the various properties, which expenditures were authorized to meet absolute requirements made necessary by increased business.

UNITED RAILWAYS OF ST. LOUIS.

The report of the United Railways of St. Louis for the month of October and ten months ended October 31 shows as follows: October gross, $949,914; expenses, $572,325; October net, $377,589; charges, $233,846; October surplus, $143,-743; ten months' gross, $8,810,538; expenses, $5,645,405; ten months' net, $3,165,133; charges, $2,321,176; ten months' surplus, $843,957, a decrease of $22,013 over the preceding year.

GALVESTON-HOUSTON ELECTRIC.

The report of the Galveston-Houston Electric Company for the month of September and twelve months ended September 30, 1908, is as follows: September gross, $91,790; expenses, $46,620; September net, $45,170; charges and taxes, $17,450; balance, $27,720; sinking fund, $2,670; September surplus, $25,-050, a decrease of $164 over September, 1907; twelve months' gross, $1,060,002; expenses, $620,378; twelve months' net, $439,624; charges and taxes, $209,812; balance, $229,812; sinking fund, $31,-427; twelve months' surplus, $198,385, a decrease of $6,393 as compared with the preceding year.

SEATTLE ELECTRIC.

The report of the Seattle Electric Company for the month of September and twelve months ended September 30 shows as follows: September gross, $385,946; expenses, $209,952; September net, $175,994; charges and taxes, $86,-001; balance, $89,993; sinking fund, $7,344; September surplus, $82,649, an increase of $15,839 over September, 1907. Twelve months' gross, $4,425,520; expenses, $2,670,185; twelve months' net, $1,818,335; charges and taxes, $965,519; balance, $852,816; sinking fund, $88,-579; twelve months' surplus, $764,237, a decrease of $20,641 as compared with the corresponding period of 1907.

DALLAS ELECTRIC.

The report of the Dallas Electric Corporation and subsidiary companies for the month of September and twelve months ended September 30 shows as follows: September gross, $95,842; expenses, $63,080; September net, $32,-762; charges and taxes, $24,623; balance, $8,139; sinking fund, $3,333; September surplus, $4,806; twelve months' gross, $1,148,061; expenses, $772,430; twelve months' net, $375,631; charges and taxes, $313,411; balance, $62,220; sinking fund, $40,000; twelve months' surplus, $22,220, a decrease of $3,376 as compared with the surplus for the previous year.

MINNEAPOLIS GENERAL ELECTRIC.

The report of the Minneapolis General Electric Company for the month of September and twelve months ended September 30 shows as follows: September gross, $81,898; expenses, $34,413; September net, $47,485; charges and taxes, $32,310; September surplus, $15,175; twelve months' gross, $973,993; expenses, $432,362; twelve months' net, $541,631; charges and taxes, $365,542; twelve months' surplus, $176,089, a decrease of $29,190, as compared with the figure for the preceding year.

INTERBOROUGH RAPID TRANSIT.

Interborough Rapid Transit report, as filed with the Public Service Commission, for the quarter ended September 30, 1908, shows as follows: July 1 to September 30—gross, $5,328,887; expenses, $2,675,709; net, $2,653,178; other income, $337,175; total income, $2,990,352; interest on funded debt, $500,000; property taxes, $87,627; special franchise taxes, $310,000; balance, $2,092,726; rentals, $1,998,429; discounts and expenses, $3,108; surplus, $91,189, a decrease of $115,902 over the corresponding quarter of 1907. The income accounts of the two divisions of the Interborough Rapid Transit Company, showing the amount contributed by each toward the quarter's earnings, follow: Main division—gross, $3,093,838; expenses, $1,-587,198; net, $1,506,640; other income, $129,330; total income, $1,635,970; property taxes, $72,627; special franchise taxes, $310,000; balance, $1,253,343; rentals, $1,462,656; deficit, $209,313. Subway division—gross, $2,235,049; expenses, $1,088,511; net, $1,146,538; other income, $207,845; total income, $1,354,-383; interest on funded debt, $500,000; property taxes, $15,000, balance, $839,-383; rentals, $535,773; discount and expense, $3,108; surplus, $300,502.

Purdue Students' Inspection Trip.

About seventy students, members of the senior class in the electrical department of Purdue University, were the guests of the Fort Wayne Electric Works Company on November 11. During the day after inspecting the Fort Wayne plant the party visited the plants of the Hoffman Street Lamp Company and the power plant of the Fort Wayne & Wabash Valley Traction Company. Prof. C. F. Harding, Prof. H. T. Plumb and W. T. Small, of the Purdue electrical faculty, accompanied the students.

ALTERNATING CURRENTS AND THEIR APPLICATIONS.

BY EDSON R. WOLCOTT.

CHAPTER I. (PART IX.)—POLYPHASE CURRENTS.

CURRENT AND VOLTAGE RELATIONS IN THE Y SYSTEM.

The relation between the electromotive force generated in one coil of a Y or star-connected, three-wire, three-phase system and the potential difference between the two transmission wires connected to their terminals is determined as shown in Fig. 28. AO, OB and OC represent the three electromotive forces generated in each of the coils A, B and C of Fig. 25. They are 120 degrees out of phase with each other, just as the currents are. The potential difference between any two transmission lines is the resultant of the electromotive forces generated in the two coils connecting them, as represented in Fig. 25, printed last week. There, A, B and C represent the coils, and the potential difference between mains 1 and 3 is equal to the resultant of the electromotive forces generated in coils A and B. It is, in fact, equal to the difference between the electromotive force generated in A and that generated in B when the difference in phase between the two is taken into consideration.

Let OA in Fig. 28 equal the electromotive force generated in coil A and OB that generated in coil B. The sum of the two is equal and opposite to OC, but OB — OA is the resultant of OB and OF, since OF = — OA. If the positive sign represents action in one direction the negative represents action in the opposite direction. The resultant, therefore, of OB and — OA equals that of OB and OF, or OD. It can be shown mathematically that $DO = \sqrt{3}\ OB$.

If OB = E the electromotive force generated in each coil, and E′ that between two mains, or DO, then

$$E' = E\sqrt{3}.$$

The current flowing in the mains is the same as that flowing in the coils.

CURRENT AND VOLTAGE RELATIONS IN Δ SYSTEM.

If the lines AO, OB and OC of Fig. 28 be used to represent a current of strength I flowing in each of the coils of a three-phase, three-wire delta-connected system, then in a similar manner the current in the mains will be found to be $I\sqrt{3}$. The electromotive force between the mains is the same as that across the coils.

RECEIVING CIRCUITS FOR POLYPHASE CURRENTS.

Unless otherwise stated, it is always assumed that the load on a polyphase system is balanced; that is, equal amounts of power are drawn from each circuit. The method of connecting receiving circuits for accomplishing this is practically a reverse method of that of the generating connections. In a two-phase, four-wire system containing motors at the receiving end the windings of the latter would correspond to those of the generator, each of the two phases taking its share of the load.

In a three-phase system the motors would have three separate windings and each phase would take its share of the load.

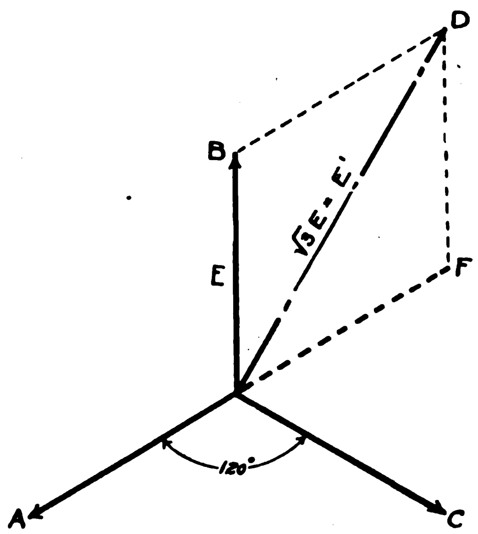

FIG. 28.—DETERMINATION OF ELECTROMOTIVE FORCE IN ONE PHASE OF Y-CONNECTED THREE-PHASE SYSTEM.

When electric lights are connected in a polyphase system they are so arranged that each phase carries the same number, thus maintaining the balance. For example, if twelve lamps are to be connected to a three-phase system, such as was illustrated in Fig. 25, four would be connected between mains 1 and 2, four between mains 2 and 3 and four between mains 3 and 1.

POWER IN POLYPHASE SYSTEMS.

The current flowing through each receiving circuit of a three-phase, Y-connected system is the same as that in the main, but the voltage is $\frac{1}{\sqrt{3}}$ of that between the mains. Representing the latter by E and the former by I, the energy delivered to one phase of the receiving circuit is $\frac{IE}{\sqrt{3}}$, and that delivered to all three phases is $\frac{3IE}{\sqrt{3}}$, or $\sqrt{3}\ IE$.

In the Δ system of connection, let the voltage between the mains, which is the same as that over the coils, be represented by E. The current flowing in the coils is $\frac{1}{\sqrt{3}}$ of that in the main, and the energy delivered to each phase of the receiving circuit is therefore the same as in the Y-connection, that is, $\frac{IE}{\sqrt{3}}$, giving a total of $IE\sqrt{3}$ for all three phases, as before. These calculations are made with the assumption that the load is not reactive, the power being factor unity. If this is not the case, then the total energy delivered is represented by

$$W = IE\sqrt{3}\cos\phi,$$

where $\cos\phi$ is the power-factor.

ECONOMY OF POLYPHASE TRANSMISSION.

Not only is there an advantage in the operation of motors from polyphase circuits as compared to the use of single-phase transmission lines, but there is also a saving in the copper necessary to transmit a given quantity of energy, as is shown by the following calculation:

The current in one coil of a delta winding of a three-phase generator is equal $\frac{1}{\sqrt{3}}$ of that of the current I in the line, as already stated. The energy absorbed in one coil equals $\frac{IE}{\sqrt{3}}$, where E equals the voltage between two lines, and the energy absorbed in all three coils equals $IE\sqrt{3}$. With the Y-connection the power delivered is the same as already stated. Let the resistance of one line be r, with a current I flowing, the loss in transmission in all three lines is $3I^2r$. Consider a single-phase system transmitting the same power and let x equal the resistance of one line; 2x is then the total resistance. The voltage being E, the current will be $\sqrt{3}\ I$, and the loss will be $6I^2x$. If the losses are the same in the single-phase and three-phase systems

$$6I^2x = 3I^2r,$$

or

$$x = \tfrac{1}{2}r;$$

that is, the resistance of one of the two wires of the single-phase system will have one-half the resistance of one of the wires of the three-phase system. It appears, then, that the total weight of copper required to transmit the same energy on a three-phase system is three-quarters of that required on a single-phase system.

[To be continued.]

Association of Car-Lighting Engineers.

Wednesday and Thursday Sessions. Election of Officers. Trip to Milwaukee.

Although its first convention, the meeting of the Association of Car-Lighting Engineers held in Chicago during the five days ending Friday, November 20, demonstrated by attendance and interest the important and useful part the association is to take in the railroad and electrical fields as the art of electric train-lighting progresses. The sessions of the convention were held in the German Room of the Grand Pacific Hotel, and a number of manufacturers occupied adjacent parlors with exhibits of a character interesting to the car-lighting engineers. The banquet in the hotel dining room on Wednesday evening proved the high-water mark in point of attendance, about 200 members, associates and guests being present.

Among the papers read and reports submitted during the first two days of the convention, as reported in full in the ELECTRICAL REVIEW AND WESTERN ELECTRICIAN of last week, were the following:

Monday morning—"The History of Car Lighting," by Patrick Kennedy. "The History of Axle Lighting," by W. L. Bliss. Monday afternoon—Report of the committee on "The Care and Maintenance of Storage Batteries," by F. R. Frost, chairman. "Railway Train Lighting," written by the late A. H. Bauer in 1892. Tuesday morning—Report of the committee on "Straight Electric Lighting," by C. W. Bender, chairman. Report of the committee on "Organization and Systemization in Connection with Electrically Lighted Trains," by E. W. Jensen, chairman.

On Wednesday the association listened to the report of the committee composed of C. R. Gilman, Fred McGary and W. L. Bliss, on the subject of "Head-End Lighting of Passenger Trains."

A head-end system of electric train lighting, the paper defined as a system in which current for all the lamps in the train is derived from a comparatively large dynamo at the head end of the train. This may be, first, a steam-driven dynamo situated on the locomotive; second, a dynamo situated in the baggage car, operated by a belt from the car-truck axle; third, a steam-driven dynamo situated in the baggage car. The same general details go with each of these systems and each requires the storage battery as an auxiliary.

Taking up these systems in detail, there are:

First—Dynamo on locomotive, driven by steam turbine. There are at least two systems of this type on the market, worked out in detail and ready to demonstrate their efficiency as a means to electric-light trains. They are more or less automatic in their operation and aim to reduce the personal equation in the handling to a minimum.

Second—Large axle-driven dynamo situated in baggage car. This system is being worked out by one railroad, and its designer believes in it thoroughly. He is using a double-belt drive. Another arrangement of driving the dynamo has been worked out by a well-known car-lighting company. These systems are reducing the automatic features to a minimum, and this committee is inclined to agree with them, as past history, if observed, is not impressive as to the value of automatic devices operating in railroad service.

Third—Turbine-driven dynamo in baggage car. This system is more generally understood and is in use on quite a number of prominent railroads with fairly good results. In most cases it is being used in connection with gas or oil as an auxiliary light and has proven very economical.

A valuable feature of this report was an itemized statement of the expense incurred by a certain large railroad, operating 900 cars over 7,500 miles of track, in changing over to the head-end system of electric lighting, using turbines deriving steam from the locomotive boiler, and several large batteries in each train. The investment was summed up to be $577,139 for equipping 121 baggage cars with turbine sets and installing wiring and storage cells in other cars. This investment, while very large, the committee thought to be a fair estimate, and believed that no other system could be employed for the same amount. It has been in use for a number of years and has proven its reliability. A table submitted, showing the failures of this system on the Chicago, Milwaukee & St. Paul Railroad, operating 183 electrically-lighted cars in nineteen trains, indicated an average duration without light of only forty-one and one-half seconds per car per day.

The committee on lamps, composed of J. J. Hack, J. M. Schilling, A. J. Farrelly and Ward Barnum, had been instructed to gather information and data regarding the present lamp practice in car lighting and the latest development of incandescent lamps for this service, and to prepare a report on the comparative merits of carbon, tantalum and tungsten lamps. It was found that in the past the car-lighting lamp business was not sufficient to warrant any particular manufacturer to give the necessary attention for its development, especially inasmuch as there are now over twelve different voltages in use on the various roads, ranging from fifteen to 110 volts, and also a like variation in candlepowers.

The report submitted a number of tables showing volts, candlepower, filament, shape of bulb and useful life of a number of carbon, tantalum and tungsten lamps available for train lighting.

Tungsten lamps of low candlepowers cannot be made at present for the sixty-volt system, for the reason that the filament would be too delicate to stand the vibration of the car. However, tests on these lamps have been very satisfactory, and indications are that they may be used similarly to the carbon lamps for train lighting. Sufficient data have been obtained to show that should any fault develop it can be entirely overcome.

It was found impossible to place the tungsten support in the small G-12 bulb used in berth lighting, and to draw the neck small enough to be fitted with a candelabra base. Furthermore, lamps could not be made tipless. The snap lock of the berth receptacle is another feature that must be taken into account in considering the possibility of using tungsten as a high-efficiency berth lamp, on account of jar.

The committee of the lamp manufacturers appointed to investigate thoroughly the requirements of train-lighting lamps at about the same time the association's lamp committee was named, tendered the suggestion that it would be possible to change the voltage of the different systems now in use so as to reduce them to one or two standards, say, a range from twenty-five to thirty-two volts normal for the low-voltage standard and a range from fifty-five to sixty-two volts normal for a high-voltage standard. The next question arising would be the standard unit to be used in car lighting. Another matter is that of abolishing all special lamps excepting the berth lamp and perhaps two other types, these lamps to be used in all cases where special lamps are now used.

The lamp committee's report concluded with a number of curves furnished by the engineering department of the National Electric Lamp Association, showing comparative performances of carbon, tantalum and tungsten lamps. One of these was especially interesting and showed the saving of one twenty-four-candlepower tungsten over carbon and tantalum of equivalent candlepowers for various costs of power per kilowatt-hour.

Mr. H. C. Meloy's paper on "Illumination," tendered as the report of the committee of which he is chairman, contained the results of a number of tests of the illumination of car interiors with various kinds and arrangements of lights. The author advised the use of lighter colors for finishing the interiors of railroad cars.

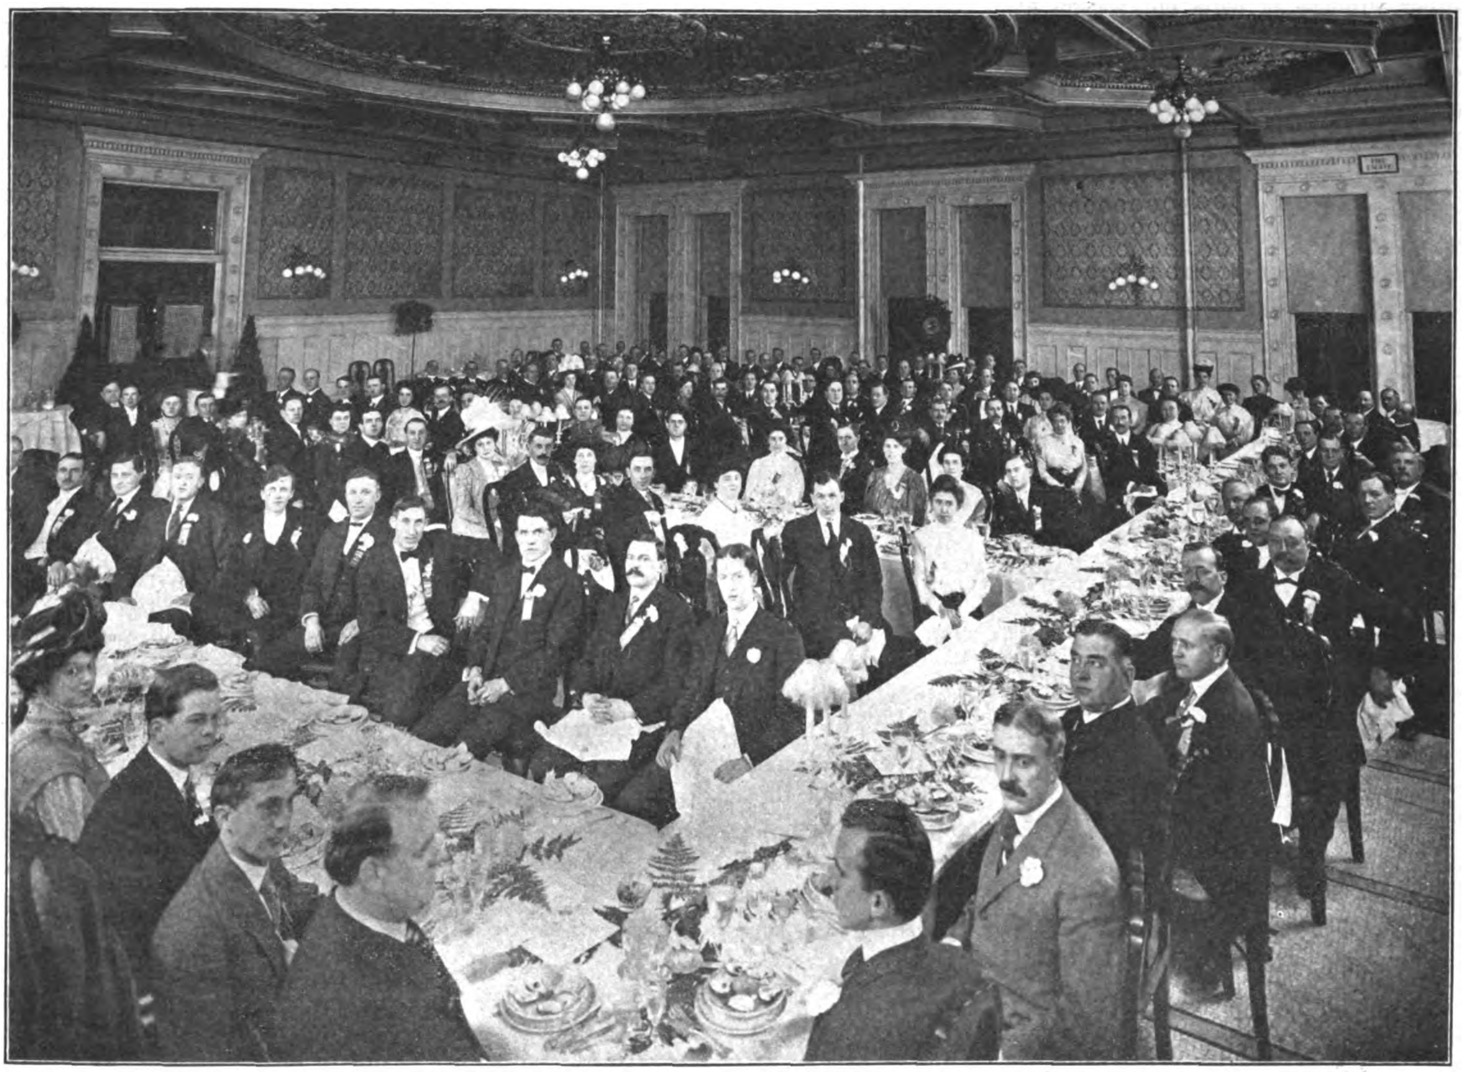
In response to the inquiries of a number of the members, W. E. Ballentine of the Rock Island Railroad recounted the experience of his company with Cooper Hewitt mercury-vapor lamps for lighting mail cars. At a cost of $5.35 per car-month for maintenance, these lamps, he said, gave an illumination 570 per cent greater than that obtained with gas. The average life of a tube in this service is 9,000 hours. The lighting system is carried out with fifty-five volts, and on account of the marginal property of the mercury-vapor tube, which prevents its operation unless a certain potential is impressed across the terminals, there is no danger of running down the storage cells to exhaustion or sulphation.

On Wednesday evening the annual banquet of the association was held in the great dining room of the Grand Pacific Hotel. Almost two hundred members, associates and guests attended and enjoyed the excellent and well-appointed service. Following the gustatory courses the banqueters listened to a number of toasts, with Godfrey H. Atkin, of the Electric Storage Battery Company, presiding at the speakers' table. Toasts were given as follows:

"Our Association," President A. J. Farrelly, Electrical Engineer, Chicago & Northwestern Railway; "Car Lighting from an Operating Standpoint," George H. Groce, Superintendent of Telegraphs, Illinois Central Railroad; "Small Beginnings," R. Quayle, Superintendent Motive Power, Chicago & Northwestern Railway; "Buyer and Seller," Colonel J. T. Dickinson, Bliss Electric Car Lighting Company.

The formal programme was interrupted by G. W. Murray, of the Southern Pacific, who, on behalf of the association, presented President Farrelly and Secretary Colegrove with handsome watch-fobs in recognition of their services to the organization.

On Thursday morning two papers remained for discussion by the convention and the executive session that had been planned was postponed until the after-



BANQUET OF ASSOCIATION OF CAR-LIGHTING ENGINEERS, GRAND PACIFIC HOTEL, CHICAGO, WEDNESDAY EVENING, NOVEMBER 18.

noon. The report of the committee on "Practicability of Electric Lighting of Steam-Railway Cars by Straight Storage Systems of Lighting," was presented by W. E. Ballentine, chairman of the committee of which C. J. Causland and R. C. Shaal were the other members.

The efficiency of the straight-storage system, say the committee, is higher than that of any of the other systems. The energy is generated with large, efficient units and is transferred to the lamps in the most efficient manner. There is neither slippage of belts nor wasted energy, as the greatest part of all the energy produced is utilized for the purpose intended. The battery is not overcharged when not necessary. In this connection we must also consider the fact that the straight-storage equipment is considerably lighter than the other equipments and does not utilize as much energy on the road. In the head-end system the energy is taken direct from the locomotive boilers to the generator, and in the axle system the energy is transmitted from the boiler to the engine, to the train, and through the belt to the axle machine.

The cost of maintenance depends largely on the simplicity and efficiency of the system. In the straight-storage system the power plant is stationary and at all times under supervision, which, naturally, will tend to make the maintenance low. The life of the power plant is much longer and the maintenance is much lower than in the other two systems where the power plant is applied to the train and carried back and forth, therefore being subject to considerable strain on account of the jarring. In the straight-storage system the battery is used to its best advantage and is subject to less abuse than with other systems. It will therefore give considerably longer life in this kind of service and will run with less attention. The battery does not receive constant overcharging and overdischarging, causing blowing out of the active material, sulphating, and buckling of plates. The battery is brought up on every charge to the normal point, and, as a rule, is not exhausted on discharge, which very frequently will happen in the other methods. The straight-storage method will work the battery in a regular routine, which naturally gives the most efficient results, and will seldom go to extremes in charging and discharging.

The principal advantage in operating a straight-storage system is the necessity of assigning cars to regular runs and of allowing a sufficient layover for the same between runs in order that the batteries may be properly charged. Ordinarily it takes from six to eight hours to charge the batteries, the time depending on the length of the previous run and also on the charging current available. The next objection to straight storage would be the time-factor, that is, the battery will give only a certain number of car-lighting hours, which makes it impossible to use this system on long through runs. Another serious objection is the impossibility of keeping a constant lamp voltage, which has tendency to greatly shorten the life of the lamps.

The straight-storage system of lighting, the committee concludes, is only practicable where the total car-lighting load, expressed in ampere-hours, does not exceed at the most seventy-five per cent of the rated capacity of the battery. In other words, this means that a factor of safety of at least twenty-five per cent must be allowed to take care of any contingency which might arise from some unknown cause.

A complete analysis of modern axle-driven generating systems was presented by Chester Terry, chairman of the committee on "Axle-Lighting." He described several well-known systems of axle lighting, giving a brief description of the methods of regulation and the distinctive features of the various devices as follows:

"The United States equipment has a shunt-wound generator with one and one-half kilowatts capacity at fifty or sixty volts. The generator regulation is accomplished by varying the pressure on a pile of carbon discs in the field circuit by means of a solenoid which carries the generator current.

"The Newbold device consists of a shunt-wound generator of 2.4 kilowatts capacity at thirty or sixty volts, and a regulator having a field rheostat which is operated by the pull of a solenoid core opposed by an adjustable weight, the action being for any increase in generator current to pull in more resistance in the field rheostat. The solenoid has two windings; one carrying the machine current and the other, which is wound in opposition to the first, carrying the lamp current, so that when the lamps are turned on, the generator output is increased in proportion to the lamp load.

"The Bliss Type F equipment consists of a shunt-wound generator of three kilowatts capacity at thirty or sixty volts, and a regulator which has two permanent resistances in multiple with each other, and in series with the field winding. Each one of these resistances is short-circuited by a carbon-pencil contact. The lower carbons are mounted on solenoid cores. The main winding of the solenoids carries the generator current and the second windings the lamp current. The solenoids thus control the pressure on the carbon-pencil contact and vary the degree of short-circuiting of the permanent resistances in the field circuit; the action being to maintain a constant generator current with an increase when the lamps are turned on. A permanent resistance being cut in series with the lamps when the generator starts to operate.

"The regulation in the Bliss bucker is accomplished by inserting counter-electromotive forces in the field circuit of the generator and in the lamp circuit. The bucker consists of a motor connected across the generator mains and mounted on the same shaft with the bucker proper. This is composed of an armature having two separate windings and two commutators, and is excited by a series field which carries the battery-charging current. The speed of the bucker is practically constant under a load, so that the counter-electromotive force in the field circuit and in the lamp circuit are very nearly proportional to the battery-charging current. It will thus be seen that the principle is to maintain a constant battery-charging current at all times in addition to supplying the lamp load direct from the generator. The current regulation effected is fairly close, but varies considerably for different train speeds, owing to the fact that successive increases in battery-charging current are necessary to cause corresponding increases in the counter-electromotive force in the field circuit. As the counter-electromotive force in the lamp circuit is proportional to the battery-charging current and is not dependent directly on the actual battery voltage, it is evident that variations of battery voltage during charge and from other causes previously mentioned will cause a considerable variation in lamp voltage.

"The Consolidated Type D equipment consists of a three-kilowatt generator at thirty or sixty volts, and the regulation is accomplished by a rheostat in the field circuit which is automatically operated to maintain a constant current with an increase proportional to the lamp load. The current regulation accomplished is very close and is constant for all train speeds. The lamp regulation is maintained with a variation of one to one-and-one-half volts, by means of an automatically operated rheostat in the lamp circuit. A high-resistance electromagnet is connected across the lamp circuit and operates by means of a small motor and suitable mechanical devices to cut in or out resistance in the lamp circuit on a very small voltage variation. This means of regulation is positive and maintains the lamps at normal voltage regardless of any change of conditions in other parts of the system. The only deficiency in this regulation is that its action is not instantaneous. When a considerable number of lamps are turned on or off a few seconds are required for the rheostat to readjust itself.

"An improvement on this regulator has recently been brought out which acts on the principle of a recording ampere-hour meter, and records the charge and discharge of the battery on a paper roll, giving a complete record of the performance of the apparatus as well as indicating the number of hours' charge in the battery at any time. It charges the battery at its normal rate until about twenty-five per cent overcharged, and then automatically cuts out the generator or cuts it down to a very small current, as desired. As soon as the lamps are burned for half an hour the generator is again cut into service. When there is but an hour's charge at the normal rate left in the battery, all lights except an emergency circuit are cut out, and when one and eight-tenths volts per cell is reached the lights are all cut out. The battery is thus charged at its normal rate and is protected from overcharge and overdischarge, which is certain to add materially to its life. No change of adjustment of the generator current is necessary when a car is transferred from a nearly all-daylight run to an all-night run, as the different conditions resulting are taken care of automatically."

An executive session, attended only by active members, was held on Thursday afternoon for the election of officers and the transaction of other business. The former officers and committees were reelected in nearly every case. The present list of the officers and the executive committee stands as follows:

President, A. J. Farrelly, Chicago & Northwestern Railway; vice-presidents, A. J. Collett, Union Pacific Railway, C. W. Bender, Pennsylvania Railroad; Secretary and Treasurer, G. B. Colegrove, Illinois Central Railroad.

Executive Committee—H. C. Meloy, Lake Shore & Michigan Southern Railway; A. C. Terry, "Soo Line; G. W. Murray, Southern Pacific Railway; O. W. Ott, O. S. L.; D. J. Cartwright, Lehigh Valley Railroad; C. R. Gilman, Chicago, Milwaukee & St. Paul Railroad.

A smoker on Thursday evening practically closed the convention, although a number of the members stayed over to visit Milwaukee on Friday, inspecting the factories of the Bliss Car Lighting Company, the Cutler-Hammer Manufacturing Company and the Allis-Chalmers Company, and the shops of the Chicago, Milwaukee & St. Paul Railroad.

The second annual convention of the Association of Car-Lighting Engineers will be held at Chicago, Ill., October 5 to 8, 1909.

Among the railroads represented at the convention were:

Illinois Central, G. B. Colegrove, E. W. Jansen, J. C. McElru, G. M. Crownover, F. G. Colwell, J. M. Barrowdale, A. L. Chapin, G. H. Groce, M. J. Clark; Chicago & Northwestern, A. J. Farrelly, W. S. Berry; "Frisco" System, R. N. Massey, C. A. Pinyerd; Southern Pacific, G. W. Murray; Lehigh Valley, D. J. Cartwright; Big Four, J. E. Gunnesse; B. O. & S. W., C. H. Charlton; L. S. & M. S., J. P. Puette, M. E. Seymour, H. C. Meloy, E. A. Humphrey; Missouri Pacific, R. W. Bowler; Pennsylvania, C. W. Bender, O. H. Davis, J. Cosland, C. Canstad; L. & N., J. R. Smith, S. Y. Culley; Union Pacific, A. J. Collett; "Alton," C. L. Abrams, J. F. Bigelow, C. W. Eisenmann; "Santa Fe," S. W. Everett, F. R. Frost; C., M. & St. P., C. R. Gilman, W. O. Davies, H. J. Frank, E. Hiscox; "Soo" Line, Chester Terry; New York Central, A. McGary; Burlington, Fred McGary, H. A. Gardner; Wabash, W. A. Hopkins; B. & O., J. D. Brown; Rock Island, W. E. Ballentine, G. H. Scott, F. E. Hutchinson; Northern Pacific, W. J. Bohan; Canadian Pacific, J. A. Shaw; C. & E. I., J. H. Burcham; New Jersey, M. C. Kershaw; Pullman Company, N. E. Lemmore; and other Members, W. R. Hungerford, Chicago; Dr. C. W. Gould; C. M. Perkins, Chicago; A. H. Darker, London, England.

The following manufacturers and supply companies maintained exhibits in the hotel parlors or had representatives on hand during the convention:

Westinghouse Machine Company, D. C. Arlington, S. B. Dusinberre, Edgar Lewis, L. L. Johnson; Storage Battery Lighting Company, E. H. Clare, Fred W. Hulme; Consolidated Railway Electric Lighting and Equipment Company, P. Kennedy, L. J. Kennedy, Thomas L. Mount, R. C. Haley, B. E. Erickson, C. A. Lathan, A. O. Jackson; Central Electric Company, J. M. Lorenz, J. E. Ham, H. W. Young, F. R. Bryant, Allen S. Pearl; Willard Storage Battery Company, T. Willard, W. D. Callinan, W. C. Egert; General Storage Battery Company, John L. Jones, S. D. Dixon; Gould Storage Battery Company, Dr. C. W. Gould, William A. Farbayne, J. Eisenwest, George C. Milne, M. R. Shedd, George R. Berger; Electric Storage Battery Company, E. H. Atkin, F. T. Rinder, H. E. Huet, I. B. Entz, H. B. Marshall; Bliss Electric Car Lighting Company, W. L. Bliss, J. T. Dickinson, N. T. Sherman, Louis A. Mann, Edwin Tover, Jr.; Holophane Company, V. R. Lansingh; A. & J. M. Anderson Manufacturing Company, William W. Hincher; Buckeye Electric Company, L. P. Sawyer; National Electric Lamp Association, S. E. Doane, W. F. Bauer, E. D. Strickland, J. R. Crowe, H. S. Hall, R. B. Clark; General Electric Company, F. W. Wilcox, J. Scribner, Henry Schroeder, G. C. Osborn; Western Electric Company, J. H. Delaney; International Electric Meter Company, Julian S. Jackson, W. W. Cheney; Bryan-Marsh Company, J. S. Corby, James B. Darragh; American Distributing Company, P. W. Hood; Columbia Incandescent Lamp Company, J. G. Boyd, C. D. Oldham, A. C. Garrison; Westinghouse Lamp Company, B. F. Fisher, Jr., J. M. Schilling; New York & Ohio Company, William R. Collins; Sunbeam Incandescent Lamp Company, T. J. Rider, Jr.

Wireless Telephone Litigation.

The Radio-Telephone Company of New York, N. Y., which operates the De Forest system of wireless telephony, has filed a bill in the United States Circuit Court, at Trenton, N. J., asking for an injunction restraining the Collins Wireless Telephone Company, of Newark, N. J., from infringing on patent rights granted to John Stone Stone, of Cambridge, Mass., for wireless telephones known technically as "space telephones." The Radio-Telephone Company also asks for an accounting. The De Forest company is operating under the patents granted to John Stone Stone, and these patents, it is asserted, cover the entire field of wireless telephony.

Armour Institute Branch, American Institute of Electrical Engineers.

A very interesting paper on the selection of a railway motor equipment was presented before this branch at a recent meeting by G. I. Stadeker. His method of attacking the problem, although simple, may be interesting to many not directly concerned in this class of work.

Having given certain requirements to meet, such as the weight of equipment, rate of acceleration, and schedule, a number of kinds of motors in use on similar installations may be considered in a preliminary determination of the required motor equipment. The tractive effort is calculated for full load at several gear ratios for each one. If any of these values correspond to the tractive effort necessary to produce the required acceleration these motors may be further considered, and speed-time curves, current-time curves and distance-time curves plotted for several gear ratios for each one, and from these the energy required to make the typical run, and the time of run with each gear ratio is determined. Watt-hours per run and time of run are then plotted against gear ratios. The proper gear ratio is that one which will make the run in the fastest time with the least power input. This should be determined for each motor under consideration and the energy required and time of run compared with similar determinations for other motors. The final choice of motor equipment is the result of this comparison. Having determined the gear ratio with any motor, before proceeding in comparison with other motors, it must be ascertained that the heating will not be excessive. The continuous rating or the service capacity curves furnished by some of the leading motor manufacturers make this possible.

A new system of plotting speed-time curves was described. The formula used in determining the time it will take a train to change its speed from any speed S to any other speed $S + \Delta V = S'$ is

$$t = \frac{M \Delta V}{.01098 A}$$

in which

M = mass in tons,

V = increment by which speed changes,

A = average tractive effort during change of speed,

t = time to change from S to S'.

Substituting a range of values of A, keeping ΔV constant, t is calculated, and the values so obtained plotted against A. Referring to the speed and tractive-effort characteristic of the motor under consideration, the average tractive effort exerted while the train increases its speed from S to S' can be obtained, and the time to complete this change obtained directly from the curve. This method has the advantage of simplicity of application, accuracy and elimination of error in calculation.

Ithaca Section, American Institute of Electrical Engineers.

The first meeting of the Ithaca section of the American Institute of Electrical Engineers for the college year was held October 30. The programme comprised an original paper by J. G. Pertsch on the general subject of "Alternating-current Line Losses." Mr. Pertsch gave a summary of the investigations which have led up to Ralph D. Mershon's latest work, with especial reference to the researches conducted locally by Professor Ryan. An abstract of Mr. Mershon's Atlantic City convention paper was delivered by W. K. Page. This was illustrated by lantern slides made for the occasion. The speaker brought out the essential features of the paper and led up to a very interesting discussion by the members present.

This meeting was the first held in accordance with the plan laid out by the local programme committee for the year. The plan is briefly as follows:

Alternate meetings will be occupied with discussions of the New York and other Institute papers and with addresses by prominent local and out-of-town engineers. One subcommittee, under the direction of Prof. F. Bedell, who is also chairman of the entire programme committee, invites and entertains speakers from outside. The other subcommittee known as the discussion committee, under the direction of L. F. Blume, arranges for the abstracts and discussions. In order that this committee may be familiar with the practical experience of the local members, a canvass of the entire junior and senior classes, comprising nearly six hundred men, has been made. Each student has been asked to write down on a printed form every detail of his practical experience. Then in preparing for a given discussion the committee goes over this record, picking out the names of men who have had experience along the line of the paper under discussion. This feature has already proved of the greatest value and was not very difficult to effect.

The discussion committee intends occasionally to try an original experiment by having different local members impersonate the engineers who have discussed the papers at the main Institute meeting. Each will endeavor to obtain the point of view of the speaker, and will be called upon by the name of the engineer whom he impersonates. Two objects will be gained by this procedure. First, the spirit of the New York discussion will be repeated, and second, the students will become familiar with the points of view of successful engineers.

At the present time there are three members and twelve associates connected with the Ithaca section. The secretary has signed the enrollment blanks for 138 students. Altogether the work starts out with good promise of success, largely increased enrollment and excellent interest.

Sidewalk Lighting of Underground Engine Rooms.

The development of the show engine room, with its enameled brick walls, artificial lighting and attractively arranged power units, has awakened a natural interest in the improvement of conditions which have hitherto been considered hopeless. Whitewash and daylight will work marvels in any place. In city plants in particular it is all too often considered that lighting without artificial means is an impossibility. But as a rule such engine rooms are more or less accessible to the transmission of daylight if proper arrangements are provided. The refracting prism has in many cases solved the difficulty by throwing the light far into hitherto dark and dirty corners. So, also, has the sidewalk-vault light, with its numerous lenses.

The effect of such methods is well shown by an illustration of an engine room situated beneath the sidewalk which recently appeared in *Power and the Engineer*. The room is not only lighted—it is fairly brilliant. The sidewalk construction, which was the work of the Aberthaw Construction Company, of Boston, Mass., consists of a series of circular lenses embedded in Portland cement. In form the lens is flat on top, the under side being cupped to refract the light, and the circumference ribbed to insure a joint with the cement. Twisted reinforcing rods are run between the lenses to give stability to the entire structure. This design provides the most essential features in such a sidewalk—namely, the opportunity to prevent leakage. But years of trial have shown that good workmanship, born of experience, is just as essential as the design in securing a result that is waterproof.

CHICAGO ELECTRICAL SHOW.

FOURTH ANNUAL EXHIBITION, AT THE COLISEUM, JANUARY 16 TO JANUARY 30. THE PROMISING OUTLOOK.

The outlook for Chicago's Fourth Annual Electrical Show, which is announced to open in the Coliseum, Saturday afternoon, January 16, and run until Saturday night, January 30, is the most gratifying in the history of these great trade expositions in America. With the show still two months away, more than seventy-five per cent of the space is sold and the list of exhibitors includes many of the leading electrical concerns of the United States and Canada. Much of the remaining space is tentatively disposed of, and there is every reason to believe that everything available will be under contract before December 15.

Chicago's electrical shows have already made their record. In the face of the so-called financial panic of a year ago the show was arranged and carried through to a point of success far beyond the anticipations of the directors, and the exhibitors as a whole declared the show to be greater in general results than any of the preceding expositions of the kind. This was also in the face of the fact that the directors had the courage to carry out a decorative scheme for the Coliseum, which cost in the vicinity of $25,000. The same idea of decorative arrangement will be employed this year.

While this year's show will be representative of every branch of the electrical field, efforts are being made to make the show still more comprehensive and representative as a whole, particularly along the lines of motor-driven working exhibits. Telephone apparatus and devices will be a leading feature, the telephone interests having contracted for considerable space. In the meantime it is hoped that everything new in the electrical world will be on view and that the show will not only be a trade booster but will be of educational value to the general public. Considering the fact that the Electrical Show represents a field which rolled up a volume of business in the United States amounting to $200,000,000 last year, the importance of the exposition may be estimated. Without an exception the exhibitors of a year ago, notwithstanding the business depression of that period, reported sales that more than paid for the time, money and material that they put in the show.

Among the companies that have already contracted for space are the following: Crane Company, Commonwealth Edison Company, Wagner Electric Manufacturing Company, Federal Electric Company, Cutler-Hammer Manufacturing Company, Pyro One-Light Sign Company, ELECTRICAL REVIEW AND WESTERN ELECTRICIAN, McDowell-Stocker & Company, Shelton Electric Company, Lindstrom-Smith Company, Western Insulation Company, Murphy Electricity Rectifier Company, National Battery Company, Perfection Vacuum Cleaner Company, Chicago Fuse Wire and Manufacturing Company, Electric Appliance Company, the Excello Arc Lamp Company, Kellogg Switchboard and Supply Company, the Stoltz Electrophone Company, Stromberg-Carlson Telephone Manufacturing Company, Mathias Klein & Sons, Telephony Publishing Company, Manhattan Electrical Supply Company, Fort Wayne Electric Works, *Electrical World*, Benjamin Electric Manufacturing Company, *Electrical Record*, Central Electric Company, International Correspondence Schools, *Popular Mechanics*, McRoy Clay Works, National Electric Lamp Association, Chicago Pneumatic Tool Company, Electrocraft Publishing Company, Robbins & Meyers, Appleton Electric Company, United Pump and Power Company, *Popular Electricity*, Chicago Telephone Company, Swedish-American Telephone Company, Westinghouse Companies, Swedish Vibrator Company, Western Electric Company, Electrical Testing Laboratories, *Electric City*, General Electric Company, North Shore Company, Pacific Electric Heating Company, Electric Storage Battery Company.

Homer E. Niesz, under whose management the last two shows have been great successes, looked after the preliminary work of this year's show, but under the orders of his physicians he has been forced to temporarily abandon work. He returned from the New York show last month, was immediately taken ill and remained in bed three weeks. He is now recuperating at Hot Springs, Ark. In the meantime his work as the head of the show has been taken up by John C. Schayer, who is well and properly known in the electrical field. Mr. Schayer will direct the preparations for the coming show until the return of Mr. Niesz.

Block Signals for Indiana Railroads.

The first railroad convention to be held under the requirements of the Indiana law assembled in the State House at Indianapolis on November 10. A hundred or more delegates, representing the superintendents, operating managers and employes of steam railroads operating in Indiana, were present and took an active part in the proceedings. Union B. Hunt, chairman of the Indiana Railroad Commission, in calling the meeting to order, stated that the object of calling the railroad men together was to make a thorough study of railroad accidents and their causes, and to adopt methods to diminish the number of such accidents. The commission would recommend to the incoming legislature that laws be passed prohibiting the construction of any more grade crossings, and that the expense of separating grade at highway crossings and track elevation may be divided equitably. There are 10,000 unprotected highway crossings in Indiana on which about 100 persons are killed annually.

The commission called the railroad men's attention to a section of the transportation law passed by the last legislature, which provides that after July 1, 1909, the railroads in Indiana must be equipped with and have in operation an approved block system for the control of trains. The commission urged immediate preparation for carrying out this work, but it was stated that an extension of time would be granted where it was shown that an honest endeavor was being made to comply with the law. The commissioners stated that the law does not apply to electric roads, but they would recommend that the incoming legislature so amend the law as to require similar action upon the part of the electric roads.

New Subway Plan for New York City.

Joseph Caccavajo, an engineer, has submitted to the Public Service Commission his plan for the building of new subways in New York city. The matter was referred to the Committee of the Whole.

The plan, in brief, is that the owners of property along the line of the proposed subway shall form a company, each property owner taking shares in the company to an extent commensurate with his land holdings. It is estimated that a comparatively small sum would have to be subscribed for each lot owned, and that there would be raised by this means a sufficient amount to build and equip a subway system. It would be necessary to amend the law to permit the adoption of Mr. Caccavajo's plan.

The Fore River Ship Building Company's Yard.

The shipyard of the Fore River Ship Building Company, at Quincy, near Boston, Mass., although opened only a few years ago, has already become one of the most important plants on the Atlantic Coast for the construction of large ships, and it would be difficult to find one equipped more completely and embodying more of everything that is latest and best in engineering practice. Less than eight years old, it has already contributed notable additions to the navy of the United States.

Practically every part of a battleship, that most complicated mass of machinery, is constructed within the seventy-eight-acre enclosure. The Fore River shipyard is not the result of slow development. It has arisen almost full-fledged without the usual early stages of experiment and trial. Only the steel and the gray iron castings are brought into the yard in a semi-finished state. Even the electric equipment of the warships is now being manufactured upon the ground; and the engines, both reciprocating and turbine, are built and finished in the shops.

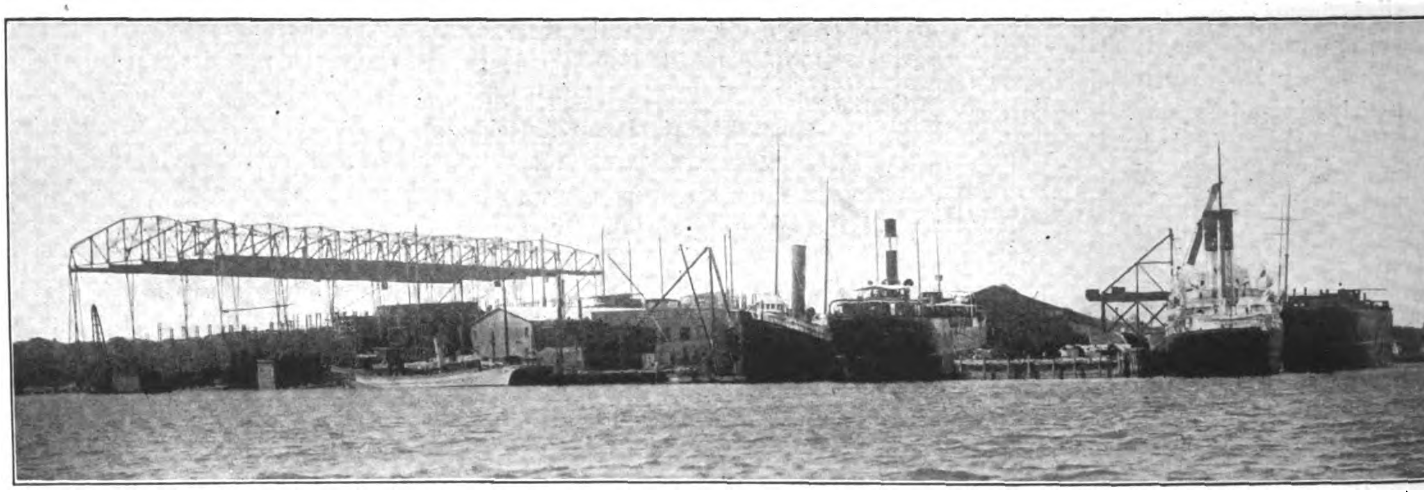
The plant is situated upon ground lying along the Weymouth Fore River, really an arm of Boston harbor and only ten miles from the city. The ground has a frontage of one and three-quarter miles. There are fifteen large buildings and a number of smaller ones, furnishing a floor area of nearly twelve acres. Some idea of the magnitude of the works may be gained from the statement that the normal number of men at work is something over 4,000, and that every conceivable labor-saving device is employed. There are about 275 electric motors for driving machine tools, cranes, etc., besides pneumatic ship tools, steam hammers and hydraulic presses.

The most conspicuous structure on the premises is the "ship house," which is merely a huge steel framework for carrying the great cranes, commanding every spot of the area enclosed and having a clear lift of about 100 feet, sufficient to carry material to any part of large vessels lying on the stocks within. This skeleton building is 490 feet long by 325 feet wide and is divided longitudinally into four bays, each equipped with a crane of nearly eighty-foot span. The spreading girders are not intended to support a roof; the form merely exemplifies an economical disposition of material for carrying the cranes.

Adjoining the ship house is the ship tool house, which is a large building containing practically every known arrangement for shearing, punching and forming plates and shapes into sections of a ship's frame or skin. The tools in this building are admirably arranged for convenience in handling plates of awkward sizes and shapes. The floor surrounding each punch and shear is as free from obstructions as possible, even all motors and wires being kept out of sight, and every large tool being surmounted by a swinging crane, so that the men have free access to the work in hand and are free to guide it in any direction.

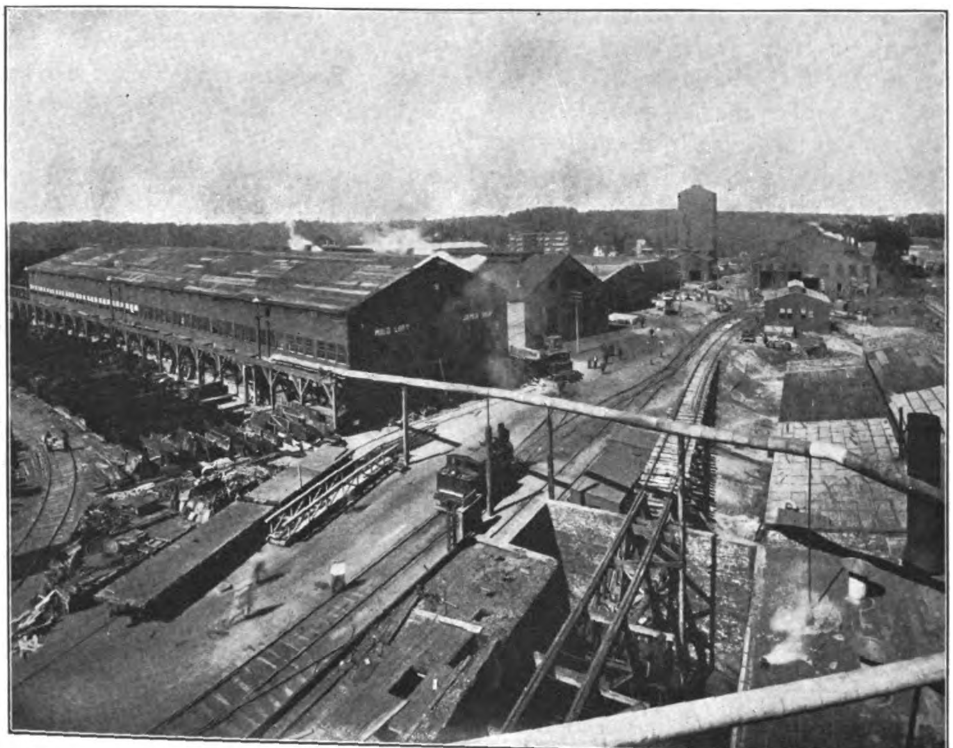
The main machine shop is remarkable for the number of tools of gigantic proportions which it contains. There are huge lathes for turning the crankshafts of the largest battleships, immense boring mills with revolving platforms flush with the floor, great planers large enough to monopolize the entire floor space of an ordinary custom machine shop, and in the side bays smaller tools of all sizes and for all purposes. In one end of the building the great engines of battleships are set up and fitted, later to be taken down and installed in the hulls of the steamers which they are to drive. A portion of the store building is fitted up for the manufacture of electric equipment for the vessels under construction. The pattern shop contains a full equipment of the usual woodworking machinery, the upper floor of the building serving as the mold loft, where the ships' plates are plotted and outlined.

A new blacksmith shop has been added to the plant. It contains some forty fires and a full equipment of hammers. The forge building is the third largest in the United States. Propeller shafts and parts of guns are forced under steam hammers. The annealing plant adjoins the forge. It contains oil-burning heating furnaces and vertical cylindrical annealing tanks for oil baths. There is a saw mill equipped with a large band saw for cutting the timber used in ships, also a brass foundry for casting brass valves and other bronze and brass parts.



VIEW FROM WATER FRONT OF THE FORE RIVER SHIP BUILDING COMPANY'S YARD, QUINCY, MASS.

The power house is centrally located and is a building 162 feet long by 65 feet wide. There are ten 6 by 16 feet return tubular boilers set in brick and operated at 125 pounds pressure. The boilers are fired by hand, and there are no high chimneys, the Sturtevant system of induced draft being employed. This draft apparatus is, with the exception of the main engines and air compressors, the only steam-driven machinery in the entire yard. For driving the machinery of the plant there is one 350-kilowatt generator driven by a horizontal steam turbine; one 300-kilowatt generator direct-connected to a compound condensing engine; and one 200-kilowatt generator also driven by an engine. For operating pneumatic hammers, drills, calkers, etc., used in ship work, there are two compressors, one having a capacity of 5,000 cubic feet per minute and the other delivering 1,000 cubic feet, both being operated by cross-compound engines. All the apparatus of the power house is of very simple construction, only one kind of current being generated for all classes of service—direct current at 240 volts. Current is generated for about 275 motors, varying in size from one-fourth to 100 horsepower, the major portion being supplied by the Allis-Chalmers Company, and also for about 4,000 incandescent lamps and 350 arc lamps.



THE YARD RAILWAY, MOLD LOFT AND BASIN, FORE RIVER SHOP BUILDING COMPANY, QUINCY, MASS.

VIEW IN SHOP OF FORE RIVER SHIP BUILDING COMPANY, QUINCY, MASS.

About seventy-five per cent of the motors are direct-coupled to the tools which they drive. Some of the remainder are belted, and in one or two cases counter-belted to obtain a high speed, this practice being almost entirely confined to woodworking tools requiring a different method of power application. There are a number of special motor-driven tools designed to facilitate ship-building operations. One of these is a counter-sinking machine, consisting of a motor geared to a drill stock which holds the tool, the whole being mounted on a hand barrow, so that the entire apparatus can be rolled over a plate placed in a horizontal position and the tool brought to its work by merely pressing down in the proper positions. While the aggregate load of all the motors in the yard is not far from 3,800 horsepower, the average load upon the generators is only about 2,400 amperes for both power and lighting, or about 800 horsepower. The load varies according to the number of tools actually in operation or in idleness, but the figures here given are a fair illustration of the economy of the system of power distribution and subdivision employed in the yard.

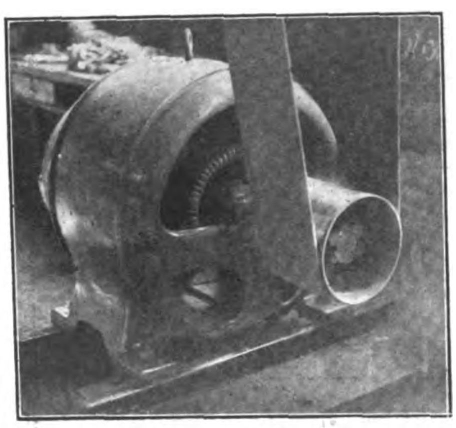
One of the most interesting features of the electric equipment of this shipyard is the system for speed variations. This is the Ward Leonard multiple-voltage system. The generator is operated on the two-wire plan, supplying the highest voltage, 240 volts, and on this voltage are operated all the constant speed motors, the crane motors and the lighting system of the yard. For variations of speed this voltage is divided into three by means of a balancer set located in the engine room and consisting of three similar machines mounted upon a common base. This enables pressures of sixty, eighty and 110 volts to be carried between the various pairs of the four wires. By proper combinations a number of pressures may be obtained, and, with the aid of a small range of shunt field regulation, a large range of motor speeds, the highest of which is six and one-half times the lowest, may be secured.

The current is distributed to the various buildings by means of about 1,000 feet of subway and nearly a mile of pole line. The average center of distribution in each building is about 500 feet from the power-house switchboard, and each shop has its own set of mains coming up through the floor to a distributing board and the feeders are led in various directions to the individual tools. The distributing center of the ship tool shop is placed in a gallery above the main floor, where the control apparatus of the various heavy tools is also located. One attendant standing in a position whence he can see the operations going on in any part of the shop controls all the ma-travel. There is an eight-horsepower parts, such as controllers and regulators, from the machines, where in this particular shop they would be especially liable to injury, to a place of safety. In this shop all circuits are run under the floor and brought to the machines through steel conduits, and there are no exposed wires anywhere in the neighborhood of the machines. In the subway the circuits are run in rubber-covered cables, manufactured by the Standard Underground Cable Company. These are simply fastened to wooden strips, which give sufficient insulation with the low voltage used and the dry atmosphere of the subway. At the center of distribution in the buildings the line is brought up in enameled "electro-duct" tubing, and there the main fuses and switches of the machines are placed.

To the casual visitor in the Fore River shipyard no one feature is more interesting than the great variety and number of electric traveling cranes used to facilitate the handling of material. The great crane which reaches every portion of the plate yard adjoining the steel tool shop is the largest of its kind in the world. It has a span of 175 feet and travels over 1,000 feet of track. The long driving axle is operated by a motor placed in the center of the span, and the lift has a capacity of about five tons. For placing equipment in ships already afloat there are six or more large cantilever cranes and one big folding jib gantry crane, which travels the entire length of the 1,000-foot fitting-out pier. This structure, which is conspicuous in all views of the yard, has no less than seven Allis-Chalmers electric motors. There are three hoist motors: One twenty-five-ton, another seventy-five ton, and one for the ten-ton falls at the end of the boom. The remaining motors are employed, one for crane travel, two for trolley travel and one for hoisting the boom.

In the large machine shop there are three great cranes, two of twenty-five-ton and one of fifty-ton capacity and about eighty-foot span and 520-foot travel. In the ship house are four, having a runway the entire length of the structure, that are capable of lifting a five-ton weight 100 feet vertically and depositing it at any point within the four sections. In the forge and annealing plants one seventy-five-ton and one twenty-five-ton cranes handle the immense ingots, crankshafts and gun parts with ease. Every shop has some form of overhead lifting apparatus wherever there is an opportunity to save time and muscular energy. In fact, the yard is the best possible field for the student interested in the evolution of the workingman from a mere source of energy to the active intelligence which directs and controls the energy developed by machines. It is difficult to find in the entire plant an example of "labor" in the old sense of the word, the mere play of human muscles.

All the large machine tools in which a variation of speed would be desirable are operated by Allis-Chalmers motors on the four-wire multiple-voltage system. In the main machine shop there is one of thirty



TYPE OF ALLIS-CHALMERS MOTOR USED BY FORE RIVER SHIP BUILDING COMPANY.

horsepower mounted upon a 120-inch Niles-Bement-Pond lathe of 108-inch swing; one of twelve and one-half horsepower upon a seventy-two-inch lathe of the same make; four of eighteen horsepower operating sixty-inch Fitchburg lathes; two of twenty-four horsepower driving forty-eight-inch Fitchburg roughing lathes; and four of eight horsepower operating one fifty-inch, two forty-eight-inch and one thirty-six-inch lathe, all of Fitchburg make. In the same shop one fifty-horsepower motor drives a sixteen-foot Niles-Bement-Pond boring mill; one of twenty-four horsepower is on a 120-inch boring mill of the same make; one of fifteen horsepower on a seventy-two-inch Pond boring mill; one of twelve horsepower on a sixty-inch Niles boring mill; one of nine horsepower drives a fifty-inch Niles boring mill, and one of twenty-five horsepower operates a ten-foot boring mill. There are two of four horsepower each on radial drills and two of forty-five horsepower on crank-turning lathes—an interesting machine on which the great cranks used in large ships are braced against distortion by gravity and the cutting-tool travel. There is an eight-horsepower motor for a multiple spindle drill and another of the same capacity for driving an eighteen-inch Niles slotter. A second Niles slotter, twenty-five inches, is driven by an eighteen-horsepower motor and a similar motor drives a Niles milling machine. A Newton cold saw is driven by an eight-horsepower motor. This shop contains a multiplicity of other tools and motors. Those here enumerated comprise only those operated on the four-wire multiple-voltage system.

In the ship tool shop the following machines and motors are operated on the same system: One twenty-four horsepower driving an angle beveling machine; two of four horsepower, each on double-ended shapers; and one of one-and-one-half horsepower to operate a testing machine for bending and breaking strains. In the storehouse is a four-horsepower motor for operating a Newton cold saw. In the electric machine shop two motors of four horsepower drive a sixteen-inch lathe and an American turret lathe, respectively. There is one of three horsepower to drive a thirty-inch drill press; one of one-half horsepower on another drill press, and a second motor of one-half horsepower for operating a coil-winding machine designed on the premises.

Boston Elevated to Increase Capital Stock.

At a special meeting of the Boston Elevated Railway Company it was voted to authorize directors to issue $6,650,000 capital stock at $110 per share to construct and equip the proposed Cambridge subway.

Before passing this vote, however, stockholders had previously authorized the rescinding of the vote of April 13, 1907, which authorized the issuance of $8,000,000 capital stock at a price to be determined by the railroad commissioners.

The $6,650,000 new stock will bring the total stock authorized up to $19,950,000.

The company has petitioned the railroad commission for its approval of the proposed increase.

The issuance of $6,650,000 of new capital stock will give Boston Elevated stockholders the right to subscribe for one new share for each two shares now owned.

Resolutions on the Death of Charles E. Trump.

At a special meeting of the Electrical Trades Association of Philadelphia, Pa., resolutions were adopted on the sudden death of Charles E. Trump, ex-president of the association, which occurred when he reached home shortly after attending the annual meeting of the organization, which was held at the Manufacturers' Club on the evening of November 5. The resolutions were accompanied by a letter from the retiring president, Charles M. Wilkins, addressed to C. Norman Trump, the deceased's son. Mr. Wilkins' letter was as follows:

The sudden death of your beloved father is a great shock to his friends in the Electrical Trades Association, of which he was a member and officer since the organization now more than thirteen years ago. The fact that he attended the annual meeting last evening, when he greeted his friends with cordiality, and his bright and cheerful spirit was so noticeable, makes it difficult for us to realize that he has been called away.

The members of the executive committee of the association have requested me, in their behalf, to convey to you and the members of his family their heartfelt sympathy in this hour of affliction. Your father was a man whom to know was to love, and his loss will be keenly felt by the members of the association and the electrical trade in general. As president for twelve years he endeared himself to his associates for the sterling qualities of his character; in all questions involving its welfare his judgment was sound, and if he erred at all it was in leaning toward the charitable side to the end that injustice should be done to no man.

A copy of a minute adopted by the executive committee, which will be suitably engrossed and sent later, is enclosed herewith, and it but feebly expresses the sense of loss and appreciation of regard for your father.

The resolutions adopted by the association at its special meeting on November 6 were as follows:

The members of the executive committee of the Electrical Trades Association of Philadelphia learn with great sorrow of the death of their former president and associate, Mr. Charles E. Trump.

Mr. Trump served the Electrical Trades Association as a member of its executive committee and president for twelve years, retiring one year ago. At the annual meeting, held on the evening of November 5, 1908, which Mr. Trump attended, he was again honored by election as a member of the executive committee. Mr. Trump's sterling character gained for him the respect and esteem of all with whom he came in contact, and as a mark of our love and regard we unanimously adopt the following RESOLUTIONS:

RESOLVED, That we bow to the will of a Supreme Power, and while grateful for the useful life vouchsafed to our late associate we are yet full of sorrow in our bereavement;

RESOLVED, That we hereby bear witness to the noble manhood of Mr. Trump, whose conception of duty was of the highest, and his aim in life was to be just to all men;

RESOLVED, That we tender our sympathy to the family in this hour of affliction, and that the past and present members of the committee attend the funeral in a body; and, further,

RESOLVED, That a copy of these resolutions be suitably engrossed and sent to his family, and a minute of the same be entered upon the records of the association.

Effect of the Purity of Water on Its Industrial Use.

In connection with an investigation of the quality of surface and underground waters in different parts of the United States, R. B. Dole, of the United States Geological Survey, has made an estimate of the saving that may be accomplished in the production cost of steam by use of a plant for softening water. He says:

"Analyses of Maumee River water, selected as a typical hard water, show that it contains incrusting solids amounting to 360 parts per million, 105 parts of which are suspended mud, etc., and the rest carbonate and sulphate of calcium, with some magnesium, a combination which inevitably forms a hard scale in boilers. If this water were used in a 1,000-horsepower boiler, 100,000 gallons daily would be required. In six working days 1,800 pounds of scale would be deposited in the boiler. In the following figures, the first set estimates the probable excess cost due to the use of bad water, while the second estimates the probable cost after purifying the water. The inference to be drawn from the difference in dollars and cents is obvious:

Cost with use of hard water.

Average coal consumption for 1,000-horsepower boiler, 48 tons a day. 48 tons of coal at $1.50 is $72. Estimated saving in fuel on this water due to use of treated water is 5 per cent. Five per cent of $72 is $3.60 per day, or, for 300 working days	$1,080.00
Cleaning boiler, at $8 per week	416.00
Repairs for tubes, etc	200.00
Boiler compounds	250.00
Coal for raising steam after cleaning, 104 tons at $1.50	156.00
Seven and one-half per cent depreciation on boiler plant costing $15,000	1,125.00
Total	$3,227.00

Cost with use of softened water.

Ten per cent interest and depreciation on softening plant costing $3,500	$ 350.00
Boiler repairs	50.00
Chemicals at 1 per cent. per 1,000 gallons	300.00
Coal for raising steam after cleaning, 16 tons at $1.50	24.00
Five per cent depreciation on boiler plant costing $15,000	750.00
Total	$1,474.00

"The total saving in a single year is, therefore, $1,753, practically half the cost of installing a softening plant."

Remote-Control by Electric Waves.

An interesting apparatus recently constructed by two engineers of Nuremberg, Germany, Messrs. Wirth and Beck, allows, through the medium of electric waves, any levers to be thrown forward or backward, upward or downward, steering wheels or cocks to be turned in a right-hand or left-hand direction and electrical apparatus to be thrown in or out of circuit. In fact, it provides a means of controlling the most varied machines from a distance without there being any material connection between them and the operator. The idea of using Hertzian waves is, of course, not new, says the London *Times* Engineering Supplement.

At demonstrations recently made of this apparatus before the Nuremberg Society of Natural History and other societies the experimental table contained a plant for receiving electric waves similar to those used for wireless telegraphy, connected to the radio-telegraphic controller and the accessory apparatus actuated by the latter.

In another room was installed a radio-telegraphic sending apparatus susceptible of being tuned up to the receiver, and actuated by electromagnetic waves from the apparatus installed on the experimental table. No connecting wires were provided between the sending and receiving apparatus.

Whenever a lever connected with the sending apparatus was adjusted to various positions the apparatus corresponding to these was actuated. A number of electric lamps were thus lighted in any order desired, or in groups, and a small steam-engine was started, reversed or stopped, while electric bells and motors were actuated, powder mines exploded and a revolver fired rapidly.

While torpedoes can be employed so far only over small distances, it is claimed that it will now be feasible to provide them with a far greater driving power, thus directing them toward their goal with safety and from many miles distance.

Land and sea mines have frequently been exploded by electricity transmitted by extensive cables between the operator and each of the mines. The same operation can now be effected through electric waves, that is, by wireless means, provision being made so that only the mine in question is exploded. This firing of mines through electric waves is likely to be adopted advantageously by several branches of industrial activity.

BOOK REVIEWS.

The four books referred to below belong to the well-known series of compact handbooks on various branches of technology published by Dr. Max Jänecke of Hanover, Germany. In each book the elementary principles underlying the subject are first discussed with the aid of simple mathematics only. Practical applications of these principles are then considered. While the Continental practice is mostly dealt with, there is enough of universal interest in each of the volumes to make them of value to German readers anywhere.

"Die Elektrizität auf den Dampfschiffen" ("Electricity on Steamships"). E. Bohnenstengel. Third edition. 124 pages. 4½ by 7 inches. 117 illustrations. Price, in paper, 1.8 marks; in cloth, 2.2 marks.

The aim of this book is to make the captain and other officers familiar with the operation of the electrical devices they have to deal with. After a short introduction on the theoretical foundations the author treats of dynamo-electric machinery, storage batteries, lamps, auxiliary apparatus, distribution systems, conductors, annunciators, telephones, signaling devices, wireless telegraphy and telephony.

"Die Elektrizität als Warmequelle" ("Electricity as a Source of Heat"). Dr. Friedrich Schoenbeck. 104 pages. 53 illustrations. Price, in paper, 1.6 marks; in cloth, 2 marks.

In this book the subject of electric heating is dealt with concisely from all points of view. The laws of electrically developed heat and its units are clearly explained and defined, as is also the calculation of resistance conductors. The various methods of converting electrical energy to heat are described. Applications of electric heating are then considered for cooking and heating in the home and shop, heating of rooms, electric furnaces and their electrochemical products, laboratory apparatus, measuring instruments, electric welding and soldering, ignition, medical and other miscellaneous purposes.

"Handbuch fur den Bau und die Instandhaltung der Oberleitungsanlagen Elektrischer Bahnen" ("Handbook on the Construction and Maintenance of Overhead Line Equipment of Electric Railways"). Arthur Ertel. 336 pages. 294 illustrations. Price, in paper, 4.2 marks; in cloth, 5 marks.

This is a comprehensive compendium on trolley-line construction. The planning and calculation of the working conductor and feeder systems are explained and illustrated. Various types of overhead equipment are described and their construction considered in detail. Special attention is given the layout of curves, crossovers and crossings, the provision for joint use of poles for telegraph or telephone service, catenary construction for high-speed service, trolley construction in tunnels and on bridges, signaling systems, sectionalizing, etc. The maintenance is considered under the sub-heads of periodical inspection, breakdowns in service, repair wagon and tools, regulations. The book is a valuable one for railway engineers, superintendents and foremen.

"Ruhende Umformer" ("Stationary Transformers"). Victor Bondi. 144 pages. 104 illustrations. Price, in paper, 2 marks; in cloth, 2.2 marks.

The fundamental problems relating to transformers form the subject of this book. An excellent idea of its scope may be obtained from the main topics considered, which are the magnetic field, generation of electromotive force, single-phase and polyphase currents, properties of alternating currents, characteristics of single-phase and of polyphase transformers, design and construction of transformers, connections, special transformers, installation of transformers.

"How to Build up Furnace Efficiency." Joseph W. Hays. Chicago. Published by the author. 48 pages. 3½ by 6¼ inches. Supplied by the ELECTRICAL REVIEW AND WESTERN ELECTRICIAN for 50 cents.

In this handy little book the author treats of the most vital problems in boiler-room practice. Methods of firing and draft regulations are discussed in detail as well as all points bearing on coal economy. A careful study of flue gases is made and the author strongly recommends a systematic analysis of the flue gases, preferably with a hand instrument and automatic sampling vessel. The style of the author is so clear that even an ordinary fireman will find much of profit in this book, if he is interested in its title.

Success of Inspection Work.

The Fire Underwriters' committee on fire protection engineering has made a report to companies on the recent meeting of the Western Association of Electrical Inspectors, held in Chicago, October 20, 21 and 22. It is reported that interest in the work of the association has increased, and members are continuing to exhibit a broader conception of the electrical hazard and are seeking the best method of accomplishing its removal. The principal difficulty experienced has been where individual inspectors disagree with existing rules, and when feasible such differences of opinion are made the subject of reports by special committees which are subsequently discussed and the result submitted to the electrical committee of the Underwriters' National Electrical Association, in the form of proposed amendments to the National Electrical Code. The general tendency has been to raise the installation standard rather than lower it. More care is being exercised in discriminating against unapproved materials and devices; members are becoming more familiar with the fire dangers existing in defective electrical fittings through tests carried on during the meetings held in Chicago, these experiments proving the most effective means of impressing upon inspectors the need for careful scrutiny of this detail of the electrical equipment. That the association is meeting, to some extent, the every-day needs of the electrical inspector is evidenced by the large number of applications for membership received from inspectors located in Pacific Coast territory and Canada. The indications are that the work of the organization will be vigorously pressed during the coming year.

Proposed Chicago Building at Alaska-Yukon-Pacific Exposition.

An option for an advantageous site for a Chicago building at the Alaska-Yukon-Pacific Exposition, to be held at Seattle, Wash., in 1909, has been secured by the Chicago Association of Commerce and a special committee has begun the preliminary work of ascertaining the representation desired by merchants of the city.

The building and its maintenance as planned will cost $60,000, although the structure can be enlarged if this scale is found inadequate. It will contain reception rooms, offices and a big lecture room. Only about $25,000, it is believed, will be needed for the building, and the remaining sum is to be devoted to a publicity campaign.

The impossibility of representing even a small per cent of Chicago's industries by an actual display of goods is admitted. Instead, the committee has outlined the plan of installing a lecture platform and an all-day series of moving pictures and stereopticon slides showing how Chicago goods are made, with a lecture demonstrating their qualities.

Frederick Bode, president of Gage Brothers, is chairman of the committee which has the enterprise in charge.

The exposition opens June 1, 1909, and closes October 16.

Tripod for Lighting Fixtures.

By the invention of new devices and the improvement of old appliances the work of wiring a building for electric lights or power has been greatly facilitated and its character decidedly improved. A simple device of this kind has been invented by Edwin A. Emery, of Galva, Ill. It is a tripod for supporting electric-light fixtures, and was patented a month ago. It is designed to lessen the labor of hanging such fixtures and to provide for their ready adjustment, so that they will hang plumb.

The accompanying drawings illustrate the construction of this device. Fig. 1 is an elevation of an electrolier or chandelier secured to a ceiling by one of the new tripods, the canopy being withdrawn to reveal the tripod; Fig. 2 is a detailed plan view of the tripod; and Fig. 3 is a central sectional view thereof. In these drawings, 1 designates the stem of the electrolier and 2 the canopy for covering the tripod 3. The latter is made in two parts, one comprising a plate 3^a having curved arms 3^b converging toward each other and the other consisting of a smaller plate 3^c having curved diverging arms 3^d spaced similarly to the arms of the first part. The arms 3^d normally engage the inner faces of the arms 3^b, and are secured thereto by screws. The passages 5 for these screws in the arms 3^b are larger than the shanks of the screws for the purpose of adjustment. The plate 3^c has a screw-threaded passage 6 through it to receive the stem of the electrolier.

Practice has shown that when a fixture is secured to a plastered ceiling it will nearly always be out of plumb, owing to unevenness in the surface of the plaster. When the ordinary one-piece tripod is used the only way to remedy this is to loosen the screws holding the tripod to the ceiling and wedge it down with washers or pieces of cardboard or other material. This requires time, and at best gives only a botch job when finished. When Mr. Emery's tripod is used, as soon as the fixture is secured to the ceiling, the adjusting screws 4 may be loosened to permit the fixture to plumb itself or be plumbed, after which the screws may be tightened, making a good, firm job.

If desired, the upper or main part of the tripod may be screwed to the ceiling or wall first, and the electrolier or bracket having the smaller part of the tripod screwed upon it, may have its arms inserted between those of the main part and turned until the screws 4 can be put in and tightened. This also makes it convenient if the fixture has to be taken down for repairs, as none of the screws that hold it to the ceiling have to be disturbed.

It has been noticed with the old-style tripod that the wiremen fasten the fixture to it before installing it. When this is done the starting of the screws through the plaster will cause it to crumble and fall down within the canopy, which has

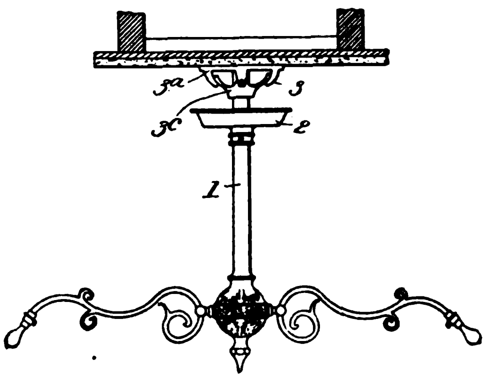


FIG. 1.—ELEVATION OF ELECTROLIER.

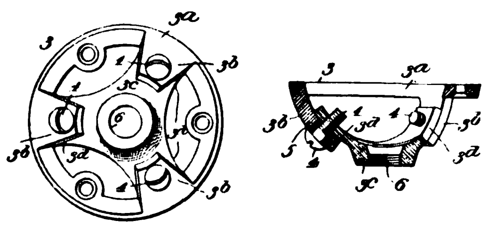
been dropped down on the stem, as illustrated, for instance, in Fig. 1, to permit access to the screws. Then, when the canopy is slipped up into place, the plaster will lodge between the canopy and stem and scratch the casing of the latter, removing the lacquer and causing it soon to tarnish. By employing this tripod



FIGS. 2 AND 3.—DETAIL PLAN AND CENTRAL SECTION OF TRIPOD.

and screwing the upper or main part on first, this can be avoided. Of course, the old style of tripod can be put up first, but in screwing the stem of the fixture into it at least six turns are required, and the wires in the stem are liable to become short-circuited.

Central Electric Railway Association.

The regular bi-monthly meeting of the Central Electric Railway Association, embracing the interurban lines of Indiana and Ohio, was held at Lima, Ohio, November 18. The meeting was marked by excellent attendance and interest, and the subject taken up brought out a more general discussion than has characterized the meetings heretofore. F. T. Carpenter, president of the association, after congratulating the members upon the large attendance, introduced Mayor Becker of Lima, who graciously welcomed the members of the association to the city.

The first topic of the session was "The Possibilities of Electric Lines Hauling United States Mail in Competition with Steam Roads." A number of members who discussed the question testified that from experience in carrying mail upon their lines the proposition had not proved a financial success. It was asserted, however, that the electric lines have not yet had sufficient experience in carrying the mail to decide just what the possibilities of such service might bring forth.

The second subject, "The Claim Department," was presented in an address by Frank Tallmadge, president of the Frank Tallmadge Company of Columbus, Ohio. The definition of what a claim department should be constituted the basis of Mr. Tallmadge's address. He urged that it be properly organized and systematically developed and operated.

"Railroad Crossings" was the subject of a paper presented by W. C. Sparks, superintendent of track and roadway for the Indiana Union Traction Company, Anderson, Ind. The increased weight of interurban cars has caused the engineering department no little trouble to maintain crossings under the constant hammering of heavy locomotives and cars, and engineers and manufacturers have been called upon to build a crossing that will stand up under a service of this sort. Mr. Sparks described the two types of railroad crossings in use and told how they should be constructed and the best plan for keeping them in repair.

The concluding subject of the programme was that of a general discussion of the "Effect of Financial Depression on Earnings of Interurban Roads and Lessons to Be Learned from Experiences of the Last Twelve Months." This discussion took the form of an experience meeting, and the reports varied largely with the local conditions met by each speaker. The extent of the depression during the past few months was not discouraging, and the future, as expressed by those participating in the discussion, is held to be quite optimistic. Great results are in store for the development and increasing operation of electric railways in this country, it was said.

After authorizing the new mileage book to be placed in commission over the electric lines of Ohio and Indiana after January 1, the association set its next meeting for Indianapolis, January 28, and adjourned. S.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

EFFECT OF CONNECTING ELECTROLYTIC DETECTORS IN SERIES AND IN PARALLEL.

This is a communication by M. Jegou to the French Academy of Science. In his experiments he made use of electrolytic detectors with interchangeable anode points, the sensitiveness of which was perfectly well known. The tests made showed clearly that the connection of two or more electrolytic detectors in series is always detrimental to their sensitiveness, a group of detectors so connected being considerably less sensitive than the most delicate one of the group. Care was taken in these experiments to choose the current source, so that the critical tension was always applied, which naturally varies considerably with the number of detectors joined in series.

The investigation of the parallel grouping of the detectors is of much greater interest, as it was shown that the most sensitive one determined the sensitiveness of the group. In this instance the critical tension remained the same. It would seem that the grouping of two or more electrolytic receivers in parallel might be employed with advantage in practice, as a much greater constancy in the sensitiveness of the receiver may in this way be attained; for if the sensitiveness of one of the detectors should accidentally be lowered the general sensitiveness of the receiver will not be at all affected in view of the property mentioned, and in order that this condition may be permanent it is sufficient for only one of the group of detectors to be intact. It is assumed, of course, that care has been taken to use detectors of nearly equal sensitiveness in the group. Furthermore, the connection in parallel has the advantage that the electrolytic points are more seldom burned by powerful waves, emitted by the station itself, for instance. The explanation of the phenomenon seems to be as follows: When the effects on the receiver are extremely feeble, only the most sensitive one of the group of detectors will operate, but when the effects are stronger, the others will operate at the same time. The energy is then divided among the various points of the receivers, and is sufficiently weakened to prevent the burning of the points in many instances.—*Translated and abstracted from La Lumiere Electrique (Paris), October 24.*

THE CONFERENCE ON UNITS AND STANDARDS.

Prof. S. P. Thompson, in a critical résumé of the work of the International Conference on Electrical Units and Standards recently held in London, calls attention to the discrepancies that it was hoped this gathering would eliminate. Thus, while the Chicago Electrical Congress of 1893 had secured international agreement on the definitions of the ohm, ampere and volt, and these units had been generally adopted, some countries had also legally adopted concrete standards not absolutely consistent with the defined units. The real object of calling the conference was therefore to extricate several countries from the difficulties created (a) by the adoption of all three units, instead of two of them, as equally primary; (b) by the confusion between units and standards, and (c) by the discovery of the error of one-tenth of one per cent in the voltage of the Clark cell. In tracing the history of the ohm it is interesting to note that from determinations of the specific resistance of mercury in terms of the absolute ohm made by Lord Rayleigh and others with an accuracy of three or four in 10,000, the length of a column having the prescribed cross-section, mass and resistance is nearer to 106.26, or 106.27 centimetres, instead of 106.3 as adopted in 1893. Mercury columns can now be set up that will not differ from each other by more than a few parts in 100,000. The accuracy with which two resistances can be compared with one another is now far higher than even this, being within three or four parts in 10,000,000. It was expected, therefore, that the International Conference would ascertain with accuracy what the length of the representative column really is, whether 106.26, or 106.27, or 106.3. Until this value should be ascertained by experiments of a refinement comparable to those made in the other lines of advance, any fixing of the final figure could but be arbitrary and not scientific. The adoption of the definition of the ohm as the unit of resistance "which has the value of 1,000,000,000 in terms of the centimetre and second," and then giving its length as 106.300 centimetres, is certainly not consistent, for if the figure 3 is in doubt, what is the use of adding the two zeros.—*Abstracted from the Times Engineering Supplement (London), October 28.*

A CONTRIBUTION TO THE KNOWLEDGE OF THE MERCURY-VAPOR ARC AS A RECTIFIER.

In the rectifier bearing the name of Cooper Hewitt the rectified current flows through the arc in the direction from the mercury to the iron electrode; if the iron electrode is replaced by one of carbon, the rectified current retains the same direction. In experiments made by the author, Dr. Johann Sahulka, at the Electrotechnical Institute in Vienna, in 1894, with the mercury-vapor-light rectifier the alternating-current arc was formed in free air between iron or carbon as one electrode and mercury as the other, and the current flowed in exactly the opposite direction from that which it takes in the Hewitt rectifier, namely, from iron or carbon to mercury. In the Hewitt rectifier the arc is formed in an evacuated space. Doctor Sahulka states that this peculiar influence of air pressure on the behavior of the rectifier is nowhere mentioned in technical literature, and for this reason he calls attention to it and to his work on the effect of the mercury-vapor arc as a rectifier, which was published in the *Zeitschrift fuer Elektrotechnik* in 1894. He continues: "I formed the arc by dipping an iron or carbon electrode into mercury contained in a porcelain vessel and then lifting it a little. The escape of the resulting mercury vapor was prevented by a protecting case with glass walls. In consequence of the great heat an incandescent drop formed at the end of the iron electrode, which would frequently fall off and cause disturbances in the measurements; therefore I replaced the iron rod by a carbon electrode. In tests made between a carbon electrode eleven millimeters in diameter and mercury in free air, with an alternating current of 105 volts and forty-two periods, the rectified current amounted to about sixty per cent of the alternating current. The reason that in my experiments a rectified current is obtained which flows in a direction opposite to that in the Cooper Hewitt rectifier I explain as follows: It is well known that an arc can exist only when the vicinity of the cathode is sufficiently conducting; this requirement does not need to be fulfilled for the anode. In my experiments an incandescent drop forms at the end of the iron electrode, which, when the current sinks to zero, can give off its heat only with difficulty, as it is surrounded by a gaseous medium on all sides. The drop therefore remains at a very high temperature when the current value is zero and sends out conducting vapors, so that its vicinity always remains a good conductor. The mercury is heated to the boiling point when the current reaches its maximum value and sends out conducting vapors; but the heated spot cools very rapidly when the current sinks to zero, as it can easily give off its heat to the uncooled portion of the mercury and the vaporization ceases in consequence of the cooling. When the alternating current flows in the direction from the mercury to the iron electrode it can pass easily on account of the good conducting property of the vicinity of the latter. The mercury is then also vaporized and a heavy current is able to come into existence. But if the current is flowing in the opposite direction it can pass only with difficulty, or eventually not at all, on account of the low conductivity of the cooled mercury electrode. In my experiments, therefore, the rectified current has to flow in the direction from mercury to iron. The conditions remain the same, when the iron electrode is replaced by one of carbon, as the point of the carbon becomes incandescent upon the formation of the arc and cools very little on account of its poor conductivity. The Cooper Hewitt rectifier consists of an evacuated vessel which is provided with a mercury and two iron electrodes. The latter are connected to the secondary terminals of a transformer, while the mercury electrode is joined to the center of the transformer winding through a resistance. In consequence of the good conductivity of the gaseous medium the arc spreads through the entire vessel and the solid electrode is, therefore, heated very little, while the mercury is easily vaporized on account of the low pressure in the vessel, and its vicinity has a better conductivity than that of the solid electrode. If the rectifying effect of the iron-mercury vapor arc were examined in differently evacuated spaces the result would probably be that the reversal of the rectified current takes place when the conductivity of the medium has been so far reduced that the so-called thread-like arc replaces that occupying the entire vessel. But in this case the rectifier can operate only when an incandescent drop has formed at the iron electrode, the vapors from which make its vicinity conducting.—*Translated and abstracted from Elektrotechnische Zeitschrift (Berlin), October 22.*

A DIRECT AND ALTERNATING-CURRENT GENERATING GROUP FOR AN ELECTRIC RAILWAY.

A direct and alternating-current generating group, which was exhibited at the recent Exposition in Marseilles, possesses some original and interesting features. The set comprises a hydraulic turbine coupled to a double-current generator, and is intended to supply current for the Villefranche and Bourg-Madame electric railway in the Eastern Pyrenees. The turbine is built to operate under a head of 400 meters and furnish about 1,100 horsepower at a normal speed of 575 revolutions per minute. Its shaft is horizontal and the buckets are of the Pelton type, although of a special construction. They have the shape of spoons and are all coupled together in a crown bolted to the center disk. Two rings shrunk hot around the buckets insure resistance against centrifugal force. The water enters the turbine in a vertical direction from below. The bronze nozzle is equipped with a hydraulically balanced regulating tongue, which is actuated by a speed governor of great precision operated under oil pressure. The characteristic feature of this governor is that there is no permanent water pressure in the auxiliary motor, but only at the instant when regulation of the angular speed takes place, and its value is always proportionate to the resistance furnished by the turbine buckets. The regulation insured by this apparatus and a 5,000-kilogramme flywheel is so perfect that the speed variation does not exceed four per cent from the normal under a change of load up to fifty per cent. The turbine is provided with a pressure regulator, which opens a compensating orifice in a branch pipe. All the inlet valves of the turbine and pressure regulator are located in the basement in order to avoid any discharge of water in the machine hall, and are operated by auxiliary hydraulic motors controlled electrically from the switchboard. The direct and alternating-current generator is coupled to the turbine by an elastic sleeve. It is designed to furnish direct current at 800 to 850 volts, or three-phase current at 600 volts and twenty-five periods a second. Though rated at 850 kilowatts, it is capable of withstanding momentary overloads of fifty to sixty per cent. The machine is of the stationary inductor type, drum wound, built up of sheets of high permeability and a low coefficient of hysteresis, reducing the losses by heating. The sheets are insulated by paper to prevent the formation of Foucault currents. The armature winding consists of carefully insulated electrolytic copper bars shaped on a form so as to be interchangeable. The direct-current commutator is made of copper segments insulated by micanite. The brushes are of carbon and are sufficient in number to withstand the heavy overloads without undue heating. Auxiliary poles mounted in series with the armature insure a perfect and sparkless commutation with the brushes in a fixed position. A resistance connected in parallel with the winding of these auxiliary poles permits the regulation of the current flowing through it to the proper value. The polyphase current collector consists of six bronze rings, each connected to a fixed point of the armature; the brushes are of copper sheet. The cast-steel inductor has eight main pole projections of thin iron sheets and eight auxiliary poles of cast steel. The poles carry a shunt and a series winding. The turns and size of the copper in the series winding are so chosen that the tension of the machine rises from 800 to 850 volts between no load and full load. The group forms part of the equipment of the abovementioned railway power station, which contains four identical generating sets and also transformers giving a secondary pressure of 20,000 volts. A high-tension transmission line feeds five substations, in which step-down transformers and rotary converters are installed for furnishing direct current of 800 to 850 volts to the third rail. The use of double-current generators at the central station has made it possible to dispense with one substation, since the generators can also feed the third rail direct. A constant pressure at the various feed points for the third rail is insured by a suitable relation between the compound excitation of the rotary converters and the self-induction of the transformers and transmission line.—*Translated and abstracted from L'Industrie Electrique (Paris), October 25.*

INDUSTRIAL SECTION

ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

Indirect Illumination.

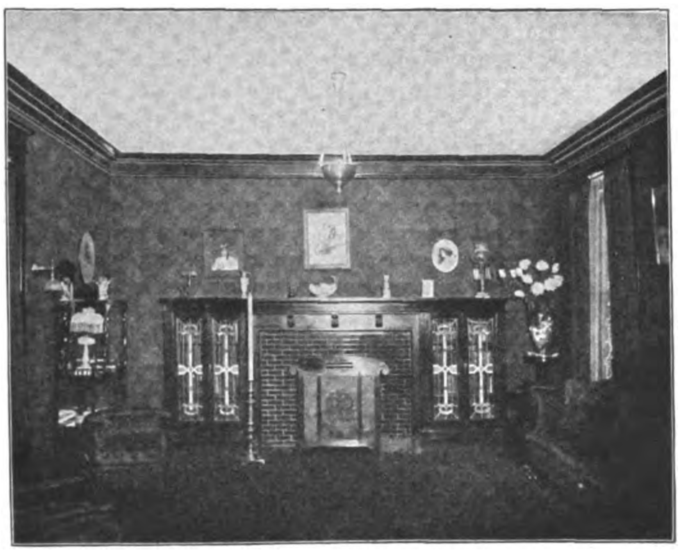
At a recent meeting of the Chicago Section of the Illuminating Engineering Society, Augustus D. Curtis read a paper entitled "Indirect Illumination," and described a system of diffused, reflected interior lighting which has been developed but a short time. This system makes commercially available a practical method of indirect illumination, and has been commented upon very favorably, not only by electrical engineers and central-station men, but by optical experts, who view with alarm any increase in intrinsic brilliancy and the present tendency toward over-illumination.

This system of lighting affords a light of high candlepower at low cost, and a reflecting surface which gives its first reflection of light toward the ceiling without material loss or absorption. Where gas is used, the necessary candlepower and economy are found in using the higher-grade incandescent-mantle burners. Where electricity is used, the high-efficiency tungsten lamp makes it an ideal source of light for this indirect system of lighting.

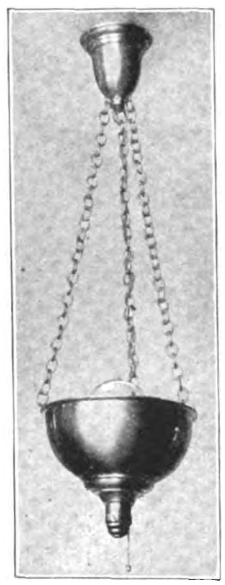
The reflecting surface of the reflector surrounding the lamp or mantle offered no difficulties, as this has been marketed for several years under the somewhat misleading name of "X-ray." Reflectors of this type consist of a single piece of blown glass coated on the outer side with pure silver, giving a reflecting surface of high efficiency. The silvering is protected on the outside by coats of elastic enamel.

The correct shape of the inverted reflector for throwing the rays of light to the ceiling without shadows has been the result of considerable calculation and experimentation. The perfected design is of a bell-shape, and contains peculiar circular and vertical corrugations. Being fire-glazed, the exposed glass surface is easily cleaned with a soft cloth.

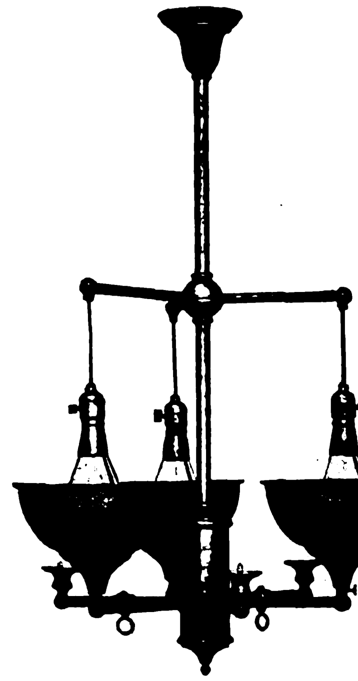
The bell-shaped corrugated, silvered reflector is fitted in a spun-brass casing. On gas fixtures, this casing rests on the base of the mantle like a globe. With electric fixtures the casing can be either suspended by chains or supported from below. A great variety of ornamental designs can be worked out utilizing these units. Where gas or electric chandeliers are already in use, this system of lighting can be readily adopted. Unless the chandelier arms are very heavy, it can be applied where the sockets are pendent, as the arms do not cast any shadows on the ceiling, because the light comes from so many directions that the effect of shadows is neutralized. These lighting units should be used at or near the center of the room, though side lights can be, and have been, used, with satisfactory results.



PARLOR FIFTEEN BY FIFTEEN FEET ILLUMINATED BY A ONE-UNIT FIXTURE CONTAINING SIXTY-WATT TUNGSTEN LAMP.



ONE-UNIT CHAIN FIXTURE WITH TUNGSTEN LAMP, TIP UPWARD.



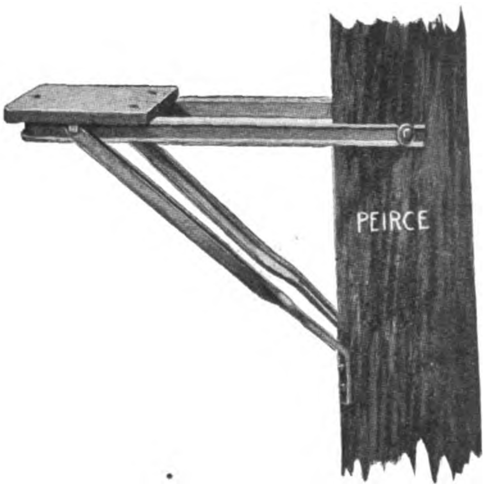
SHOWING HOW THE LIGHTING UNITS CAN BE USED IN MULTIPLES.

Used in Brass Spinning or Casing Shown in Above Illustrations of Lighting Units. SILVER-PLATED REFLECTOR.

A number of installations utilizing this method of lighting have been in use for a some time among professional and business men in their residences and offices. Without exception they are enthusiastic in their praise of the system, and are so impressed with the eye comfort derived that they would not go back to the old system of direct lighting except under protest. These fixtures can be installed in single units or in multiples, either straight electric, straight gas, or combinations of electric and gas. A unit of one reflector and one 100-watt tungsten lamp or a good gas-mantle burner gives a fine illumination in a room up to fifteen feet square. The cost is reasonable, being, on an average, from one-half to one cent per hour.

Pole Seats.

The Peirce Specialty Company, Elkhart, Ind., has developed a number of styles of pole seats to meet all conditions. The braces and frames are made of one-inch by one-half-inch channel steel, and the seat is attached to the pole so that there is no shearing strain on the bolts.



PEIRCE POLE SEAT.

The braces have rugged shoulders on which the frame rests. Five men can safely stand on the cheapest seat made by the Peirce company. It is stated that five men have not only stood but have jumped up and down on this seat. The seats are galvanized and stand the American Telephone and Telegraph Company's test. Galvanized seats are recommended

PEIRCE POLE SEAT, WITH LIVE LOAD OF OVER 850 POUNDS.

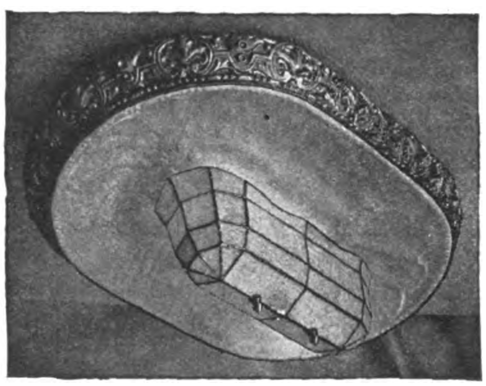
as being cheaper in the long run, and these are shipped ordinarily unless painted seats are preferred.

The accompanying illustrations show the method of attaching the seat. The seat illustrated herewith is thirty-six inches long, and the platform is made of one and one-eighth-inch creosoted cypress, attached to the frame with three countersunk, wax-sealed, galvanized bolts. The other illustration shows the seat standing the test of a live weight of over 800 pounds.

The Extension Diffuser.

The extension diffuser illustrated herewith has been designed to meet the demand for an incandescent fixture embodying the esthetic as well as the scientific principles required for high-grade lighting. It was originally designed by the General Electric Company, Schenectady, N. Y., for use on railway cars, but is especially adapted and recommended for store lighting, and for installation on low ceilings.

As will be noted in the accompanying illustration, the construction of the outfit is remarkably simple; the appearance neat and pleasing. The diffuser can be easily installed on any ceiling where a small flat space can be provided, or it can be suspended from open-work construction. It is readily adapted for recessing, so that the outer edge is flush with the ceiling line.



GENERAL ELECTRIC COMPANY'S EXTENSION DIFFUSER.

The diffuser is held in place by the suspension rods, from which the shade is hung, and the heavy dull finish makes it difficult to distinguish it from plaster. The shade is of white opalescent art glass, strongly bound together, and is specially constructed for rigidity. The glass used in the shade is selected and arranged so as to give maximum diffusion with the minimum absorption of light.

At the present time the extension diffuser is made in two sizes only, the three and six-light; both, however, being adapted for use with tungsten, tantalum or Gem lamps. The larger shades are made in two different styles, known as the deep and the shallow types. The shallow shades are used with lamps of sizes up to and including forty-watt tungsten, forty-watt tantalum, and forty-watt Gem. The deep shades are necessary for use with lamps up to and including 100-watt tungsten, 80-watt tantalum, and 125-watt Gem. Clear-glass lamps only should be used, as the light is thoroughly diffused by the upper and lower shades.

The distribution of light from the extension diffuser is not symmetrical about the vertical axis, as in most lighting units. At angles approaching the horizontal the diffuser emits more light laterally than longitudinally. This is of special advantage in stores when the equipments are installed longitudinally over the center of the aisle. The maximum light being thrown out toward the counters and stock shelves, very little light is thrown directly in the eyes of the customers. The efficiency of the extension diffuser, when compared with other lighting units, is relatively high, especially in consideration of the excellent diffusion.

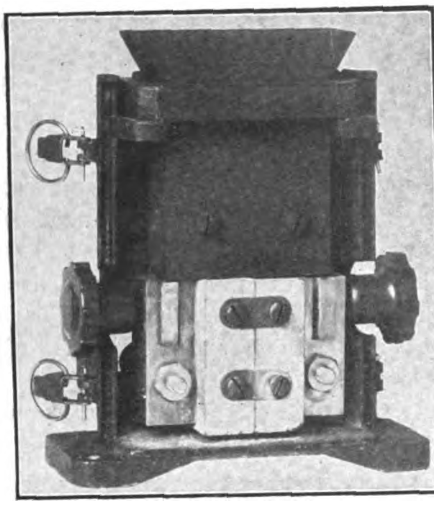
New Orders for General Electric Company.

The General Electric Company reports among recent orders for railway apparatus the following:

The Seattle Electric Company, Seattle, Wash.—Fifty four-motor GE-80 (forty horsepower) car equipments, four 1,000-kilowatt motor-generator sets converting sixty-cycle 13,200-volt current into 600-volt direct current, provided with direct-connected exciters, and four 1,000-kilowatt sixty-cycle 13,200-volt air-blast transformers with blowers, together with the switchboard apparatus. The Denver City Tramway Company, Denver, Colo.—Two 500-kilowatt twenty-five-cycle rotary converters and seven 185-kilowatt oil-cooled transformers. The Sioux City Traction Company, Sioux City, Iowa—Thirty GE-81 (thirty horsepower) railway motors. The Washington Water Power Company, Spokane, Wash.—Twenty four-motor GE-80 car equipments two four-motor GE-73 (seventy-five horsepower) car equipments, with Sprague-General Electric type M control. The Pittsburg Railways Company, Pittsburg, Pa.—One 400-kilowatt engine-driven generator and three 200-kilowatt sixty-cycle rotary converters. The Western New York Construction Company, Buffalo, N. Y.—Eight four-motor GE-204 (seventy-five-horsepower commutating pole) car equipments, with Sprague-General Electric type M control.

Magnetic Blow-Out Fuse Box.

When circuit-breakers were first installed on street cars the motormen regarded them with great favor, and the management has appreciated that they materially reduced the expense for fuses. But gradually the motormen began to find it so easy to throw in the handle of the circuit-breaker that it has become a very frequent occurrence to overload the motor and trip the breaker. This is not only unnecessary, but is frequently a cause of fright to the passengers. The loud report and the flash frequently cause suit for damages to be brought against the company for real or fancied injuries. This careless handling of the controller does more than merely frighten the passengers, for the excessive flow of current causes heavy strains on the motor windings, which may cause injury to the motor. It is thus seen that it has become too easy a matter for the motorman to reset the protective device on his car.



MAGNETIC BLOW-OUT FUSE BOX.

For such reasons large railway companies are equipping their cars with a simple type of fuse in addition to the standard circuit-breaker. This fuse has been recently developed and placed on the market by the Westinghouse Electric and Manufacturing Company, and is of the magnetic blow-out form, which overcomes the objections to the use of the old fuse box.

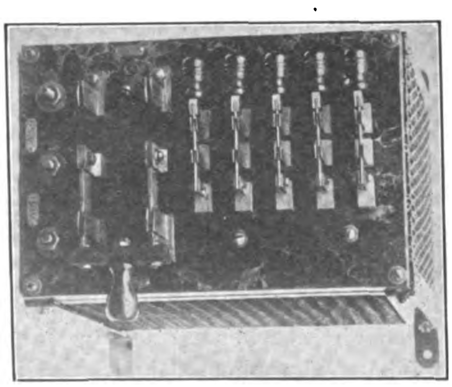
The general design of this fuse box is similar to that of a street-car circuit-breaker, in that it has an all-metal case with the live parts entirely enclosed. It is intended to be placed under the car. The main current is carried by a short copper strip extending down from the terminals in the form of a loop. This loop passes through an arc chute which is supported inside of laminated punchings, thus providing an efficient magnetic blow-out. The blow-out is produced by the ribbon itself without any exterior coils whatever, as a single turn of the ribbon through the iron circuit provides ample magnetism to blow out the arc formed when the ribbon melts. As shown in the illustration, the fuse box is exceedingly compact.

The fuse box will carry 400 amperes continuously without overheating, while the fuses are rated at from 250 to 600 amperes, and are so constructed that they will blow in thirty seconds on 100 per cent overload of this rating. New fuses may be readily inserted by turning the insulating handles on each side of the box without opening the case or using any tools whatever. For the purpose of repairs the sheet-iron front of the box may be readily removed. The arc chute is a single piece and may be readily and cheaply replaced.

This fuse box, while intended primarily for street cars, is not confined to them exclusively, but may be used on industrial motors wherever enclosed fuses would be unsuitable for any reason.

Plating Rheostats for Line Control.

The Ward Leonard Electric Company, Bronxville, N. Y., has designed a complete line of plating rheostats for line control. This is a unique and new design for this apparatus and it offers great possibilities. It is designed for single-voltage and double-voltage control. The accompanying illustration shows a rheostat for line control of the double-voltage type, to be used on a five and ten-volt circuit either on one leg of a three-wire circuit having five volts on each leg or upon the total ten volts. There is a main-line switch (fused when so desired), which, closed in one direction, gives any current from one to forty amperes on ten volts, and when closed in the opposite direction gives eighty amperes on five volts. This gives thirty-one steps of control on either voltage. Each switch with its resistance is designed to be connected across the full five or ten volts, respectively. The various numbers of steps are obtained by using the switches singly or in parallel. As the resistances are designed for the maximum voltage that can be applied upon them, burn-outs are impossible. These rheostats are designed for any capacities and voltages.



PLATING RHEOSTAT FOR DOUBLE-VOLTAGE LINE CONTROL.

Columbia Incandescent Lamp Display.

The accompanying illustration shows a display of incandescent lamps made by the Columbia Incandescent Lamp Company of St. Louis, Mo., in Parlor K of the Grand Pacific Hotel, Chicago, at the recent convention of the Association of Car-Lighting Engineers. This company was represented at the convention by a large corps of salesmen, a list of whom is given in connection with the report of the closing sessions of the convention, which appears on other pages of this issue.

COLUMBIA LAMP DISPLAY AT CONVENTION OF ASSOCIATION OF CAR-LIGHTING ENGINEERS.

Want Seattle Subway Franchise.

Etlinger & Company, of London, and Charles A. Debenditty, of Amsterdam, have applied for franchises to construct eight miles of subways in the business and residence district of Seattle, Wash. The plans provide for a system to cost $6,000,000 and to be completed in less than three years.

A 60,000-Volt Direct-Current Transmission System.

The power transmission system which has been recently installed for the city of Lyons, France, is worthy of note not only from the considerable scope of the enterprise, but also from the fact that it differs from the usual methods employed for this class of work. The source of power is a hydraulic plant which is located on the Isère River, lying at a distance of 110 miles from Lyons. Not only is the distance one of the longest which has yet been employed on the Continent for a power line, but the voltage is also one of the highest, this being nearly 60,000 volts. Instead of using the three-phase system for the power line, this latter is operated on the direct-current system according to the method brought out by M. Thury and used in several cases by the Industrie Electrique firm of Geneva, notably in the St. Maurice-Lausanne power transmission plant. Owing to the progress which has been made it is now possible to use a higher voltage for this method than heretofore, but the present standard of 60,000 volts is not the limit, as it is proposed to double this amount when it comes to increasing the station, and this will be done by grounding the line.

To obtain this high voltage with direct-current generators these are coupled in series. A unit of the station consists of a Piccard-Pictet turbine of 1,600 horsepower, to which are coupled four generators upon the same shaft. These four machines in series give 14,400 volts and they are run at 300 revolutions per minute. As the plant now contains four turbine units of this kind, by coupling all the four units in series we obtain 57,600 volts, which is used directly on the power line. Each of the single generators is a six-pole machine of the Thury type and is rated at 270 kilowatts. It furnishes a current of 3,600 volts and seventy-five amperes. On the exterior these machines resemble the usual form of railway generator, and there are two of them mounted on a common foundation plate with two outer bearings. Electric couplings are used between the two pairs of double generators and between the latter and the turbine.

Where the 57,600-volt power line reaches the city there is a first substation located in the suburbs at Vaulx-en-Velin which receives the direct current in a set of motors and delivers three-phase current. This plant has at present three high-voltage direct-current motors of 800 horsepower each, and they are coupled to three-phase alternators. All the direct-current motors are connected in series, while on the three-phase side the alternators are connected in parallel. From this plant the three-phase current is sent by an underground line to a second substation, which is located in the central district of the city. It is designed to produce direct current for the tramway lines, and to this end it has a number of three-phase motors, each coupled to a 600-volt direct-current generator.

Public Utilities Commission Proposed in Illinois.

In the forthcoming session of the Illinois legislature Sam. A. Ettelson, state senator from the third senatorial district, will introduce a bill creating a state commission of seven members, to have comprehensive jurisdiction over all steam and electric railroads, street railways, electric and gas lighting and power companies, telephone and telegraph systems and other public-service corporations. The bill is based largely on the act that Governor Hughes of New York secured the passage of, through the legislature of that state, creating the two public-service commissions that have become so well known.

Only one commission is proposed in Illinois. It is to supersede the present railroad and warehouse commission, but have greatly increased powers in every way. It is to supervise the issues of stocks and bonds by these companies, the regulation of rates and quality of service given the public, and prescribe methods of accounting and reforms of administration and operation. The plan would limit the power of regulation of public utilities now vested in local civic authorities and is therefore approved by many of the public-service corporations that see in it a method of eliminating many petty burdens now imposed on them by municipal councils and other local officials.

On the other hand, Senator Ettelson's proposal has started a lively agitation among the opponents of any curtailment of home rule, and they point out, as an illustration, the excellent results being secured in Chicago as the effect of the traction-settlement ordinances now being carried out under the direction of the board of supervising engineers. As the legislature does not meet till January the agitation of the subject will doubtless bring out many strong arguments for and against the measure.

Improved Facilities for Northwestern Elevated.

The Northwestern Elevated Railroad has completed its terminal at North Water and North Clark streets, Chicago. It has been built over the tracks of the Chicago & Northwestern Railway from Wells to Clark streets and is used about two hours a day during the morning and evening rush to permit a number of trains to be run without entering the Union Loop. It thus not only relieves the congestion on the loop but provides terminal facilities for the road in case of accident to the Wells street bridge or inability to use the loop. Each of the four elevated railways now has a stub terminal of its own near the loop district for auxiliary and emergency service. The new terminal has two tracks with a loading platform between them and two discharge platforms on the outer sides. It was put into service on November 17, practically two weeks before the schedule time of completion and within three months of the breaking of ground. The Brennan Electric Construction Company had the contract for the entire equipment. The Northwestern Elevated Railroad has just put into service a special funeral train, leaving the new terminal at 1 p. m. daily and running direct to Calvary Cemetery.

Monorail Road for New York City.

The first monorail road for the carriage of passengers in the United States is to be built between Bartow station the New York, New Haven & Hartford Railroad and Belden Point, City Island, and will take the place of an old horse-car line. The Public Service Commission has given permission for changing the motive power, and Bion L. Burrows, president of the American Monorail Company, announces that the construction work will begin soon.

Electricity on Southern Pacific.

Advices from California state that the Southern Pacific Company has made application to the authorities in California for permission to convert its present steam operated roads in Berkeley, Cal., and vicinity, for electric transportation.

The Southern Pacific Company has applied for a franchise for that purpose, and the application states that work will be commenced in four months, and completed within two years at a total expenditure of not less than $2,000,000.

Standards of Technical Publicity.

Under this title, Walter B. Snow, publicity engineer, of Boston, Mass., presents an interesting picture of American methods in a recent article in the *American Exporter,* from which the following is quoted:

"In America, above all other countries, publicity is recognized as the handmaid of business success. The fact is fundamental that no sale was ever made in the wide world unless the buyer first learned that the seller had something to sell. No less fundamental is the fact that no legitimate business was ever based upon the ignorance of its customers.

"The high standard of technical publicity which today prevails in America is the result of relatively rapid development; a token, doubtless, of the insatiable energy of its people. It expresses a recognition of the fundamental principle of all advertising—that in the broadest sense it should be considered as an investment and not as an item of expense. The advertiser should not ask, how much does it cost, but how much does it earn?

"America's leadership in publicity has been marked by the educational feature. This is especially true of advertising to and by manufacturers. The country teems with trade journals devoted to the technicalities of particular trades, and to the details of manufacture and sale. In those particularly devoted to engineering, in the widest acceptance of the term, are to be found the best examples of technical advertising. Here the manufacturer, or perchance the engineer, may speak his own language to men who understand its technicalities. What is more, he may be assured that he will find readers. Rare, indeed, is the case where manufacturers or engineers worthy of the name are not subscribers to one or more journals in their particular field. Such subscribers, particularly among the manufacturers, are also advertisers in some of the trade or technical journals which reach the consumers of their products. As a consequence a considerable number of publications in varied lines pass under the eyes of each manufacturer who advertises. From one class of publications he learns what other manufacturers produce that might be helpful to him in the conduct of his office and shop; from others he is able to judge of conditions in the various industries for which his products are destined.

"All this is entirely independent of the vast volume of advertising in the so-called popular magazines, whose name is legion. Here, also, the educational element in construction and wording of the 'ad' is still pronounced. Though it be less technical, the motif of the advertisement is the same; the illustrations are explanatory; they make clear the design or use of the given article; the description is simple and lucid, it tells the reason why.

"Nowhere else are trade papers prepared and published with such care as in America. From the editorial standpoint the leading engineering papers are of exceptionally high order. The presentation of excellent illustrations, both in the reading and advertising columns, is made possible by the use of high-grade paper and careful printing. The half-tone process of reproduction may therefore be employed without fear that the effect of fine engravings will be lost in the printing. Some papers go so far as to request original half-tones for use in the advertising columns.

"The leading papers maintain staffs of advertising writers at the service of their advertisers without charge. In every way they study to encourage the advertiser to exert his best efforts in the presentation of his products. The result is greater frequency of change of copy than occurs in any other class of journals. So good from a technical standpoint is some of this advertising that readers have been led to collect and preserve it for its educational value."

Wireless Experiments with Balloons.

Radio-telegraphic communication with balloons has successfully been maintained in several instances recently, notably by the Condor, which rose from Brussels and exchanged signals with a station erected on the tower of the Palais de Justice, of Brussels. The aeronauts also easily overheard signals sent from the French military station on the Eiffel Tower. The possibility of such signals had long ago been established; danger was, however, feared from the sparks. The first person systematically to experiment in this line, says London *Engineering*, was Hergesell, who, while cruising on the ocean, sent up unmanned balloons from the ship. The balloons were fitted with small receiving apparatus, tuned to different wave lengths on the different balloons, and the arrangement was such that the signal would open the valve of the respective balloon. Hergesell succeeded in bringing certain balloons down again at will at a distance of ten nautical miles.

Mexico to Double Duties on Lamps.

The department of finance of the Mexican Government has submitted to the Congress a bill which revises and increases the import duties on a number of articles. The duty on incandescent electric lamps is increased from eleven cents per kilogramme, gross, to twenty-two cents per kilogramme, gross. Incandescent electric-light globes are now being manufactured in Mexico, and it is understood that the object in doubling the duty is to protect the new home industry. The bill provides that the duty on machinery and apparatus shall continue at $1.65 per 100 kilos, gross, but the following clause, which will be appreciated by importers of machinery, has been inserted:

"The ensemble of pieces constituting a plant of machinery, in whole or in part, may be imported in separate lots, subject to the rate fixed in this schedule, provided that the department of finance so decides in view of the circumstances in each case, and the requirements laid down by the same department be complied with."

Electric-Lighting Equipment for Automobiles.

Among electrical patents issued on November 3 was one granted to Fred. R. Babcock, of Chicago, which covers a lighting equipment for gasoline and steam automobiles. The device is essentially a miniature train-lighting system, much simplified in detail.

From the standpoint of the motorist, the arrangement serves to turn a small portion of the gasoline used in the engine into electricity, which may be used for lights, ignition and any electrical devices desired, and thus limits the supplies required for the car to gasoline and lubricants. The advantages resulting from the elimination of acetylene and kerosene oil, combined with the well-known superiority of electric lights, indicate that this equipment will prove very popular among the automobile fraternity.

Philadelphia Lighting Contract.

The Philadelphia Electric Company was the only concern to submit proposals for the lighting of the city in 1909. Its figures range from twenty-five to twenty-eight cents a light per night, according to location. There are at present 12,000 electric lights throughout the city. The cost of maintenance for 1909 will be $1,182,791.

Current Electrical News

CONTINENTAL EUROPE.

PARIS, NOVEMBER 14.—The new electric tramway line which has been installed in Switzerland to connect the localities of Schwyz and Seewen is noteworthy from the fact that it is operated upon the three-phase system. The electrical outfit of the line is furnished by the Brown-Boveri firm. Should the line be completed according to the present plans it will run from the latter point as far as the town of Brunnen, which lies upon the Four-Cantons lake. Owing to the high gradients which the road possesses, the three-phase system is an advantage here. Current is supplied from a distant turbine plant at 8,000 volts, forty cycles, and a transformer station located near the traction line serves to reduce the voltage to 500, which is used upon the car motors. For the overhead line the road uses a double trolley wire and the car has two trolley poles mounted on the roof. The motor cars are of the tramway type, with the body mounted on a single truck with two axles. The cars each carry thirty-four persons and with the electric outfit weigh about ten tons. The track is of the standard narrow gauge, one metre.

Some of the mining companies, instead of transporting peat, lignite or a poor quality of coal, are now erecting plants for burning this combustible upon the spot and distributing the power in the form of electric energy. A large plant is now in operation in the north of Italy on this principle at San Giovanni-Valdarno in the Tuscany province. It owns rich lignite deposits in this region, but as the lignite contains forty to fifty per cent of water it became difficult to operate the deposits, owing to the cost of transportation compared with the low heating quality of the material. The company decided to erect an electric plant and a power line in order to utilize the product upon the spot and to deliver current over a wide extent of country. The power plant is built near the mines and the combustible is brought by rail to the furnaces. It is first dried partially and is then burned under the boilers. The latter are of special construction so as to consume the half-dried material, and this was found preferable to a previous drying of the lignite, even though the boiler plant had to be built on a larger scale for the purpose. An automatic feed system is used for the furnaces. In the dynamo room are installed the engine and alternator sets, using Westinghouse three-phase alternators of 1,500 kilowatts. These machines are designed for 6,000 volts and fifty cycles, and they are excited by two 130-kilowatt generators. For raising the voltage there are used Oerlikon transformers of the single-phase type, which are connected in groups of three, in order to furnish the three-phase line current at 33,000 volts. The transformers and high-tension switching apparatus are mounted in a series of fireproof cells, which are closed by iron sliding doors. There are at present five high-tension lines starting from the station. One of these lines has about sixteen miles length and reaches Florence. A second line runs further on for a distance of thirty miles to Prato, and a third line runs to Siena at eighteen miles distance.

In order to secure a supply of current for the city of Seville there has lately been erected a power plant which no doubt has the highest voltage yet used on this side of the water for three-phase current. An eighty-foot head of water is obtained from the Guadiaro stream in the Malaga province, with a supply of 4,000 litres per second during eight months of the year. The station building will contain four principal units of 1,500 horsepower each; at present there are three of these units erected. These are three-phase, 5,000-volt alternators working at 410 revolutions per minute and forty cycles. A bank of transformers raises the voltage for the line to 52,000 volts. The power line for this high voltage is of the most modern construction and, like the rest of the plant, is installed by the Oerlikon firm of Zurich. It runs for seventy-five miles through the provinces of Malaga, Cadiz and Seville, and in the region of the Berrueco mountains it reaches an altitude of 2,400 feet above sea level. For the line there are used 1,550 iron-work poles with wood cross-arms. The poles are spaced 240 feet apart on the average, but a maximum distance of 380 feet is often reached. Some of the longer spans reach as high as 1,400 feet. On the poles there are at present two power lines of three wires each using a five-millimetre wire. Along the line there are three substations besides the Seville station. The latter contains the transformer outfit which is needed for the city supply at 3,500 volts. A. DE C.

GREAT BRITAIN.

LONDON, NOVEMBER 12.—A very voluminous report has been issued by the committee on tramway brakes which was appointed about three years ago by the Tramways and Light Railways Association. This committee was the outcome of a series of serious tramway accidents, due to the failure of the brakes to act, and it has received some assistance from the Board of Trade. As testifying to the complete and thorough nature of the investigation which has been carried out it may be mentioned that particulars were obtained of over 5,000 cars, 3,625 being single truck and the remainder double truck. Sixty of the cars were fitted with regenerative control, all had the hand-wheel brake, nearly 3,000 were fitted with the rheostatic brake, about 1,300 with magnetic track brake, 900 with electric short-circuit brake and 120 had a pneumatic track brake. Particulars are given of the very numerous varieties of brake which were investigated and tested by the committee and the causes of accidents are considered in detail. The conclusions of the committee are that all cars should be fitted with two brakes, one of which should be a power brake, although where the traffic is light and the maximum speed slow both may be manually operated. In all accidents, of course, the human element has been an important factor and it is recommended that on all tramway systems there should be a man responsible for the state of the brakes on every car and that a frequent and systematic examination of all brakes should be made. Probably the most useful portion of the report is the section containing particulars of a very large number of tests upon various brakes and sanding apparatus.

Official statistics just published go to show that there are now 216¼ miles of railway in Great Britain worked solely by electricity and 162 miles partly worked electrically. The corresponding figures for a year ago were 197¼ and 157½ miles, respectively. The energy consumed during the past year amounted to 213,675,447 kilowatt-hours, compared with 159,581,401 for the previous year. It is also of interest to note that there are now eighty-six electric locomotives, 806 motor cars and 1,275 trailer cars in use upon these railways.

The manufacturing firm of Bruce, Peebles & Co., which is the agent in this country for Ganz & Co. of Buda Pesth, and which was forced to go into voluntary liquidation last year, has now been reconstructed and a new company is to be formed with a capital of $1,250,000. Creditors and old shareholders are offered stock in the new undertaking upon certain terms which will involve a considerable loss.

Some British and continental capitalists are reported to have joined hands for the purpose of erecting an electric power station in Fiume, Austria, of a capacity of 36,000 horsepower.

It is confidently expected that a result will be arrived at during next week by the committee now considering the bulk electric supply scheme for London. G.

EASTERN CANADA.

OTTAWA, NOVEMBER 21.—From an engineering standpoint, the Ontario hydro-electric power-transmission line from Niagara Falls, 110,000 volts, is the most important of the power-transmission systems of over 40,000 volts in operation and under construction. Work on this system commenced on the 18th inst.

The Montreal fire and light committee has recommended the City Council to offer the Montreal Light, Heat and Power Company a ten-year contract at the following figures: For arc lamps, $75 per lamp per year; for sixty-five-candlepower incandescent lamps, $36, and $24 for thirty-two-candlepower lamps. The proposal also stipulates that the system of lighting now in use shall be replaced by the most modern ones.

The electrification of the Grand Trunk Railway's workshops at Point St. Charles is the latest development of the company's economic policy. The effect of the introduction of electrical equipment in the shops at Stratford and Battle Creek has been to give the management direct practical proof of just what the advantages of electrifying the larger central shops would be. The power required for the purpose of operating the electric plant will be produced from the company's own turbo-generators from coal that it will transport from the mines.

During the coming week there will be several conferences in Montreal between the directors of the Mexican Light and Power Company and representatives of the London house of Sperling & Co. in regard to the leasing of the company to the Mexican Tramways Company. It is now the general belief that the parties favoring the leasing project with the latter company have sufficient proxies to control the actions of the directors, but in view of all the facts, as reported, it is doubtful if the lease, as outlined, will be carried out over the heads of the strong board of directors, who are opposed to the transaction as being unfair to the power company's interests. Should the majority interests, however, undertake to force this lease on the power company the resignation of the directors of that company will likely follow.

One of the best indications of the growing use of electricity is found in the record of the Shawinigan Water and Power Company of Quebec. At present this company is delivering to the city of Montreal 20,000 electric horsepower. As the power was first delivered in 1903, this shows a yearly increase of about 4,000 horsepower, an amount of energy which would, in many cases, operate the entire industries of a city of considerable size. The Shawinigan Company, with its 350 miles of transmission lines reaching from Shawinigan Falls in various directions, is today one of the most complete electrical systems in the world. The power house of this plant is situated about eighty-five miles from Montreal and the company's development is practically completed for 100,000 horsepower. W.

WESTERN CANADA.

Winnipeg, November 21.—The Manitoba Telephone Commission is now making arrangements with the Saskatchewan government to connect the two government systems at a point a few miles east of Sinclair, Man. At the same time the Alberta government is arranging to make connections with the Saskatchewan system at a point on the boundary between the two provinces. The Kootenay Telephone Company, a newly incorporated concern with a capital of $200,000, announces it will at once commence the construction of long-distance telephone lines through the Crow's Nest Pass and connect with the Alberta system on the boundary line between Alberta and British Columbia. This will give the people of Winnipeg, Man., and Nelson, B. C., and the intervening towns telephonic communication.

According to an announcement made by Hon. Robert Rogers, provincial minister of public works, the rates charged for telephones in Manitoba will be reduced at the beginning of the year. He is also authority for the statement that the profits for the first year of operation of the system under government ownership will amount to $200,000.

Since May last the government of Alberta has added 600 miles of long-distance lines to its provincial telephone system. There are now 1,400 miles of long-distance line under operation by the government and 165 exchanges, against thirty-five in May last. The department of telephones is now planning a number of other lines to be built next year, connecting up the smaller towns and villages in the province.

At Cannington Manor, Saskatchewan, the farmers are organizing for the purpose of building a rural telephone system. Estimates provided by the provincial department of telephones show that a system can be installed at an average cost of $35 per mile, including one telephone per mile. Work will commence shortly.

According to H. N. Ruttan, city engineer, the pumping at the city wells in Winnipeg can be done at a great saving by the use of electricity instead of steam. It is probable arrangements will be made with the Winnipeg Electric Company to furnish the necessary power until such a time as the civic plant at Lac du Bonnet is in operation.

The Dominion Messenger and Signal Company is the name of a new organization in Winnipeg which is applying to the city for the right to receive alarms of all fires by a wire connected with the central fire hall. The company has already secured the privilege of using the conduits of the Manitoba Telephone Commission for its wires. The objects of the company have not yet been disclosed. R.

IMPORTANT DEVELOPMENTS.

ELECTRIFIED OPERATION OF SOUTHERN PACIFIC RAILROAD POSSIBLE—A rumor has been current for some time that the properties of the Great Western Power Company, which were supposed to be allied with the Western Pacific interests, had passed under Harriman control, and that the Southern Pacific's local lines in Alameda County were to be operated by Great Western power, using the plant now under construction at Fruitvale Avenue as an auxiliary. A dispatch from Reno, Nev., declares that the Fleishhackers have secured control of the Truckee River General Electric Company, and that Harriman is behind the Fleishhackers in the deal. The presumption is that the Southern Pacific road from Sparks, Nev., is to be operated by electricity, as it has been hinted a number of times that this would eventually be done. A.

STANISLAUS POWER COMPANY BEGINS OPERATION OF 100,000-VOLT LINE IN CALIFORNIA—Work is progressing rapidly on the new power plant of the Stanislaus Electric Power Company in Tuolumne County, California. The first unit, supplying power in the neighborhood of the plant, was started about a month ago. At present two units, with a capacity of about 13,000 kilowatts, are in operation. The remaining units, which will bring the capacity to 20,000 kilowatts, are now in place, but the final work necessary before they can be started up will take about three weeks more. The transmission line, operating at 100,000 volts, is now in use. Under a temporary arrangement, the power is delivered to the lines of the Pacific Gas and Electric Company at Mission San Jose, which is at present the end of the Stanislaus company's line. It will be several months before the line can be extended into San Francisco, and until that time all the power will be sold to the Pacific company. As soon, however, as the line can be completed, the power will be marketed independently in San Francisco and vicinity. A.

SUIT TO DETERMINE LIABILITY FOR INTERFERENCE OF POWER CIRCUITS WITH TELEPHONE LINES—The case of the Citizens Telephone Company against the Fort Wayne & Springfield Traction Company, filed in the Adams County Circuit Court during the past week, is one of great importance to the electric companies operating in Indiana. Several years ago the commissioners granted a franchise to the telephone company for a right-of-way between Decatur and Fort Wayne. The company put up its poles and wires, which were used successfully for several years. The Fort Wayne & Springfield Traction Company later obtained a right-of-way from the commissioners to run its electric line over the same route, and shortly after the traction line began to operate its high-tension transmission system, it was found that the alternations in the power circuit induced noise in the telephone lines, rendering them useless. The telephone company was compelled to move its lines from two to eight miles from the traction line in order to avoid interference, and for the cost of this the telephone company asks judgment from the interurban company. S.

ELECTRIC LIGHTING.

SLIDELL, LA.—The Slidell Light and Ice Company is to install an electric-light plant.

LINDSAY, OKLA.—The city contemplates issuing bonds to construct an electric-light plant.

MOBRIDGE, S. D.—An electric-light franchise has been granted to E. E. Empey, H. B. Miles and others.

AUSTIN, TEX.—The Board of Regents of the University of Texas contemplates the erection of a power plant.

MAYFIELD, O.—The Mayfield Water & Light Company has increased its capital stock from $10,000 to $20,000.

LITTLE ROCK, ARK.—The Little Rock Railway and Electric Company will expend $75,000 in increasing the capacity of its plant.

MUSCATINE, IOWA.—J. C. Sodini has leased the Electric Park and will convert it into a "White City" amusement park for next year.

GARY, IND.—It is announced that the Westinghouse Electric and Manufacturing Company, of Pittsburg, Pa., will establish a branch factory near Gary. S.

SUPERIOR, WIS.—The Northwestern Lighting Company has been incorporated with a capital stock of $15,000 by E. M. Prindle, Theodore Hanson and Louis Hanitch.

NAUVOO, ILL.—The Nauvoo Electric Light and Power Company has incorporated with a capital stock of $5,000. The company consists of local capitalists.

SANTA CRUZ, CAL.—The City Council of Santa Cruz is working on a proposition to issue bonds for the reconstruction of the municipal electric-lighting system.

ANN ARBOR, MICH.—Coach Yost, of the Michigan football team, has had Ferry Field strung with electric lights and an hour of practice is held every evening after dark.

LA CROSSE, WIS.—The La Crosse Water Power Company announces that it will be prepared to generate current for light and power at the plant at Hatfield by December 1.

SONORA, CAL.—The Tuolumne River Power Company has been incorporated at Sonora, with a capital stock of $500,000, by C. D. and W. M. Shaw, C. F. and F. H. Cross.

TWILLINGATE, N. F.—Frederick S. Palmer of Boston, Mass., has obtained a franchise for an electric light and power plant at Twillingate, which he will install this winter.

EVANSVILLE, IND.—Plans are being made by the Evansville Gas and Electric Light Company for improvements costing nearly $400,000. A turbo-generator set will be installed. S.

LAPORTE CITY, IOWA.—The electric light and water plant was damaged by fire to the extent of $3,000 last week. Fire of unknown origin was discovered at 10 o'clock in the morning.

DOWNEY, CAL.—J. R. Gordon has obtained a franchise for furnishing electric light to the town of Downey. He will install a distributing system, covering a territory eight miles square.

LUDINGTON, MICH.—The Interurban Electric Light and Power Company of Ludington has filed articles of incorporation for a capital stock of $100,000 with the secretary of state at Lansing.

HOQUIAM, WASH.—The Grays Harbor Light and Electric Company, of Hoquiam, will shortly install a large amount of new equipment, making material improvements in the lighting service.

COLUMBUS, OHIO—The Middletown Light and Power Company has been incorporated by B. L. Murphy, Charles W. Elliff, Asa McBride and William Sullivan, with a capital stock of $100,000.

HUSUM, WASH.—An electric-light plant to cost about $15,000 will be installed at Stevenson, in Skamania County, deriving power from Rock Creek. The plant is promised to be in running order by December 15.

SPOKANE, WASH.—Jerome Drumheller has organized a company at Spokane with the purpose of developing 10,000 horsepower with a 500-foot head of water, a short distance above the mouth of the Moyie River. Work has already begun on the development. The power will be disposed of for the development of mining and lumbering in northern Idaho. A.

EBANO, MEXICO—The Mexican Petroleum Company will install a hydro-electric plant in its oil field at Ebano, in the state of San Luis Potosi. The company has an extensive industry at that place.

SCOTTSBURG, IND.—The City Council of Scottsburg has decided to install an electric-light and water works plant. As soon as plans are completed, bids for the installation of the plant will be received. S.

GRAND RAPIDS, MICH.—The illumination of Monroe street by series tungsten lamps, a continuation of the lighting scheme of Canal street, was completed, and the current turned on election night, November 3.

CHESTER, VT.—The local electric light company has contracted with the Claremont Electric Power Company for a supply of power developed by harnessing the Black River by the dam at Cavendish Gorge.

WESTPORT, CONN.—The Westport Light and Water Company is laying plans for a line through Green's Farms to Fairfield, and offers to lay out $10,000 on improvements if the Fairfield contract can be secured.

LOS ANGELES, CAL.—The city of Los Angeles, which is engaged in the construction of an aqueduct, will let contracts next month for a 750-kilowatt generator with the necessary equipment and a number of transformers.

DAVENPORT, IOWA.—Brady Street, between Second and Fifth streets, is to have a special illumination scheme, which is supported by a merchants' association. Iron posts surmounted by incandescent lamps will be used.

RED HILL, PA.—If a franchise can be obtained a power plant will be built in Greenville and lines run to Red Hill, furnishing electric light to both towns. East Greenville has had an acetylene gas plant for a year.

GRANDLEDGE, MICH.—Municipal ownership has been found a failure in Grandledge. At a special election the village has voted to sell its electric-lighting plant to the Commonwealth Light and Power Company of Jackson.

RIVER PARK, IND.—The town board of River Park has granted a fifty-year franchise to the Indiana & Michigan Electric Company, to extend its wires, supply street lights and furnish the inhabitants with light and power. S.

GREENVILLE, CAL.—The Round Valley Power Company is installing a plant near Greenville, where a fall of 900 feet is available. It is proposed to generate 2,000 horsepower, which will be sold for irrigation pumping purposes.

REDWOOD CITY, CAL.—The town of Redwood City is planning to extend its electric-lighting service into several residence towns which have recently been built up in the vicinity, and bids will soon be called in for the necessary supplies.

SALT LAKE CITY, UTAH.—The Wasatch Electric Service Company has filed articles. It has 20,000 shares at $1 each. The officers are: Tony Jacobson, president; Sam S. Porter, vice-president; Rob D. McCreery, secretary and treasurer.

LIGONIER, IND.—Municipal ownership of the electric-lighting system of Ligonier is not favored by the citizens. At a recent election the proposition to own and operate a municipal lighting system was voted down by a majority of 72. S.

CHANDLERVILLE, ILL.—The town of Chandlerville has issued its first bonds since its incorporation, to pay for the new municipal lighting plant, recently purchased for $7,000. The installation of the plant is to be completed by December 1.

OROVILLE, CAL.—H. O. Logue has filed several applications for waterpowers in Plumas County and declares that he will build electric power plants. The locations call for 15,000 inches of water on Nelson Creek, a like amount on Onion Valley Creek and 30,000 inches on the Middle Fork of the Feather River at Bidwell Bar, making a total of 60,000 inches. The water from

Nelson and Onion Valley creeks is to be conveyed through Bald Rock Canyon, a wild and rocky canyon that has never been explored by white men.

QUINCY, CAL.—H. O. Lague has been making numerous water locations in Plumas County, California, and it is now announced that he and his associates will build an electric-power plant. Water to the amount of 60,000 inches has been secured.

IOWA CITY, IOWA—The City Council is taking up the matter of electric lights, and maps, proposals, specifications and all other papers, etc., in the matter will be considered carefully by the city solicitor and others, and the Council will be ready for action next month.

OAKLAND, CAL.—A measure has been proposed to the supervisors of Alameda County for the creation of electric-light districts throughout the county similar to the sanitary districts now in existence, in order to relieve the county of the burden of providing lights upon petition.

SAN FRANCISCO, CAL.—The San Francisco Gas and Electric Company will within a few months house its general offices in a handsome new building. Contracts have just been let for the erection of a six-story and basement structure on Sutter street, between Powell and Stockton.

CUERNAVACA, MEXICO.—A large electric-light and power plant is being built in Cuernavaca by E. Conas, the treasurer of the State. The capacity of the new plant will be 1,600 horsepower. It will be used for lighting the city and supplying the tramway system, which is also the property of Mr. Conas.

WHITE SALMON FALLS, WASH.—Martin and J. T. Thompson are installing an electric-lighting plant at White Salmon Falls, to supply the town and the surrounding country. They are installing a 3,000-horsepower engine, and will have all the necessary equipment on the ground in a short time.

VALE, ORE.—The Vale Light and Water Company of Vale, Ore., has been reorganized, R. C. Carter of Baise purchasing a controlling interest in the company. The new president is authority for the statement that the lighting plant will be overhauled and new machinery installed.

LOS ANGELES, CAL.—Work has just been started on a large electrical plant, which will furnish lighting for the Benson Lumber and Logging Company as well as power for the street railway lines of the South Park & East Side Railway. The plant is being erected by the San Diego Wood Products Company, an offspring of the Benson Company.

TACOMA, WASH.—An ordinance is being drawn up by the city attorney of Tacoma for a municipal power project, the principal feature of which is the erection of a $2,000,000 power plant, with a capacity of 20,000 horsepower, on the upper Nisqually River. The plan includes the construction of a reservoir. The initial expense, according to the present plan, is to be met by a $300,000 bond issue. A.

DENVER, COLO.—A bond issue of $1,500,000 has been authorized by the Southern Colorado Power Company for the extension of its electrical transmission lines to all the principal towns in southeastern and southern Colorado and northern New Mexico. Construction work will at once begin along the line of plans already perfected. The central plant of this company is located at Trinidad, Colo., from which light and power will be supplied to all towns within a radius of sixty miles.

INDIANAPOLIS, IND.—J. W. Broady, of Indianapolis, is at the head of a company of manufacturers of central Indiana, who have selected a site for the construction of a power-generating plant in the coal fields near Sullivan, Ind. It is the purpose of these men to erect and equip a plant for the generation of electric power to be transmitted to Indianapolis, Anderson, Crawfordsville, Marion and New Castle. The completion of part of the plant is expected within the next six months. S.

CLEAR LAKE, CAL.—Representatives of the Clear Lake Railway Company, which is working on a projected electric railway line from Napa Valley to the principal towns of Lake County, and the Yolo County Consolidated Water Company are now in San Francisco, and a consolidation of the two concerns is contemplated. Such a deal would enable the railway company, by erecting a low dam at the outlet of Clear Lake, to store ample water to operate a power plant for its line the year round. A.

EL DURO, MEXICO—The Guanajuato Power and Electric Company, which established a large hydro-electric plant at El Duro, state of Michoacan, a few years ago, and built transmission lines to the Guanajuato mining district and city of that name and to other industrial centers within a radius of 150 miles, is making important enlargements and improvements to its great plant and system. It will have its new high-tension transmission line between Guanajuato and Penjamo finished by January 1. The improvements at the various sub-stations of the company will also be completed and ready for operation at that time. New oil switches for the new 60,000-volt line are also being installed. The section of the new reserve transmission line of the company between Guanajuato and Irapuato was recently finished. George W. Bryant, of Colorado Springs, Colo., is an owner.

OBITUARY.

MR. E. H. MIDDLETON, superintendent of the Chicago South Park electric-lighting system, was electrocuted November 22 in the power house at Fifty-eighth Street and Cottage Grove Avenue by coming in contact with a highly charged wire or bus-bar. Mr. Middleton was forty-five years of age, married, and lived at 5328 Jackson Park Avenue.

MR. JAMES FERGUSON, formerly superintendent of the Brooklyn municipal electric-lighting plant and latterly superintendent of the Safety Insulated Wire and Cable Company of Bayonne, N. J., died on November 15 at his home, 173 Hudson Boulevard, Bayonne, of kidney trouble. He was born in Nova Scotia forty-eight years ago and is survived by his widow, a son and two daughters.

MR. OLIVER WELDON BARNES, a civil engineer, who had been identified with railroad construction work in various parts of the United States for the last sixty years, died of pneumonia on November 14 at his home in New York, N. Y., at the age of eighty-eight years. He was engaged in his profession up to a few days before his death. Mr. Barnes was connected with the Pennsylvania Railroad, and it was he who settled the final location of the road from the Alleghany Mountains to Pittsburg, Pa. In 1885 he was a Croton Aqueduct commissioner, and in 1887 was chief engineer of the New York & Long Island Railroad Company. He was a member of the American Society of Civil Engineers, the Union League Club, of New York; the New England Society, and the Engineers' Club, of Philadelphia. He was born at Hartford, Conn., and at sixteen years of age went to Burlington, N. J., to take up his studies as civil engineer, which he completed in Europe. He returned to this country in 1847, and was appointed an engineer in the first corps which went out from Philadelphia to survey the western division of the Pennsylvania Railroad. He was in charge of the engineering for many railroads, including the Boston, Hartford & Erie. In 1871 he became president of the New York City Central Underground Railroad Company, then authorized to build a line from City Hall to Harlem. In 1872 this company passed to the control of the New York & Montreal Railroad Company. Mr. Barnes is survived by a widow, two daughters and a son. He was buried at Fishkill, N. Y., where he had a summer home for forty years.

DATES AHEAD.

International Independent Telephone Association. Annual convention, Chicago, Ill., December 1-3.

American Society of Mechanical Engineers. Annual meeting, New York city, December 1-4.

American Roentgen Ray Society. Annual meeting, New York city, December 28-30.

Chicago Electrical Show. Coliseum, Chicago, Ill., January 16-30, 1909.

American Association for the Advancement of Science. Annual meeting, Baltimore, Md., January, 1909.

Northwestern Electrical Association. Annual meeting, Milwaukee, Wis., January, 1909.

ELECTRIC RAILWAYS.

MISSOULA, MONT.—W. A. Clark is considering the establishment of an electric street-car line at Missoula. C.

DEADWOOD, S. D.—The Black Hills Traction Company expects to have its new electric-generating plant at Deadwood completed by December 1. C.

MARQUETTE, MICH.—The Ironwood and Hurley traction system, which extends from Jessieville through Ironwood and across the Montreal River to Hurley, is to be extended to Bessemer, Mich.

SEATTLE, WASH.—The Seattle-Everett Interurban electric railroad, operating between Seattle and Hall's Lake, has been absorbed by the Stone & Webster interests, and the road will be completed to Everett at once. A.

FRANKFORT, ILL.—The grading for the electric line of the J. & S. Railway along the twelve-mile stretch from Frankfort to Chicago Heights, will soon be completed. Material for the line and track construction is under way.

KALAMAZOO, MICH.—An electric railroad is to be built between Kalamazoo and Elkhart, Ind. This road was surveyed two years ago and much right of way purchased, but it then was dropped for a time. A syndicate has agreed to finance it.

LAWRENCE, KAN.—At a special meeting of the City Council granted a franchise for local service for an electric line to a company headed by W. R. Stubbs, J. E. Stubbs, A. Henley and C. E. Sutton. The company promises to begin work within thirty days.

EVANSVILLE, IND.—On account of the continued drouth it is now costing the Evansville & Southern Indiana Traction Company $800 per month for water to operate its system between Evansville and Princeton. The water is hauled in tanks to the power house in Fort Branch.

EVANSVILLE, IND.—The work of repairing the power house of the Evansville & Eastern Traction Company, at Evansville, has been completed. During the time the power house was out of commission the company operated its road by a locomotive, maintaining a two-hour schedule. S.

WHEELING, W. VA.—Another trolley line has been projected to connect Wheeling with Pittsburg. The new line will follow the West Virginia shore and will be a much shorter route than any that has yet been proposed. The new road will carry passengers over the existing lines from Wheeling to Chester, when the new line will start, with Pittsburg as the terminus.

SACRAMENTO, CAL.—Since the death of Henry A. Butters, president of the Northern Electric Railway Company, parties interested have proposed a combination of the contemplated Hotaling electric line from a point on the bay opposite Sausalito northeasterly to Sacramento, and the Northern Electric, which now extends from Sacramento to Chico, and which soon will be put through to Redding.

PEORIA, ILL.—Two interurban sleeping cars have been operated for eighteen months by the Illinois Traction Company with such success that more cars have been ordered. The first sleepers were put on as experiments, and the chief objection to them proved to be the noise and vibration caused by the motors and the air pump. These interfered with sleep. The new sleepers are made without these noisy accessories, and are run as trailers.

SPOKANE, WASH.—A meeting of stockholders of the Washington Water Power Company has been called for December 1, for the purpose of authorizing a twenty-per-cent increase of the capital stock, which is now $5,016,300, and an issue of bonds to the extent of $15,000,000. It is planned to expend about $2,000,000 a year for the next few years on improvements and extensions. The company now has a number of electric street-railway lines in Spokane, Wash., an interurban railway and an extensive transmission and distributing system, including stations at Spokane, Post Falls and Ross Park. Another important power station is now under construction at Little Falls, on the Spokane River. A.

FAYETTEVILLE, ARK.—Louis Moulton of Boston has applied for a street-car franchise to connect with an electric railway projected from Siloam Springs to Huntsville, Ark. G. T. Propper of Minneapolis also has a plan to build a belt line connecting with a road to Joplin, Mo. The latter contemplates using an old right of way granted for a steam road from Fayetteville east for a distance of six miles.

TOLEDO, OHIO—Curtis M. Steudell and Valentine H. Sorghner, of Chicago, have purchased the Michigan branch of the Toledo, Ann Arbor & Detroit Railway at forced sale, for $60,000. It is generally understood that about $500,000 has already been spent upon the unfinished project, and that it is worth far in excess of the sum paid by the new owners. It is bonded for about a million and a half dollars, and the bondholders will be heavy losers. H.

ELECTRICAL SECURITIES.

For the first time since election the market last week showed some abatement in speculative and investment activity, and public participation fell off, making for bearish conditions. Business, in general, continues to improve, and although there have been exaggerations of the expansion in some quarters, with consequent disappointment, the usual comment is quite satisfactory and optimistic.

Dividends have been declared upon the following electrical securities: General Electric Company; regular quarterly dividend of $2 per share, payable January 15 to stock of record December 3. Kansas City Railway and Light Company; regular quarterly dividend of one and one-fourth per cent on the preferred stock, payable December 1. Norfolk Railway and Light Company; semi-annual dividend of two per cent, payable December 5 to stock of record November 21.

ELECTRICAL SECURITIES FOR THE WEEK ENDED NOVEMBER 21.

New York:	*Closing.*
Allis-Chalmers common	14
Allis-Chalmers preferred	48⅜
Brooklyn Rapid Transit	53¼
Consolidated Gas	151
General Electric	152
Interborough-Metropolitan common	13
Interborough-Metropolitan preferred	33⅜
Kings County Electric	129

Electric Company of America	10¾
Electric Storage Battery common	41½
Electric Storage Battery preferred	41½
Philadelphia Electric	11⅝
Philadelphia Rapid Transit	22½
United Gas Improvement	91

The directors of the Philadelphia Rapid Transit Company have accepted the resignation of George H. Earle, Jr., as a director.

Chicago:	*Closing.*
Chicago Telephone	128½
Commonwealth Edison	108
Metropolitan Elevated preferred	43
National Carbon common	80
National Carbon preferred	112

PERSONAL MENTION.

MR. FRANK N. JEWETT has been appointed general sales manager of the Wagner Electric Manufacturing Company, with headquarters at the main office and factory in St. Louis, Mo.

For the past three years he has been district manager of the Wagner company, with headquarters in the Marquette Building, Chicago. Mr. Jewett was born in New York in 1870, and was graduated from Cornell University in 1893. After his graduation he was employed by B. W. Payne & Sons, of Elmira, N. Y., manufacturing boilers and engines. He spent two years in the experimental department of this company and one year in the sales department. He then became associated with the West Side Street Railway Company, of Elmira, and constructed its power house. Later he was identified with the firm of Evans, Almirall & Company, of New York, contractors for central-station heating and power plants, and in 1900 opened this company's western office in Chicago, retaining the position of western manager until 1906, when he accepted the position of district manager of the Wagner company. Through his connection with the central-station heating industry Mr. Jewett has a large acquaintance in the electrical fraternity and has made a deep impress upon all with whom he has come in contact throughout his entire career. His great knowledge of the requirements of the electrical industry, and his wide acquaintanceship, render him particularly well fitted to direct the sales organization of this important company.

MR. R. H. HARPER has been appointed chief electrician for the Fort Wayne Knitting Mills, Fort Wayne, Ind.

MR. WILLIAM ROBBINS McGOVERN has been appointed chief engineer of the Wisconsin Telephone Company.

MR. H. S. SALT has resigned as vice-president and general manager of the Dale Company, New York city, to take effect on January 1.

MR. W. C. EGBERT has been placed in charge of the Chicago office of the Willard Storage Battery Company, of Cleveland, Ohio.

MR. J. D. EDMONDS, formerly with the Western Electric Company, at Chicago, has been appointed to a responsible position in the operating department of the Sterling Electric Company, Lafayette, Ind.

MR. GEORGE H. FOLDS, for many years an officer of the Twin City Rapid City Transit Company, of Minneapolis, has been appointed general sales manager for the H. W. Johns-Manville Company, of New York. C.

MR. H. W. KENT, formerly superintendent of the British Columbia Telephone Company, has been appointed agent for the province of British Columbia for the Northern Electric Company. His headquarters are at Vancouver, B. C. R.

MR. JOHN H. JENNINGS, who has been superintendent of the Keene Electric Railroad, at Keene, N. H., has tendered his resignation, intending to go to Columbus, Ohio, to take a manager's position with the Ohio Railway Company.

CONGRESSMAN HENRY A. BARNHART, of Rochester, Ind., recently elected from the Thirteenth Indiana District, has taken a prominent part in the Independent telephone movement in Indiana, and was for a time the president of the Rochester Telephone Company.

MR. J. C. GIBSON, who has been division contract agent for the Central Union Telephone Company, with headquarters at Columbus, has taken charge of the Toledo exchange, succeeding F. Lukenbell, who after taking a vacation will accept a position in another part of the Bell territory. H.

MR. WILLIAM J. BAUGHMAN, superintendent of the Stanley-G.-I. Electric Manufacturing Company, Pittsfield, Mass., who has tendered his resignation to take effect December 1, has the selling agency for the General Vehicle Company of Long Island City, N. Y., manufacturers of auto trucks.

MR. HUGH J. McGOWAN, of Indianapolis, is included among those mentioned to succeed Senator Hemenway in the United States Senate. Mr. McGowan is president of the Indianapolis Street Railway Company, and is also president and general manager of the largest system of interurban lines in the state.

DR. CHARLES SIEMANS recently passed through Ottawa, Ontario, on his way from Japan to England. He has been in Japan making an inspection of the railways of that country for the Japanese Government with a view to their electrification. Referring to the proposal to electrify the Canadian Pacific, Dr. Siemens declared that electricity is bound to supplant steam on the railways. He was particularly interested, in his journey across Canada, to notice the profusion of waterpower along the line of the railway.

PROF. J. J. THOMSON has been honored by King Edward of England by conferring knighthood upon him for his extended investigations of the subject of electrons and corpuscles as well as other researches in experimental physics. Sir Joseph John Thomson, as he is to be known from now on, has held the chair of Cavendish professor of experimental physics at Cambridge University since 1884 and that of professor of physics at the Royal Institution since 1905. He is a fellow of the Royal Society and also has the titles D. Soc., LL. D. and Ph. D. He is president-elect of the British Association and will preside at its meeting next year at Winnipeg, Canada.

MESSRS. O. P. FRITCHIE and W. P. PFAFF arrived in Chicago last week and resumed their journey the next afternoon in an electric automobile, in which they are making a run from Lincoln, Neb., to Washington, D. C., and New York city. They desired to make the run from Lincoln to New York in twenty-one days, a distance of more than 1,800 miles. Mr. Fritchie is the manufacturer of the Fritchie electric automobile. Leaving Lincoln on October 31, the Fritchie made an average of seventy miles a day, striking roads in Iowa that were so deep in mud that in one or two places gasoline cars were laid up waiting for the highways to dry. In one stretch eighty-nine miles was covered in a day.

PROPOSALS.

ARC LAMPS, WINNIPEG, MAN.—F. E. Cambridge, city electrician, Winnipeg, Man., has been instructed to advertise at once for tenders for fifty arc lamps for street-lighting purposes. R.

FEDERAL BUILDINGS AT LAKE CHARLES, LA., ALTON, ILL., AND AMERICUS, GA.—The office of the Supervising Architect, Washington, D. C., will receive sealed proposals until December 26 for the construction (including plumbing, gas piping, heating apparatus, electric conduits and wiring) of the Federal buildings at Lake Charles, La., Alton, Ill., and Americus, Ga., in accordance with specifications, which may be had from the custodians of the respective sites, or at the office of the Supervising Architect.

POSTOFFICES AT NILES AND SAULT STE. MARIE, MICH.—The office of the supervising architect, Washington, D. C., will receive sealed proposals until January 3 for the construction (including plumbing, gas piping, heating apparatus, electric conduits and wiring) of the U. S. postoffice at Niles, Mich., and for the construction complete (except elevator) of the postoffice at Sault Ste. Marie, Mich., in accordance with the specifications, which may be had from the respective custodians of site or from the office of the supervising architect.

ENGINEERING SOCIETIES.

ELECTRO TECHNIC CLUB, FORT WAYNE, IND.—The Electro Technic Club, of Fort Wayne, Ind., has announced its programme for 1908-09. A number of prominent men will address the club members on a variety of interesting subjects. The first meeting, held on November 17, was addressed by Prof. C. E. Reed, of the Case School of Applied Science, Cleveland, Ohio, on "Electrical Measuring Instruments." On January 5, E. A. Barnes, superintendent of the Fort Wayne Electric Works, will read a paper on "A Century of Steam."

TELEPHONE AND TELEGRAPH.

SYLVAN, WIS.—The Mill Creek Telephone Company has been incorporated with a capital stock of $3,000.

BEACH, N. D.—The Golden Valley Telephone Company will soon begin installing a telephone system here.

ELLENSBURG, WASH.—The Ellensburg Telephone Company has been incorporated with a capital stock of $10,000.

BOVEY, MINN.—The Mesaba Telephone Company has been granted a franchise for a local exchange at Coleraine and Bovey and will install at once.

COTTONWOOD GROVE, NEB.—The Cottonwood Grove Mutual Telephone Company has been incorporated with a capital of $700 by John Henry and others.

IOWA CITY, IOWA—The Johnson County Telephone Company of this city has reorganized and contemplates the expenditure of about $35,000 in improvements.

ATLANTA, IND.—The Aroma Farmers' Telephone Company, of Atlanta, Hamilton County, has incorporated to build a telephone exchange and system. Henry Carpenter, J. G. Swift and S. E. Billhymer are incorporators.

B. F. Jacobson of Bella Coola, B. C., is making arrangements for the construction of a rural and local telephone system in and around Bella Coola. Construction work will commence as soon as the necessary supplies have been obtained. R.

ROCKWELL CITY, IOWA—P. C. Hoeldoegel of this city, president of the International Independent Telephone Association, has expressed his opinion that the independent telephone companies in the state of Iowa will spend more than $6,000,000 in improvements during the coming year.

FERGUS FALLS, MINN.—The Council of Fergus Falls, Minn., has named a committee to consider the matter of installing a municipal exchange. The Northwestern Telephone Exchange Company had proposed to rebuild the local exchange and raise the rates, and this aroused the idea of a municipal movement.

PERKINSVILLE, IND.—The Farmers' Telephone Company, of Perkinsville, has been organized and will install a local exchange, extending the lines to Frankton, New Lancaster, Elwood and Noblesville. Arrangement has been made with the Central Union Telephone Company for toll-line connection. Charles Harvey, of Elwood, is president of the new company, and F. E. Haworth is secretary.

CINCINNATI, OHIO—The Cincinnati & Suburban Bell Telephone Company has decided to increase its outstanding capital through the issuance of $282,500 treasury stock. The new stock will be given to stockholders at par at the ratio of one share for every twenty-four held. The books close December 14 and the new stock will be allotted on January 4. The present market value of the stock is 175.

EVANSVILLE, IND.—A convention of representatives of the Cumberland Telephone Company and associate companies was held in Evansville November 12. About 100 officials connected with the Cumberland system from southern Illinois, eastern Kentucky and southern Indiana cities were present. J. C. Symmes, superintendent of the Nashville-Evansville district, called the convention to order. During the afternoon session George B. Hall, superintendent of the Evansville-Louisville district presided. After a protracted discussion of a number of questions relating to special features of telephone management and operation the closing address was made by General Manager Leland Hume, who expressed keen appreciation and satisfaction over the attendance and success of the meeting and predicted its results would better the service of the entire system. S.

EDUCATIONAL.

CLARKSON SCHOOL OF TECHNOLOGY—The trustees and faculty of Thomas S. Clarkson Memorial School of Technology, Potsdam, N. Y., announce the founder's day exercises and twelfth anniversary, on Tuesday evening, December 1, in the assembly hall, at 8 o'clock. The founder's day address will be delivered by Samuel Wesley Stratton, director of the Bureau of Standards, Department of Commerce and Labor, Washington, D. C.

INDUSTRIAL ITEMS.

THE WESTERN ELECTRIC COMPANY, Chicago, will open headquarters in Minneapolis at 114-122 Third Street N. on December 1.

THE UNIVERSAL ELECTRIC STORAGE BATTERY COMPANY, Chicago, announces that its factory and general offices have been merged and that the address of both hereafter will be 65 North Peoria Street, Chicago.

THE JENNEY ELECTRIC MANUFACTURING COMPANY, Indianapolis, Ind., has increased its capital stock from $450,000 to $600,000, and has notified the Secretary of State that the place of business and plant will be removed from Indianapolis to Anderson.

THE WESTERN MACHINE COMPANY, Indianapolis, Ind., has incorporated with a capital stock of $60,000 to establish a plant to manufacture engines, boilers, machinery, tools and electrical and mechanical appliances. George J. Schlotzauer and C. H. Scholl, directors.

THE FORT WAYNE ELECTRIC WORKS, Fort Wayne, Ind., through James J. Wood, announces that since the election $150,000 worth of orders has been booked. The company is increasing its force and facilities gradually, and soon expects to be working beyond its old schedule.

THE METROPOLITAN ELECTRICAL SUPPLY COMPANY, Chicago, Ill., announces that it has on hand a good supply of electrical toys and novelties for the holiday season. Special catalogues devoted to these specialties will be sent to those interested in this line upon request.

THE COLUMBIA INCANDESCENT LAMP COMPANY, St. Louis, Mo., issued a special bulletin under date of November 16, covering the line of special lamps for train-lighting purposes. This bulletin was prepared especially for the convention of the Association of Car-Lighting Engineers, held in Chicago last week.

THE WAGNER ELECTRIC MANUFACTURING COMPANY, St. Louis, Mo., announces that the Wabash Railroad Company has awarded it a contract for supplying the Fort Wayne, Ind., locomotive repair shops throughout with Wagner polyphase motors. Motors of from ten to forty horsepower capacity constitute this order, and they will be used for driving all kinds of machine tools.

THE MASSACHUSETTS CHEMICAL COMPANY has recently established new quarters for its Boston office at 185 Summer Street, opposite the South Station and across the street from its old location at 170 Summer Street. E. W. Furbush, general manager of the company, usually spends the mornings at the factory at Walpole and the afternoon at the Boston office. Louis O. Duclos, the general sales manager, will make his headquarters at the new offices.

THE CROCKER-WHEELER COMPANY, Ampere, N. J., announces that another large manufacturing plant, the Estey Organ Company, Brattleboro, Vt., is to install electric drive throughout its works. The company has just placed with the Crocker-Wheeler Company an order for fifty-seven induction motors, ranging from one-half to seventy-five horsepower, together with seven transformers and a switchboard. Current will be purchased from the Connecticut River Power Company.

THE SOUTHERN ILLINOIS ELECTRIC COMPANY, East St. Louis, Ill., announces that it has taken over the business of the American vibrator. During the four years this vibrator has been manufactured about 6,000 have been sold. The American vibrator is constructed to produce rotary vibration and has a regulating screw which enables any one of six speeds to be applied. Its efficacy is based upon the principle of producing perfect blood circulation to restore health, in the treatment of nervous diseases, rheumatism, lumbago and numerous other complaints. Since October 1 the Southern Illinois Electric Company reports that it has sold 260 machines and orders are coming in rapidly from all parts of the world. The company is sanguine of a decided increase in the next few months and these sales, in addition to its electric railway supply, lighting and contracting business, enable it to report prosperous conditions.

THE MINNEAPOLIS STEEL AND MACHINERY COMPANY, Minneapolis, Minn., has secured the contract to install a new power plant for the Manhattan City and Interurban Railway Company, of Manhattan, Kan. The installation will include an eighteen by thirty-six inch heavy-duty Twin City Corliss engine, two sixty-six-inch by eighteen-foot horizontal return tubular boilers, one 200-kilowatt generator, together with switchboard, feed-water heater and purifier, boiler-feed pump, etc.

THE BROWN HOISTING MACHINERY COMPANY, Cleveland, Ohio, manufacturer of automatic hoisting and conveying appliances, has issued a new catalogue, which covers thoroughly its well-known products in this line. "Brownhoist" grab buckets for handling coal, ore, limestone, etc., are pictured in use on many different types of machines. The "Brownhoist" single-rope buckets for application to existing machines having but a single-drum engine are also described and illustrated, and automatic dumping tubs, shovel buckets, etc., are shown.

THE CENTRAL ELECTRIC COMPANY, Chicago, Ill., is distributing a new folder describing Type B knife switches which conform to the National Electrical Code standard. A complete list is given of the current capacities, combinations and prices. Another folder illustrates the use of the Matthews guy anchor, showing the method of placing the anchors in constructing pole lines. An eight-page circular issued by the company describes the construction, application and installation of the new General Electric multi-catch sockets. Several advantages are claimed for these sockets over the older forms.

THE GENERAL ELECTRIC COMPANY, Schenectady, N. Y., has prepared a number of little folders and fliers telling about its low-voltage and miniature lamps. One of these that is particularly seasonable describes decorative lighting outfits. The use of these outfits is certain to increase so long as lights are used in connection with Christmas greens, because of the ease with which these outfits can be installed, and, above all, the safety with which they can be used. General Electric outfits are made in sizes containing from eight to thirty-two lamps, and may be connected to any lamp socket by means of the standard attaching plug. Full description and prices are contained in folder No. 3710.

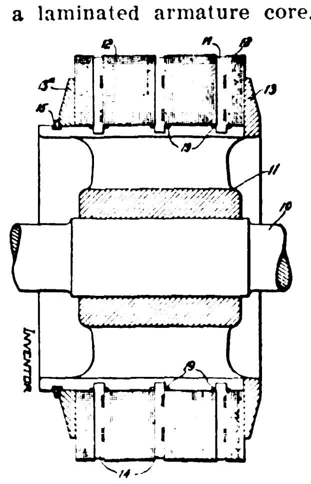
THE WARD LEONARD ELECTRIC COMPANY, Bronxville, N. Y., has issued catalogue E1, covering Ward Leonard circuit-breakers of single-pole types, in capacities up to and including 150 amperes. Although these single-pole overload circuit-breakers have but one handle they consist of two switches in series, so functionally related that the circuit cannot be held closed when an overload or short-circuit exists. Underload and no-voltage release circuit-breakers are shown for battery and motor protection. The catalogue announces that Ward Leonard circuit-breakers received the gold medal prize at the Paris Exposition, among circuit-breakers from all over the world, and that they received the highest award for exhibit at the Columbian Exhibition.

RECORD OF ELECTRICAL PATENTS.

Issued (United States Patent Office) November 17, 1908.

903,826. MANUFACTURE OF METAL-FILAMENT LAMPS. William C. Arsem, Schenectady, N. Y., assignor to General Electric Company. Filed March 16, 1907. The method of protecting a filament from deterioration in the presence of an electric arc consists of locally applying a jet of reducing gas enveloped in a jet of inert gas.

903,829. DYNAMO-ELECTRIC MACHINE. Bernard A. Behrend, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Filed January 31, 1906. Relates to the construction of separators between the sections of a laminated armature core.



903,829.—ARMATURE CORE SEPARATORS.

903,842. EMERGENCY TRAIN-STOPPING DEVICE. Philip Conniff and Franklin A. Pierce, Washington, D. C. Filed January 31, 1908. A circuit closer includes relatively movable contacts and a weighted member carrying the movable contact.

903,860. INCANDESCENT LAMP. John W. Howell, Newark, N. J., assignor to General Electric Company. Filed November 17, 1906. This method of sealing a tungsten filament to a conductor consists in drawing an arc from the end thereof to enclose the filament, the operation being effected within a protective envelope of carbon dioxide and in the presence of illuminating gas.

903,861. ARC LAMP. Charles C. Hughes, Philadelphia, Pa. Filed October 3, 1906. A thermo-expansive alloy member consists of 57½ per cent copper, 42 per cent nickel and one-half of one per cent lead.

903,871. ELECTRIC TELEGRAPHY. Isidor Kitsee, Philadelphia, Pa., assignor of one-half to William J. Latta, Philadelphia, Pa. Filed July 8, 1905. A cable telegraph system is provided with means for impressing alternate positive and negative impulses of practically uniform duration upon the cable.

903,875. SYSTEM OF ELECTRICAL INSULATION. Fred M. Locke, Victor, N. Y. Filed March 20, 1907. A modified suspension-type insulator consists of several petticoated insulators connected by supporting ties leading from the bottom section of each insulator to the top section of the one above it.

903,881. COMMUTATOR NECK OR LEAD. Ashley P. Peck, Milwaukee, Wis., assignor to the Bullock Electric Manufacturing Company. Filed November 9, 1905. The lead is composed of a number of strips of sheet metal fastened together, each strip being corrugated lengthwise.

903,892. FLUID-PRESSURE SYSTEM. William F. Schneider, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Filed April 29, 1907. An electrically controlled air-compressor system.

903,898. AUTOMATIC INDICATOR FOR TELEPHONES. Richard Sedgwick, Richmond, Ind. Filed July 29, 1907. An automatic telephone is provided with a series of figures to indicate the number which a person has called.

903,905. AUTOMATIC RAILROAD GATE. Eugene C. Smith, New York, N. Y., assignor to Lawrence S. Folger, New York, N. Y. Filed May 28, 1906. A motor lowers the gate when the track circuit is closed by the approach of a train.

903,923. METHOD OF AND APPARATUS FOR RELIEVING WIRE CIRCUITS OF ELECTROSTATIC REACTION CURRENTS. Nathaniel G. Warth, Columbus, Ohio. Filed September 16, 1907. A number of composite electromagnetic coils connect the circuit in multiple with the ground at intervals equal to half the maximum length of such a circuit capable of good transmission without a coil applied to it.

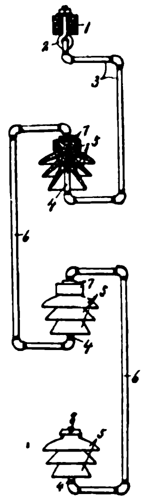
903,927. DRAWBRIDGE CIRCUIT CONTROLLER. Frederick A. Wendler, Elizabeth, N. J., assignor to the Hall Signal Company. Filed May 17, 1907. An electric coupling comprises two separable members adapted to have sliding longitudinal engagement with each other.

903,939. ANODE. Robert J. Wisnom, Virginia City, Nev. Filed May 7, 1907. Consists of a set of rods that can be connected by means of molten metal.

903,945. ELECTROMAGNETIC CLUTCH. Heinrich Ast, Vienna, Austria-Hungary, assignor to Vulkan Maschinenfabriks-Actien Gesellschaft, Vienna, Austria-Hungary. Filed June 15, 1906. One member contains a coil depressed into an iron rim.

903,951. PROCESS FOR THE ELECTROLYSIS OF LIQUIDS. Jean Billiter, Aschersleben, Germany. Filed August 3, 1908. The liquid is fed to the upper one of superposed electrode chambers that are separated by a diaphragm.

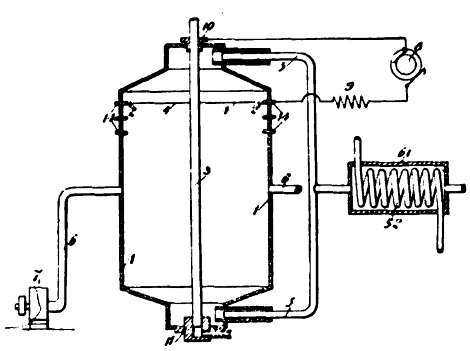
903,966. LAG INDICATOR. William H. Freedman, Burlington, Vt. Filed June 13, 1903. Renewed May 9, 1908. A phase indicator has a circular magnetic core with a polyphase winding thereon in series with the circuit.



903,875.—MODIFIED SUSPENSION-TYPE INSULATOR.

903,972. PIGTAIL BRUSH. Lee C. Hawley, Cleveland, Ohio, assignor to National Carbon Company, Cleveland, Ohio. Filed February 13, 1908. A brush has a transverse hole with a pigtail made of fine wire braided into tubular form, which is distended into intimate contact with its walls.

903,987. CONTACT DEVICE. Frank B. Klopf, New York, N. Y., assignor to Universal Safety Car Controller Company. Filed December 13, 1906. Comprises a casing and a contact member pivotally mounted on a carrier and projecting through an opening in the casing.



904,072.—NITROUS OXIDE PREPARATION.

904,001. ELECTRIC SECONDARY CLOCK. Horace B. McCabe, Chicago, Ill., assignor of one-half to Joseph E. Cochran, Chicago, Ill. Filed November 12, 1906. There are means for transmitting the movement of the magnet armature to a shaft.

904,011. OUTLET BOX. Erwin L. Pierce, Everett, Mass., assignor to Charles S. Knowles, New Bedford, Mass. Filed August 31, 1907. The box has an opening in its wall, an outer stopper partly punched from the body of the box and an inner stopper partly punched from the outer stopper.

904,018. ELECTRICAL SIGNALING SYSTEM. Joseph P. Sauer, Wheaton, Ill. Filed April 10, 1906. In combination with a section of track is a source of current, a controlling relay and an electrically actuated annunciator controlled by the relay.

904,031. TRAPPINGS FOR HORSES. Chelsea L. Warner, Cincinnati, Ohio. Filed June 2, 1906. An incandescent lamp is mounted on a strap. The wires lie between the top and bottom layers thereof.

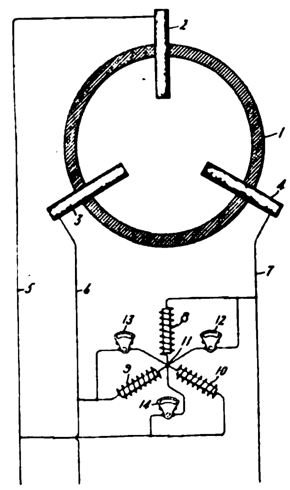
904,042. SWITCH-OPERATING MECHANISM. Robert Brown, Westminster, London, England. Filed July 25, 1906. In a sectional-conduit railway system each car carries a switch-actuating device projecting into the conduit.

904,069. INSULATOR. Willard H. Kempton, Trimble, Ohio. Filed December 16, 1907. The strain insulator has a cylindrical shell formed of longitudinal sections and vitrified insulating blocks extending through the ends of the shell.

904,070. PROCESS FOR EFFECTING CHEMICAL ACTION IN GASES. Dimmitt R. Lovejoy, Niagara Falls, N. Y., assignor to Walter E. F. Bradley, trustee, New York, N. Y. Filed February 18, 1903. The process consists in subjecting the mixture of the gases to the influence of a radio-active body and to the action of an electric arc.

904,071. APPARATUS FOR CHEMICALLY COMBINING GASES. Dimmitt R. Lovejoy, Niagara Falls, N. Y., assignor to Walter E. F. Bradley, trustee, New York, N. Y. Filed February 18, 1903. A combining chamber has electrodes mounted within, means for controlling arcs, means for conducting gases into the influence of the arcs and means for either liquefying or solidifying the gases.

904,072. PROCESS OF CHEMICALLY COMBINING GASES. Dimmitt R. Lovejoy, Niagara Falls, N. Y., assignor to Walter E. F. Bradley, trustee, New York, N. Y. Filed February 18, 1903. A process of promoting the chemical combination of nitrogen and oxygen consists in subjecting the gases to an electric arc and simultaneously refrigerating the nitrous oxides formed.



904,194.—POLYPHASE FURNACE REGULATION.

904,073. APPARATUS FOR EFFECTING CHEMICAL ACTION IN GASES. Dimmitt R. Lovejoy, Niagara Falls, N. Y., assignor to Walter E. F. Bradley, trustee, New York, N. Y. Filed February 18, 1903. Renewed March 23, 1908. This is a modification of numbers 904,070 and 904,072.

904,097. CONNECTOR. Mertie O. Spring, Schenectady, N. Y., assignor to General Electric Company. Filed November 12, 1904. Two terminals are each provided with a clamping face at one end that can be screwed together, the rear ends being protected by an insulating casing.

904,105. TELEPHONE-EXCHANGE SYSTEM AND APPARATUS. Dudley B. Wick, Jr., Cleveland, Ohio, assignor to the North Electric Company, Cleveland, Ohio. Filed September 8, 1904. In combination with the cord circuit is a control-relay having opposite windings governing supervisory signals partially.

904,115. STORAGE BATTERY. Rufus N. Chamberlain, Depew, N. Y., assignor to Gould Storage Battery Company, Depew, N. Y. Filed February 6, 1906. Relates to the construction of the top of a battery jar or tank and a cover therefor.

904,116. RAILWAY BLOCK-SIGNALING SYSTEM. Harry M. Coulter, Chicago, Ill., assignor of one-half to Alfred Stromberg, Chicago, Ill. Filed April 8, 1907. Each block contains a controlling relay in a normally closed track circuit.

904,128. ELECTRIC CLOCK. Robert D. Hickok, Atlanta, Ga. Filed March 27, 1908. In combination with the pendulum rod is an armature frame.

904,139. PROCESS OF MAKING FILAMENTS FOR LIGHTING AND HEATING. Georges Michaud and Eugene Delasson, Paris, France. Filed August 18, 1905. Consists in mixing together alumina and oxides of thorium, cerium and chromium, reducing this to the form of a fine powder, fusing the mixture in a fine stream, and finally forming the fused mas into a filament.

904,157. COMBINED TELEGRAPHIC TRANSMITTER AND TYPEWRITING MACHINE. Augustus G. Snyder, Ilion, N. Y., assignor to Wyckoff, Seamans & Benedict, Ilion, N. Y. Filed April 8, 1904. Includes a series of keys and printing means operated thereby and a series of reciprocatory circuit controllers for transmitting telegraphic signals.

904,185. ARC LAMP. Edward O. Dworak, Chicago, Ill. Filed July 16, 1906. In a regulator for arc lamps there is a pair of supporting tubes with sleeves adapted to slide therein for supporting the carbon rods.

904,194. REGULATION OF POLYPHASE FURNACES. Richard Fleming, Lynn, Mass., assignor to General Electric Company. Filed February 13, 1908. A substantially constant-voltage polyphase source has reactances connected at one end to electrodes and at the other end to a common neutral point and voltmeters connected in parallel with the reactances.

904,196. ELECTRIC IGNITER FOR EXPLOSIVE ENGINES. George A. Goodson, Minneapolis, Minn. Filed February 8, 1902. A magneto generator supplies current for the spark intermittently.

904,203. FUEL HEATER FOR EXPLOSIVE ENGINES. Harry Hertzberg, New York, and Abbot A. Low, Horseshoe, N. Y.; said Hertzberg assignor to said Low. Filed October 10, 1907. There are means for supplying current to a heating member composed of resistance material.

904,222. OSCILLATION-DETECTING MEANS FOR RECEIVING INTELLIGENCE COMMUNICATED BY ELECTRIC WAVES. Greenleaf W. Pickard, Amesbury, Mass. Filed March 11, 1907. Two massive electrical conductors having high thermoelectric power are pressed in contact with each other.

904,248. MEANS FOR REMOVING STATIC ELECTRICITY. William H. Chapman, Portland, Me. Filed February 18, 1907. A strip of non-conducting material has enclosed therein a conductor with portions extending to and terminating flush with the surface of the strip and presenting small points to the air.

904,263. PROCESS OF OBTAINING METALS FROM THEIR ORES. Karl Kaiser, Berlin, Germany. Filed June 22, 1906. Consists of heating raw materials in an electric furnace, then forcing air and finally a gaseous reducing agent into contact with the molten mass until the metals are reduced.

904,280. MAGNETIC SEPARATOR. Marcus Ruthenburg, Lockport, N. Y. Filed June 22, 1907. A vertical rotary shaft carries a magnet comprising opposed annular polar projections.

904,320. SWITCHBOX. Edward J. Dustman, New York, N. Y. Filed April 27, 1907. A wall switchbox has two separable sections arranged so as to allow inclination of one relatively to the other.

904,359. TROLLEY HARP. Joseph Pensis, Speers, Pa. Filed January 31, 1908. One prong of the harp is prolonged beyond the other and extends outwardly to form an arm supporting a trolley-retaining bar.

904,367. RELAY FOR TELEGRAPHS. James Scotland, Hearts Content, Newfoundland. Filed July 10, 1907. The relay has a cylindrical armor for the electromagnet.

904,369. INSULATING BUSHING. Louis Steinberger, New York, N. Y. Filed July 12, 1907. Comprises a number of cylinders, one being provided with a projecting portion which serves as a shed.

904,370. DISK-STRAIN INSULATOR. Louis Steinberger, New York, N. Y. Filed January 20, 1908. A pair of suspension members are separated and partially enveloped by a mass of insulating material provided with flanges extending in opposite directions.

904,415. WATCHMAN'S TIME REGISTER. George W. Ellis, Germantown, Pa. Filed July 3, 1908. An armature in connection with a magnet engages an arm to operate a shutter.

904,420. APPARATUS FOR COOLING ROOMS. Pauline Grayson, New York, N. Y. Filed May 29, 1907. An electric motor operates a circulating fan.

904,425. MEANS FOR AUTOMATICALLY OPERATING GAS OR OTHER VALVES OR ELECTRIC SWITCHES AT PREDETERMINED TIMES. Arnold Hare, Auckland, New Zealand. Filed July 10, 1907. A clock-controlled and spring-actuated time switch.

904,441. COMBINED TELEPHONE-EXCHANGE AND ALARM SYSTEM. John M. Latimer, Philadelphia, Pa., assignor to Consolidated Fire Alarm Company. Filed April 21, 1900. There is a local alarm-transmitting apparatus for establishing grounded connections with the telephone circuit.

904,458. JUNCTION BOX. John N. Scism, Syracuse, N. Y. Filed January 13, 1908. Comprises a shell having a closed bottom and an open top with a plate extending across the opening and removably secured to the shell.

904,462. INTERMITTENTLY DRIVEN MECHANISM ADAPTED FOR CONSTANT DRIVING. Horace H. Taylor, San Jose, Cal., assignor of one-half to Frank J. Mayhew, San Francisco, Cal. Filed July 13, 1907. An electrical circuit-controlling mechanism comprises a chamber and piston, a number of contacts and means actuated by the piston for connecting the contacts.

904,463. CLUTCH. Horace H. Taylor, San Jose, Cal., assignor of one-half to Frank J. Mayhew, San Francisco, Cal. Filed July 13, 1907. Two electromagnets are arranged to oscillate a clutch-moving lever into and out of action.

904,467. ELECTRIC-LIGHTING DEVICE. Clarence Wheeler, Rochester, N. Y., assignor to Metal Specialties Manufacturing Company, Chicago, Ill. Filed September 17, 1907. A hollow handpiece is provided with a metallic socket and a terminal.

904,476. ATTACHMENT FOR INCANDESCENT-LAMP SOCKETS. Henry H. Ham, Shrewsbury, Mass., assignor of one-half to Edwin W. Ham, Worcester, Mass. Filed May 12, 1906. Renewed March 19, 1908. A lamp socket is provided with a switch-operating chain and a movable arm keeping the chain out of contact with the lamp shade.

904,482. INCANDESCENT LAMP. John W. Howell, Newark, N. J., assignor to General Electric Company. Original application filed November 17, 1906. Divided and this application filed October 23, 1907. This is a modification of No. 903,860.

904,486. PROTECTIVE APPARATUS FOR SWITCHBOARDS AND THE LIKE. William Kaisling, Chicago, Ill., assignor to Frank B. Cook, Chicago, Ill. Filed October 5, 1903. A heat coil arrester for a telephone switchboard.

904,491. TROLLEY HEAD AND HARP. Charles E. Marks, Virginia Beach, Va., assignor of one-fourth to Algar M. Wheeler, Norfolk, Va. Filed September 6, 1907. The harp has a pair of guiding wheels at each side of the upper portion of the trolley wheel.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired November 24, 1908:

463,615. ELECTRIC CONTROLLER FOR ELEVATORS. W. Baxter, Jr., Baltimore, Md.

463,639. ELECTRIC MOTOR MECHANISM. S. E. Mower, New Haven, Conn.

463,671. ARMATURE CORE FOR DYNAMO-ELECTRIC MACHINE. E. Thomson, Lynn, Mass.

463,693. ELECTRIC MOTOR AND GENERATOR. I. E. Storey, Boulder, Colo.

463,704. ELECTRIC MOTOR AND DYNAMO. A. L. Parcelle, Boston, Mass.

463,711. ELECTRIC METER. A. Rechenzaun, London, England.

463,715. CONDUCTOR AND GUIDE FOR ELECTRIC-RAILWAY TROLLEYS. J. I. Conklin, Brooklyn, N. Y.

463,720. ELECTRIC ARC LAMP. W. S. Hays, Troy, Ohio.

463,761. SECTION INSULATOR AND LIGHTNING ARRESTER FOR ELECTRIC RAILROADS. E. Thomson, Swampscott, Mass.

463,762. ELECTRIC ARC INTERRUPTER. E. Thomson, Swampscott, Mass.

463,765. TROLLEY FOR ELECTRIC RAILWAYS. G. H. Alton, Lynn, Mass.

463,766. SWITCH FOR ELECTRIC RAILWAYS. F. O. Blackwell, Boston, Mass.

463,770. ELECTRIC CUT-OUT. E. W. Rice, Jr., Lynn, Mass.

463,793. SYSTEM OF ELECTRIC LIGHTING. E. J. Hodgson and J. W. Stearns, Jr., Denver, Colo.

463,802. ELECTRICAL TRANSMISSION OF POWER. H. W. Leonard, New York, N. Y.

463,808. ELECTRIC SUBWAY SWITCH. L. A. Fehr, New York, N. Y.

463,852. SYNCHRONOUS TELEGRAPH. C. S. Bradley, Yonkers, N. Y.

463,867. AUTOMATIC SAFETY CUT-OUT FOR ELECTRICAL CONDUCTORS. R. A. Morgan, Jr., Boston, and G. C. Bosson, Jr., Lawrence, Mass.

463,879. SEPARATOR FOR THE PLATES OF SECONDARY BATTERIES. C. F. Waldron, Boston, Mass.

463,955. ELECTRIC WIRE INSULATOR. H. F. Newell, Manchester, Va.

ELECTRICAL REVIEW
AND
WESTERN ELECTRICIAN

VOL. LIII, No. 23. | CHICAGO, SATURDAY, DECEMBER 5, 1908. | ISSUED WEEKLY

BY THE
ELECTRICAL REVIEW PUBLISHING COMPANY.
CHARLES W. PRICE, President.
STEPHEN H. GODDARD, Vice-President. H. S. TUTHILL, Secretary.
PHILIP S. DODD, Manager. C. W. FORBRICH, Assistant Treasurer.

CONTENTS.

CABLE-RATE REFORM IN ENGLAND.

Not in a long time have the people of Great Britain been so stirred as they now are over the agitation which is being led by Mr. J. Henniker Heaton's call for a universal two-cent charge for international cable messages. This redoubtable member of Parliament has arrayed himself against the great commercial interests operating the international cables connecting Great Britain and America, and, with characteristic zeal and pertinacity, has brought to bear the heavy ordnance of his logic and some startling figures to back up his contentions as the champion of the non-users of the cable systems.

Mr. Heaton claims that the cable systems are in the hands of monopolists; that the cables are arbitrarily left in idleness for a third of the time, so that exorbitant rates may be charged, and that the service as at present conducted is available largely to those business interests which must make use of it whatever the rate. In his analysis of the use of the cable he discovers that ninety-seven per cent of all the messages are from business houses, and that public participation in cable service is very small indeed. The capitalization placed upon existing systems, he says, is out of all proportion to their worth, and he makes the additional statement that if all the cable systems at present in use were wiped out it would be possible to reconstruct the whole system between the British Isles and America for $30,000,000.

It is a fact that the public will give hearty support to anything which appears to cheapen the price of a service, the question as to whether the cheapened service can or will be used not entering very largely into the decision. It is not only the general public, however, which is interested with Mr. Heaton in piling up a great wave of protest, for he has the support and influence of prominent men and women, and it may be noted also that a number of the influential papers of both countries are giving him more than ordinary encouragement.

When the proposition was at first brought up, those in charge of the destinies of the cable companies were inclined to pooh-pooh the idea, regarding it as highly chimerical. This can hardly be considered a safe procedure, however, for the people have realized that public clamor sometimes brings direct results. If a universal penny-a-word cable rate were established, with its burden of deficit—which, under present conditions, appears inevitable—thrown upon the Government, the cable companies would appear to be serving the people at large with less generosity than they are even now credited; for if the rate be exorbitant now, it is borne by those who use the service, while any burden of deficit carried by the Government would become a tax on the whole people. It does not appear reasonable either that a reduction to a penny a word would result in nearly so large a proportionate increase of common use as the projectors of this scheme have suggested, and the probability is that with a lower rate there would be a still greater monopoly of cable service on the part of business interests. It is all very well to say that commerce is throttled, but it takes more than the control executed by a few companies over sixteen cables to do much throttling.

The probability exists, of course, that with proper incentive and imperative necessity, the operation of the cable systems can be cheapened, and that in consequence of an increased demand, more continuous use can be made of the cables already in service. The prospect of adequate return upon a large investment may also influence the laying down of new lines of communication. Nothing is being done so well that it can not be improved upon. The only thing necessary is the expedient, and a decent and orderly procedure to secure its consummation. The cable industry has grown to vast proportions, and has required large expenditures of money, and those who originally invested took long chances of there ever being an adequate return. If there has been a monopoly, and if the rates have been higher than a reasonable return would seem to require in this direction, it appears reasonable to assume that a large tribute should be paid for the facility which has been developed. It is, of course, unreasonable to expect that the present conditions can continue indefinitely, for some time there must be an end to the exacting of unreasonable tariffs. If that point has now been reached, proper investigation will discover it, but the companies should, and, in all likelihood, will, resist any attempt by methods, confiscatory or otherwise, looking to a cheapening of service and an unprofitable end, whether the burden be borne by the Government or by the cable companies.

The proposition of government ownership of the international cable systems seems stupendous when the capitalization of the companies is reviewed. Between Great Britain, Germany, France and America there are sixteen working cables operated by six companies. The Western Union system is made up of the American Telegraph and Cable Company, with two cables; the Anglo-American Cable Company, with four cables, and the Direct United States Cable Company, with one cable. The Commercial Cable Company operates or controls seven cable lines—four of its own, two of the German Cable Company, and one land line for feeding the Commercial system. The other large transatlantic system is that of the French Cable Company, operating two cables—making up the quota of sixteen. The Mackay Companies, operating the Commercial Cable Company, has an authorized capital of $100,000,000; the American Telegraph and Cable Company, $14,000,000 outstanding; the Anglo-American Telegraph Company, a capitalization of $35,000,000; and the Direct United States Cable Company, a capitalization of $11,256,000. Adding in the capitalization of the Central & South American Telegraph Company, $8,000,000; the Mexican Telegraph Company, $3,000,000, and that of fifteen smaller companies operating international cables, the stock of which is largely held in England, amounting to $10,265,000, we have a total capitalization of $187,592,000. It is hard to arrive at a definite estimate of either the capitalization or value directly applicable to cable resources, because the capitalization of several of these companies is devoted also to land lines, real estate and other tangible assets. But the figures given are a close approximation of the magnitude of the problem involved.

The matter has not attracted the attention in this country that has been given to it abroad. When agitation such as this, however, gets away from reasonable restraint there is a possibility of unreason running rampant. The subject should be viewed in the broadest possible light, and intelligent publicity given to every phase, so that there may be no mistake made in arriving at a sensible conclusion.

THE NEW YORK STATE PUBLIC SERVICE COMMISSION REPORT.

The second volume of the report of the Public Service Commission for the First District of the State of New York on the work carried out during the first six months of its existence—the period ending December 31, 1907—gives some interesting information concerning the public-utility corporations included in the district under the commission's regulation. One of the points brought forward is that extension and improvement of transit facilities brings increased travel, apart from the natural increase in population. This means that as lines are carried into remote communities, and tributaries to main arteries penetrate into easy riding distances, the public automatically gets the riding habit. In Greater New York the statistics show that there was a daily average increase of 341,000 passengers in 1907, the whole year showing an increase of 124,505,734, including regular fare and transfer rides.

Four-fifths of the traffic conducted by the street railways of New York state is handled in the greater city. The number of passengers is almost equal to the entire number carried by the tramway systems of England and Wales.

One of the curious points noted is that on over 103 miles of electrically-operated surface lines and forty-four miles of horse-car lines, the average speed is seven-and-one-half miles an hour. This would appear to be pretty slow traveling, but it should be remembered that a large part of the traffic is in localities where passengers are picked up and dropped at every street corner for possibly four-tenths of the distance traveled, and that the stoppages are included in the over-all speed. The forty-four miles of horse-car lines is divided into several cross-town lines serving the various ferry terminal points, where for the amount of traffic and the short distance of the run it is not considered commercially practicable to install an expensive conduit system, such as is called for by the restrictive regulations in force in New York city against overhead construction.

Probably no city has suffered so much from transfer abuse as Greater New York, and this matter has been a bone of contention between the passengers and the railway companies for the last few years. When the proposition of universal transfers was first inaugurated there appeared to be a decided increase in the profitable traffic attracted to the lines. Very soon, however, the public learned to make the greatest possible use of the transfer system, and it is estimated that the abuse of the transfer system has made deep inroads into the revenues of the railway companies. A careful study of these conditions on the part of the railway operators has apparently revealed some illogical concessions in the establishment of promiscuous transfer points, and an effort is now being made to eliminate these as far as possible. The cutting off of such privileges on several lines in New York city has recently led to considerable antagonism on the part of the riding public, and several hearings have been held before the Public Service Commission, with, in one case, a decision against the company and an order to re-establish the transfer privilege at the disputed point, and the consequent refusal on the part of the company to obey the mandate of the commission. This is an interesting situation, which will only be relieved by a painstaking process of law.

The report states that there are fifty-one transfer passengers to each 100 fare passengers in New York city. Notwithstanding the increase in transfers, however, the experts on the commission have figured that this has not been at the expense of the railroads. They estimate that this growth has not been provided for in the establishment of higher car-mile figures, but has increased the passenger miles, which has resulted in the uncomfortable overcrowding of the cars in use. This has been deduced from the fact that while the receipts per passenger declined from 4.14 cents to 4.04 cents, the number of car-miles increased only 3.8 per cent; while the number of fare passengers increased 5.2 per cent, and the number of all passengers 7.9 per cent. The result is an apparent increase in the average passenger car earnings from 25.58 cents per car-mile in 1906 to 25.89 cents in 1907.

TUNGSTEN LAMPS VERSUS ACETYLENE PLANTS.

Acetylene-gas apparatus comes into direct competition with electric equipment where small lighting plants are wanted, due to the low first cost of the former.

While acetylene-gas plants are more commonly confined to single buildings or private grounds, they are also designed for general public supply in an increasing number of small villages, where there is no other gas or electric service. An illustration of this latter fact may be noted in a certain state where fourteen acetylene-gas plants are now engaged in general public supply, though there was not a single public plant of this sort in the state seven years ago. Acetylene plants for either public or private use compete much more directly with electric apparatus than with ordinary gas equipments, because the capacities of these plants are so small that coal or water-gas appliances are not suited to the purpose.

At the start, the use of tungsten lamps reduces the necessary capacity of boilers, engines, dynamos and wiring circuits by sixty per cent, if the comparison is made with 3.1-watt carbon-filament lamps, on a candlepower basis. In other words, an electric plant for 1,000 candlepower in incandescent lamps, corresponding to 500 lamps of sixteen candlepower, requires only forty per cent of the capacity in generating apparatus and conductors for tungsten as for carbon lamps.

Even where only one lamp per lighting point is wanted, so that the full benefit of the higher efficiency of the tungsten filament can not be obtained, the twenty-five-watt tungsten lamp enables the capacity of the generating plant and line to be reduced fifty per cent below the requirements for fifty-watt carbon lamps.

Comparatively little competition exists between electric and acetylene-gas plants engaged in public supply, but the conditions of such competition may be noted. Probably the most common price for acetylene gas from public plants is $15 per one thousand cubic feet, though the price ranges from about $12 to $20, and it requires the best grades of open burners to yield eighteen candlepower on one-half cubic foot per hour, or forty candlepower on one cubic foot. At $15 per one thousand feet, the cost of acetylene gas is thus 1.5 cents per hour at the forty-candlepower burner, and 0.75 cent per hour at the eighteen-candle burner.

Though a forty-candle tungsten lamp is not a standard size for interior use, it will do as well for comparison as any other, and would consume fifty watts. At ten cents per kilowatt-hour, the energy for this fifty-watt lamp costs 0.5 cent per hour, and the energy for a twenty-candle, twenty-five-watt tungsten lamp costs 0.25 cent per hour.

For the hourly cost of the tungsten lamp alone, a list price of $1.50 and an average life of 1,000 hours may safely be taken, as the discounts will fully offset any probable shortage of this average life.

This basis gives 0.15 cent as the cost of the tungsten lamp itself per hour of use, and this sum, added to the above figures for the energy consumed in each lamp, amounts to 0.65 cent for the forty-candlepower size, and 0.4 cent for the twenty-candlepower, per hour, as the total cost.

With acetylene gas costing 1.5 cents per hour at the forty-candlepower burner, and 0.75 cent per hour at the eighteen-candlepower, or about twice the cost of equal illumination with tungsten lamps, the failure of acetylene plants to compete successfully with electric in public supply is very plain.

As to isolated plants, the argument for acetylene apparatus is low cost of light compared with the price of electric service. Calcium carbide, from which acetylene gas is made, costs $70 per short ton, or 3.5 cents per pound, in the cheapest form made for use in acetylene-gas generators, and five cubic feet of the gas per pound of carbide is a very favorable yield. It follows that 0.2 cent per cubic foot is about the minimum cost of acetylene gas, for carbide alone, and this makes no provision for interest on the first cost of the generating plant, or for labor, repairs and depreciation.

The bare cost of carbide is thus 0.7 cent per hour for the forty-candlepower burner consuming one cubic foot, and 0.35 cent per hour for the eighteen-candle-burner using one-half cubic foot.

Compared with the above total costs of 0.65 cent and 0.4 cent per hour for forty and twenty-candlepower tungsten lamps, respectively, when operated with current sold at the rate of ten cents per kilowatt-hour, and lamp renewals extra, the cost of the carbide alone is 0.05 cent more for the one-foot burner, and only 0.05 cent less for the one-half-foot burner, per hour of lighting.

INDEPENDENT TELEPHONE CONVENTION.

TWELFTH ANNUAL GATHERING, AUDITORIUM, CHICAGO, DECEMBER 1, 2 AND 3.

The twelfth annual convention of the International Independent Telephone Association was held at the Auditorium Hotel, Chicago, during the last week. A total attendance of several hundred representatives of independent companies of the United States and Canada was predicted, and the roster of the registration committee early confirmed this estimate of the complete attendance, representing "4,000,000 telephones and 17,000,000 exclusive users."

The first convention session proper was called to order in the banquet hall of the Auditorium Hotel on Tuesday morning by P. C. Holdoegel, of Rockwell City, Iowa, the acting president. Following the invocation by the Reverend Frank G. Smith, of Chicago, the welcome of the city of Chicago was extended to the Independent telephone men by George M. Bagby, assistant corporation counsel of the city administration, acting for Mayor Fred A. Busse, who, though scheduled for an address, was unable to be present. The response was tendered by R. D. Critchfield, president of the Wisconsin Telephone Association. His address was quite impromptu, taking the place of Dwight E. Sapp, of Mt. Vernon, Ohio, who was unable to fill the place accorded him on the programme, but in convincing and unmistakable terms Mr. Critchfield urged upon the city of Chicago consideration of telephone connection with the large proportion of Independent telephone subscribers in the state and vicinity. The report of the secretary, Joseph B. Ware, of Grand Rapids, Mich., was lengthy and detailed, and gave a comprehensive history of the Independent movement during the past twelve months.

The afternoon session was given over to a technical and practical conference, at which the papers read partook of an operating and traffic character contrasted with the business and financial aspects of the morning's meeting. The technical meetings were in charge of Gansey R. Johnson, of Columbus, Ohio.

The first paper presented was that of Roy Owens, of Columbus, O., on "The Telephone Engineer in His Relation to the Telephone Business."

"The three divisions of telephone engineering," said Mr. Owens, "are, planning, constructing and maintaining. It is not uncommon to hear engineers say that they wish to devote themselves to construction and not to maintenance. Some of these are apparently indifferent to the planning. In these respects they are not giving themselves credit for being complete engineers. The planning is the really vital part of a telephone engineer's duty. One reason why more plants have not shown the result of poor design is that the demand for telephone service in years past has tended to outrun the capacity of the plants, so that even a poorly laid out cable system has found practically all of its cable pairs called for. As time goes by, however, and subscribers are more difficult to procure, the need of more care in the laying out of the plant will become manifest.

"The cable distribution is the most costly part of an engineer's work. A local telephone company may stand or fall with its degree of success in getting cable into those parts of its exchange district where cable will be in demand. The multiple-cable distribution methods somewhat widen the narrower limits within which cable distribution is flexible. The subway and pole lines must be so far complete that there is little demand for their flexibility. The switchboard terminals and the subscribers' lines and instruments have a large degree of flexibility.

"Care should be taken to have the most economical balance between the outside capacity and the switchboard capacity, which means that the former should be somewhat more than the latter."

J. H. Ainsworth, general manager Home Telephone Company, Dayton, Ohio, discussed "Some Economies in Handling Maintenance Men." His company has introduced a feature of requiring the repair men to report upon a printed slip whether repairs made are of a permanent or temporary character, as it is not always possible for a single workman to effect repairs of a permanent nature. If the latter is the case, the repairman is instructed to report so, but after the trouble is permanently remedied each man is held to strict account for recurring troubles in his district.

"Maintenance Economics" was the title of a brief paper read by G. E. Bickley, of Waterloo, Iowa. Any reasonable expenditure made to conserve the operation of the equipment, material or apparatus of a telephone system, is an economy, he said. Mr. Bickley also indicated a plan of postcard report of line inspections made in the course of other business, and advised, as well, the special inspection of the right-of-way, locating by chart possible prospective troubles.

The paper of J. P. Boylan, of the Home Telephone Company, Detroit, Mich., on "Handling Trouble," was read by B. H. Brooks, chief engineer of the same company. Careful tests by operators were advised to anticipate the discovery of trouble by the subscriber, and the author described a card system of filing this class of records. In explaining the difficulty often experienced in attempting to ring out on a short-circuited line, the writer described a form of relay designed to be placed in the generator lead to the position. This relay has an inductive winding shunted by pure resistance. The latter path may be opened by the armature picking up when an undue current traverses the relay winding. Thus normally the combined paths represent low impedance until the heavy short-circuit current actuates the armature, leaving only the highly-inductive winding in circuit, and at the same time lighting a pilot lamp in view of the operator.

The technical session was continued in the evening, but on account of the small attendance the papers presented were abstracted by the authors.

Frank F. Fowle, consulting electrical engineer, read an interesting and classical paper on "The Economical Development of Toll Territory."

"The purpose of this paper, as the title suggests, is a consideration of the principal factors in building up and developing a toll plant on a dividend-paying basis. There are naturally two divisions of the subject, namely, the projection of an entirely new plant in undeveloped territory, and the development of a plant already in existence; but the latter division of the subject grows out of the first, and undeveloped territory will be assumed as the starting point. Were there no previous experience in the toll business to furnish guidance in laying out a new plant in undeveloped territory, it would be necessary to proceed with the utmost caution; in fact, the whole development would necessarily be experimental and would involve a large financial risk.

"It is found that the public demand for toll service occurs in such ways that certain laws may be formulated which will express mathematically or graphically the volume of message traffic which will occur on the average under any given or known set of conditions. The design of a toll system divides itself naturally therefore into two parts, first the predetermination of the traffic, and second the layout of a plant which will provide the necessary facilities in the most economical manner; under the system of rates charged or to be charged it becomes apparent at once what portions of the proposed plant will be profitable at the outset, or, if the rates are not settled in advance, an estimate may be made of the plant charges and the operating costs to handle the traffic, as predetermined, upon which may be based a system of rates which will insure dividends from the outset."

Mr. Fowle had made a study of the traffic between different cities and towns, taking into account their population and the distance between them, under a fixed-rate schedule. It was found that the traffic volume in total messages per month in both directions between any pair of zones could be fairly represented by the formula:

$$T = .00022 \frac{P_1 P_2}{D^2}$$

where T = the total messages per month in both directions.
P_1 = population of either zone.
P_2 = population of the other zone.
D = distance between the zone centers, in miles.

The formula as written may be regarded as possessing sufficient accuracy for a development study. The range of distances and population in the instances upon which the calculations for the constant were based, was very large; no account was taken of the telephone development in the zones used for calculation, but it varied from something like one per cent up to eleven or twelve per cent, with an average of six to seven per cent.

Other formulæ were indicated for the determination of toll rates, revenue per message, etc., and a quantity of valuable cost and physical data was given. Mr. Fowle exhibited a number of interesting long-distance telephone plant load curves showing the distribution of calls throughout the week, the effect of a night half-rate on the service for different days, the relation between speed of service and circuit loads, etc.

Following his paper, Mr. Fowle was called upon to explain the action of loading-coils on a telephone line. In complying, he took occasion to discount the general fallacy that these coils introduce a condition of resonance into the circuit. On open construction the loading-coils are usually placed at the transposition points, about eight miles apart. On cables the distance varies from three-quarters of a mile to one-and-one-half miles. In some cases their interposition has the effect of increasing the transmission four or five fold, but this ratio of improvement decreases for the larger conductors.

George K. Gann, Lincoln Neb., in a paper on "Handling Long Distance Traffic," described the two recording methods most generally used and applicable to either large or small offices. These might be termed: (a) The direct ring-down method; (b) the order wire method.

"The direct ring-down method requires trunks from the 'A' boards in the local offices, terminating at the recording board in signals and jacks. These should be multipled in each position or section in offices where there are two or more. The method of operation is as follows:

"1. The subscriber removes the receiver from the hook, lighting the signal on the 'A' or local board.

"2. The 'A' operator takes one of the cords of an idle pair, plugs into the answering jack of the subscriber's line, and answers 'number.'

"3. The subscriber asks for 'Long Distance.'

"4. The 'A' operator takes the other cord of the pair, tests, and plugs into a jack of an idle trunk to the recording board and rings, thus lighting a signal on the same trunk at the recording board.

"5. The recording operator takes one of the cords of an idle pair, plugs into the jack of the trunk on which the signal has been received and answers, 'Long Distance.' She then secures and records the subscriber's call on a ticket and has it sent or carried to the proper line operator.

"The order wire recording method differs from the first in that the trunks to the recording board appear only in the 'A' and 'B' boards of the principal local exchange. Other local exchanges must secure connection with the recording operator by cutting in on the regular order wire to the principal office 'B' board, and asking for 'Long Distance.' The 'B' operator makes a trunk assignment in the usual way, establishing connection with a trunk to the recording board."

The technical and business sessions were continued during Wednesday and Thursday. On Wednesday evening the annual association banquet was held.

The Independent telephone convention was marked by an unusually fine array of manufacturers' exhibits on several floors of the Auditorium Hotel. Most of these occupied suites on the banquet-room floor, convenient to the convention hall. The exhibits included manual and automatic telephones and switchboards, wire, construction material, protective devices, batteries, conduit, tools and motorcycles.

The following exhibitors occupied hotel rooms or suites with complete expositions of their products:—

American Electric Telephone Company; Automatic Electric Company, Chicago; Century Telephone Construction Company, Buffalo, N. Y.; Chicago Telephone Supply Company, Elkhart, Ind.; Cracraft-Leich Electric Company, Genoa, Ill.; H. E. Cobb, Chicago; Frank B. Cook, Chicago; Corwin Telephone Manufacturing Company, Chicago; W. H. Couch, Boston, Mass.; Dean Electric Company, Elyria, Ohio; Duplex Metals Company, New York city; Electric Appliance Company, Chicago; Excelsior Supply Company, Chicago; Fibre Conduit Company, New York city; Fox & Borden Manufacturing Company, New York city; H. S. Green Battery Company; Holtzer-Cabot Electric Company, Brookline, Mass.; Illinois Electric Company, Chicago; Indiana Steel and Wire Company, Muncie, Ind.; Manhattan Electrical Supply Company, Chicago; Miller Anchor Company, Norfolk, Ohio; Monarch Telephone Manufacturing Company, Chicago; National Carbon Company, Cleveland, Ohio; North Electric Company, Cleveland, Ohio; Ohio Brass Company, Mansfield, Ohio; F. W. Pardee, Chicago; Pierce Specialty Company, Elkhart, Ind.; Homer Roberts Telephone Company, Chicago; St. Louis Malleable Casting Company, St. Louis, Mo.; Sterling Electric Company, Lafayette, Ind.; Stromberg-Carlson Manufacturing Company, Rochester, N. Y.; Swedish-American Company, Chicago; *Telephony*, Chicago; Vote-Berger Company, La Crosse, Wis.; Warner Electric Company, Muncie, Ind.; Westinghouse Machine Company, East Pittsburg, Pa.

Plan New Telegraph Company.

The revived plan of Chicago Board of Trade operators to establish an independent telegraph company and use independent telephone wires between Chicago, St. Louis and Kansas City, which was begun a year ago, is now again projected in the name of the People's Mutual Telegraph Company.

The promoter of the enterprise is W. S. Jackson, ex-president of the Chicago Board of Trade. An ordinance is asked of the City Council permitting the stringing of wires under the Metropolitan Elevated structure.

Electrification of Steam Railroad Terminals in Chicago.

The Illinois Central Railroad is not the only one making an investigation of the feasibility of electrifying its Chicago terminals. Since the agitation for the electrification of this railroad began a large number of other railroads entering the city have been quietly making more or less exhaustive studies of the problems as related to their lines.

The suburban residents along the Chicago, Rock Island & Pacific and the Chicago, Burlington & Quincy railroads are agitating electric service on these roads. The managements of these lines and of some others realize that it is a problem that will have to be faced in the near future. Since not only the patrons of the roads and their adjacent property owners, but the city authorities as well, have been determined to have the smoke nuisance produced by their locomotives abated, the success and economy of the electrification projects that have been carried out in the East have convinced the managements that electrification has advantages not only in satisfying the public clamor but in providing an efficient tractive power.

Aside from the Illinois Central Road these investigations have as yet been carried out very quietly. The manager of one of the western roads, which owns large terminals in the city, stated recently: "There is not the slightest doubt that the city will eventually pass an ordinance acquiring electrification of the railroad terminals. Such a measure could not with equity require electrification of freight terminals at this time, but would probably deal first with the passenger traffic. There are some roads which are in a fairly good position to electrify their passenger terminals when the proper time comes—the time when they know what the best system is." The purpose of some of these investigations is to find out which system, single-phase or third-rail, is best suited for their purpose. It is generally believed that the officials of at least one system entering Chicago were more in favor of electrifying its lines than the officials of the Illinois Central Railroad have been until recently.

The city authorities in considering this subject have referred to the corporation counsel for an opinion on the power of the city to produce the changes desired. The opinion has just been prepared and states that the city probably has no direct power to compel electrification of the steam railroads. However, it does have power to prohibit the use of steam as a motive power if it can be shown that its use is attendant with emission of smoke, soot, cinders or otherwise injuriously affects the public health, comfort or property so as to amount to a public nuisance.

At a conference held on November 30 between the city authorities and officials of the Illinois Central Railroad the progress of the work on the latter road was reported. Some fifty plats have been prepared of the trackage so as to enable the electrification project to be carried through with least interruption to traffic and with the best ultimate results. While the plans are being perfected and carried out the railroad has offered to equip its locomotives with oil or coke as a fuel so as to make them less objectionable to the public.

New York Electrical Society.

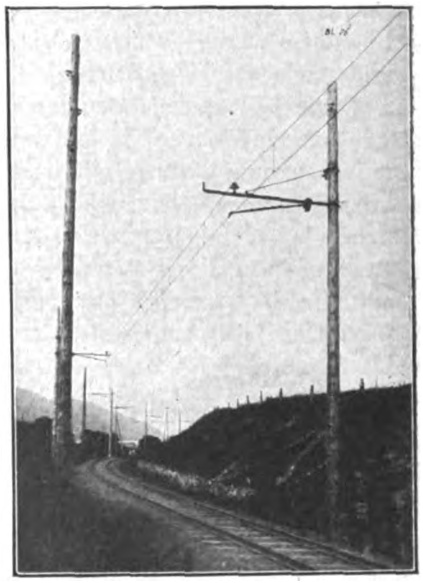
The two hundred and eightieth meeting of the New York Electrical Society, on invitation of the Electrical Testing Laboratories, was held at the laboratories, Eightieth Street and East End Avenue, Tuesday evening, November 24. Wilson S. Howell made a short address welcoming the society and explaining briefly the very wide range of work done by his company. While testing incandescent lamps is a very large part of their business, over 17,000,000 having passed through the laboratories last year, their work is by no means confined to testing incandescent lamps. Every possible design of lamp from the kerosene lamp to the latest development in arc lights is brought to them for test and measurement. All kinds of metals and composition material are tested, as well as measuring instruments of all kinds, shades and reflectors, insulators and insulating material; in fact, all material that goes into the construction of electrical apparatus is tested not only for the engineer and the manufacturer, but also for the purchaser. The point of Mr. Howell's remarks showing the wide range of their work was that the value of testing, both for the engineer and manufacturer, as well as the user of apparatus, is becoming more thoroughly appreciated.

Dr. Clayton H. Sharp gave a most interesting address, discussing apparatus for measuring spherical candlepower, the integrating sphere, methods of measuring illumination values, etc. After this address the members inspected the laboratories, where could be seen in operation every known form of testing apparatus. The members were also given a treat in the shape of an elaborate collation.

A NORWEGIAN SINGLE-PHASE RAILWAY.

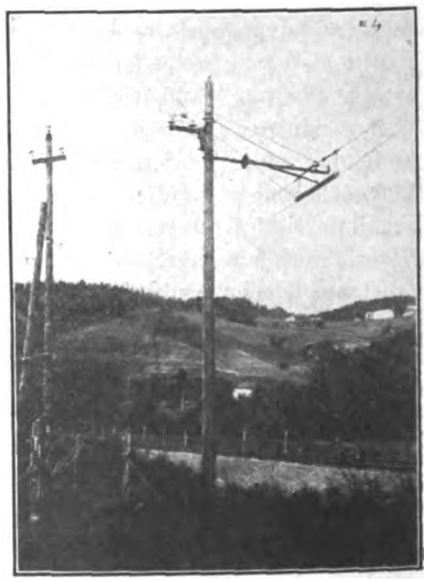
BY A. WEBSTER.

For some time past, a waterpower electric generating station has been in operation at Skjenald Fossen, near Thamshavn, in Norway, its object being to sup-



THAMSHAVN SINGLE-PHASE RAILWAY—OVERHEAD CONSTRUCTION ON CURVE.

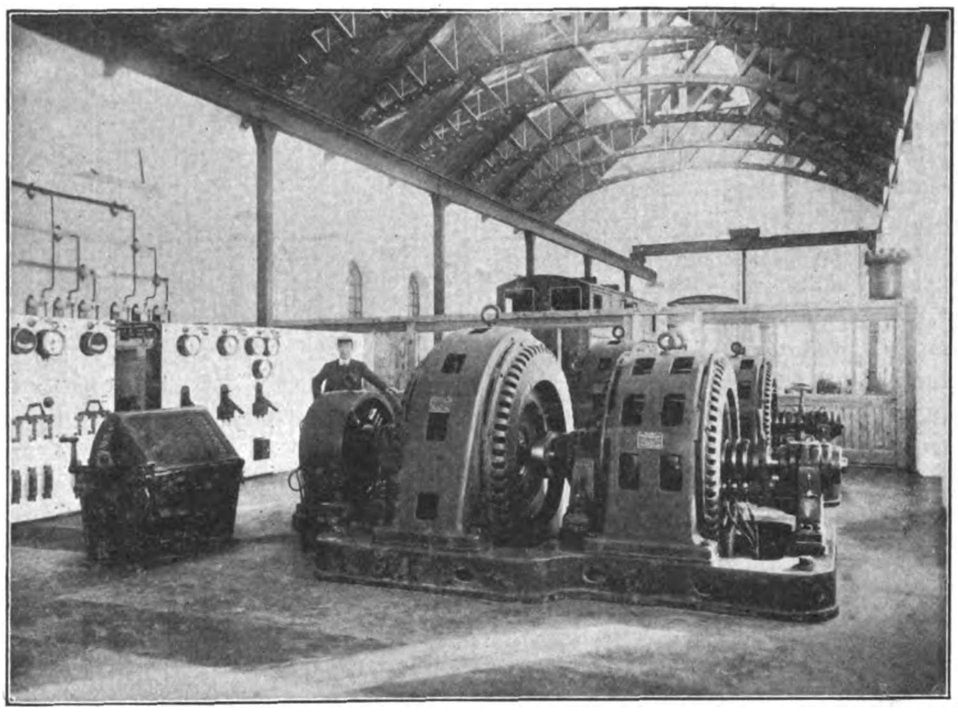
ply Thamshavn and the villages en route to Lokken, where there are a considerable number of mines. The district is also one much visited by tourists, and electric power being available, it is not surprising that an electric railway between these two points should be thought of. Two gentle-



THAMSHAVN SINGLE-PHASE RAILWAY—OVERHEAD CONSTRUCTION, SHOWING SECTION INSULATOR AND HIGH-TENSION SHORT-CIRCUITING SWITCH.

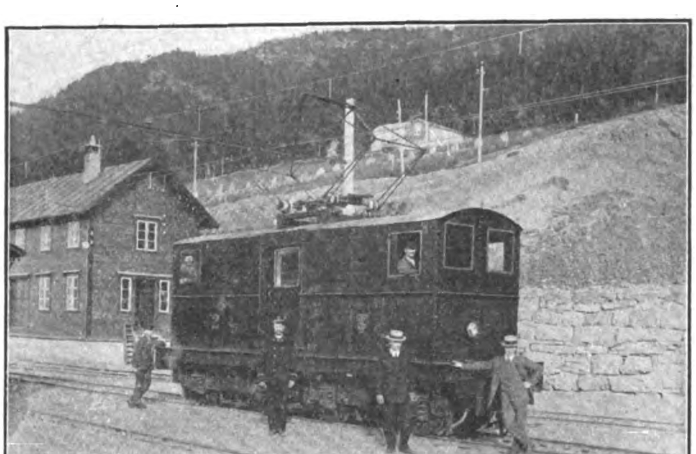
men interested in the district accordingly went into the matter and finally decided to place an order with the British Westinghouse Electric and Manufacturing

Company for the construction of a single-phase line. The order was placed and the line put into operation within twelve months, in spite of the climatic conditions prevalent during certain months of the year in this part of Norway. The line constitutes the first electric railway in Norway.

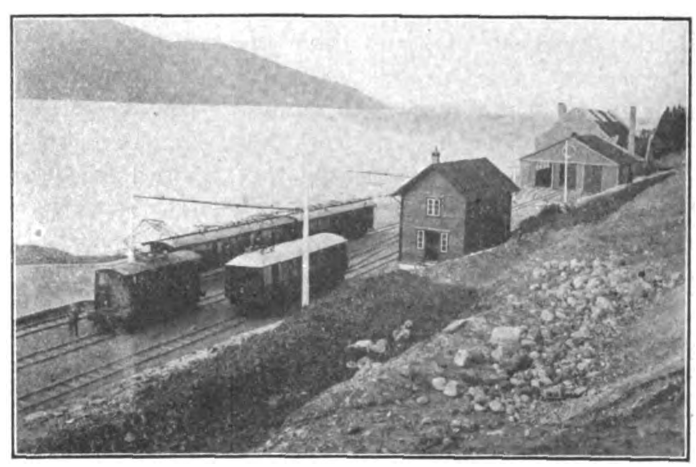


THAMSHAVN SINGLE-PHASE RAILWAY—MOTOR-GENERATORS IN SUBSTATION.

Thamshavn is some twenty miles distant from Trondjem, a well-known east-coast Norwegian watering place, and the railway is some sixteen miles in length to its other terminus at Lokken. The whole district is rich in minerals and timber, and so it is that arrangements have been made for dealing with large quantities of merchandise. In this connection there is a regular service of steamers between Trondjem and Thamshavn. The power station already mentioned is about five miles to the west of Thamshavn, and supplies three-phase current at 15,000 volts, fifty cycles, direct to the railway substation at Thamshavn, where transformation takes place to single-phase current at 6,600 volts, twenty-five cycles, for feeding to the overhead trolley wire. An interior view of the substation is shown.



THAMSHAVN SINGLE-PHASE RAILWAY—TWENTY-TON SINGLE-PHASE LOCOMOTIVE.



THAMSHAVN SINGLE-PHASE RAILWAY—TERMINUS AT THAMSHAVN ON ORKEDALS FJORD.

Metre-gauge track has been laid, flat-bottomed steel rails being fastened to wooden sleepers laid on ballast. With the exception of double track and sidings at the stations, the line is single throughout, there being very few difficult gradients or curves to contend with for the greater portion of the way.

The overhead construction consists of hard-drawn, grooved copper wire of sixty-five square millimetres section, suspended from a steel cable. As will be seen from the photographs, the insulators supporting the steel cable are carried on steel brackets attached to wooden poles, the spans varying from 150 feet to sixty-eight feet, according to whether the track is straight or curved. The normal height of the trolley wire above the track is 5.5 metres.

A feature of the rolling stock is the provision of a motor coach for first-class passengers the interior of which is divided into a vestibule and driver's compartment at each end and two salon compartments with a lavatory between. This car is fitted with two forty-horsepower motors. The rolling stock also includes three twenty-ton locomotives, one of which is illustrated, for hauling the freight and passenger trains. Each of these locomotives carries four forty-horsepower motors, mounted on two trucks. Both on the locomotives and the salon coach the current is collected by a pantagraph bow and passes through an automatic circuit-breaker located inside the driver's cab. There the high-tension wiring is reduced to only ten feet in the case of the locomotives. The four motors are arranged permanently in two groups, two in series, cut-outs being provided, by means of which either pair may be isolated when desired. These locomotives are designed to exert a tractive effort of 6,500 pounds at ten miles per hour and a maximum tractive effort at starting of 8,000 pouuds.

The substation forms part of the workshops at the Thamshavn terminus, and the plant installed consists of two 15,000 to 6,600-volt, oil-insulated, three-phase transformers and two 250-kilowatt motor-generators, capable of carrying an overload of 100 per cent for short periods. There is sufficient space, however, for an additional motor-generator to be installed. These units consist of a three-phase induction motor, fitted with slip-rings and liquid rheostat for starting, direct-coupled to a single-phase, revolving-field generator.

PUBLIC SERVICE COMMISSION, FIRST DISTRICT, STATE OF NEW YORK.

SECOND VOLUME OF REPORT FOR SECOND HALF OF 1907.

The second volume of the report of the Public Service Commission, First District, State of New York, for the first six months of its existence, ended December 31, 1907, has been issued. From figures compiled from statistics presented by the companies under its control the commission states that the number of car rides per individual in New York in 1907 was 317; in 1902 was 266, and in 1890, 234.

The report shows that every extension and improvement of transit facilities brings increased travel quite apart from the natural increase in population. In the last seventeen years the passenger traffic has more than doubled. The total number of passengers carried by all lines in the greater city in 1907 showed an increase of 124,505,734, an average daily increase of 341,000 passengers. This includes regular fare and transfer passengers. The increase in the regular fare passengers was 65,778,979, or about 180,000 per day.

New York city, with one-half of the population of the state, accounts for four-fifths of the traffic conducted by the street railways of the state, which in turn is almost equal to the number of passengers carried by the entire tramway system of England and Wales.

The number of rides per capita in New York city (317 in 1907) is larger than in any other American city, with the possible exception of San Francisco, and greatly exceeds that of any city in Europe.

The street railroads of New York city embrace underground, elevated and surface systems operated by electricity and steam and horsepower. The underground system, known as the subway, which is owned by the city and operated by the Interborough Rapid Transit Company, embraced at the end of June, 1907, twenty-two miles of road in Manhattan and the Bronx.

The total length of roads operated by the railroads and street railroads under the jurisdiction of the commission aggregated 763 miles. As most of the line is double-tracked, and some of it laid with a third and fourth track, the total trackage is more than double the length of the road. Including sidings and turnouts and reducing all tracks to single-track mileage the total length of track was 1,612 miles.

In the borough of Brooklyn the total trackage of the Brooklyn Rapid Transit system is 564 miles, and that of other companies fifty-five miles. The borough of Queens, on all surface lines except the Brooklyn Rapid Transit system, has 147 miles, while the borough of Richmond has seventy-three miles of steam roads and sixty-two miles of electric roads. Omitting bridge trackage and combining the mileage of Manhattan and the Bronx, the length of road in these two boroughs amounts to 321 miles, as compared with 282 miles in Brooklyn, ninety-six miles in Queens and sixty miles in Richmond.

The new mileage put into operation in 1907 (nearly seventeen miles of track) was only a small part of the mileage under construction. Excluding the work done upon the new McAdoo and Pennsylvania tunnels, the companies already in operation expended $4,700,000 upon construction and reconstruction.

While the proprietary companies in 1907 charged to their capital accounts more than $2,000,000 for cars, the number of cars reported available for service was smaller than in the preceding year. The total number of cars available was 10,009, but not all of these are in service at any time, as more than one-quarter are of the open type, and used only in summer. The subway reports 794 cars; the elevated in Manhattan and the Bronx, 1,503; the surface lines in Manhattan, 3,280, and the surface lines in the Bronx, 786. The total number of all cars available in Brooklyn was 3,050; in Queens 313, and in Richmond 283. The Manhattan surface lines had 349 less cars in 1907 than in 1906.

The fluctuations of travel are shown in a table giving the number of passengers carried each year on the Manhattan elevated roads since 1892. In that year, the total number of pasengers carried by the elevated was 213,692,745. In 1893, it increased to 221,407,197, but from that year on there was a steady decline until in 1899 the total was 174,324,575; an increase then set in and continued up to 1904, when the total was 286,634,195. Here another decline set in and the travel decreased until 1906 when 257,796,754 passengers were carried. In 1907 the figures showed 282,924,273.

The report says the decline from 1893 to 1899 is explained by the extension of the surface lines and the improved service they rendered by reason of the substitution of electric for animal traction. The second decline in 1904 was due to the opening of the subway, which took a great many passengers from the elevated, but in two years the elevated roads recovered virtually all the lost ground.

Transfers are shown to have increased during the year 1907. While the number of regular fare passengers showed an increase of 5.2 per cent, the number of transfer passengers increased 18.9 per cent. The smallest percentage of transfer increase was in the Bronx (5.6 per cent) and the greatest increase in Richmond, where the number of transfers nearly doubled. Of the total increase in transfer passengers, namely, 58,700,000, Brooklyn furnished seven-tenths, yet the use of transfers in Brooklyn is still less than that on the Manhattan surface roads. Of the latter there are fifty-one transfer passengers to each 100 fare passengers, while in Brooklyn the ratio is only thirty-five to 100, but in Brooklyn, the figures include both elevated and surface roads.

Military Telegraphers Dine.

On the evening of November 27 the Old-Time Telegraphers' Association and the Society of the United States Military Telegraph Corps tendered a banquet to Andrew Carnegie, to bid him Godspeed and celebrate his seventy-first birthday. The banquet was held at the Manhattan Hotel, New York city, and four of the original members of the United States military telegraphers who responded to the call by Mr. Carnegie on April 22, 1861, for operators, were present. These were Col. William Bender Wilson, Richard O'Brien, Jesse W. Crouse and David Homer Bates. There were twenty-six other veterans of the Civil War Military Telegraph Association present, together with a couple of hundred members of the Old-Time Telegraphers' Association. Col. Robert C. Clowry, president of the Western Union Telegraph Company, presided, and addresses were made by Thomas A. Edison, W. C. Brown, William R. Plum, Richard O'Brien, Mr. Bates, Colonel Wilson, William J. Dealy, Charles P. Bruch and Col. A. B. Chandler.

In closing the speech-making, Mr. Carnegie delivered a characteristic address, and expressed his appreciation of the tribute paid him by his old comrades.

After songs by Miss Leila L. Morse, granddaughter of Prof. Samuel F. B. Morse, inventor of the telegraph, all joined in this song to the tune of "Auld Lang Syne:"

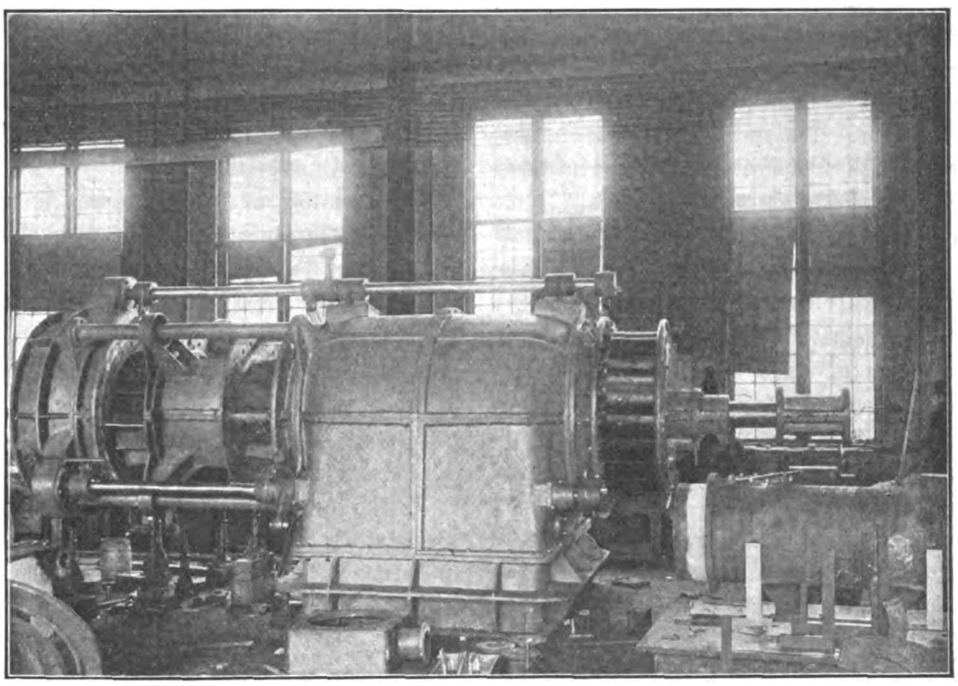
God grant our honored guest the peace
His life has fairly won.
And crown him with Thy blessings,
For the noble deeds he's done.
'Tis not a nation, but the world,
To him should grateful be.
Oh, may he live yet many years,
Sustained by "Seventy-three."

Hydraulic Turbines at Priest Rapids, Washington.

The photograph reproduced herewith shows as it appeared during construction one of the vertical triplex Allis-Chalmers hydraulic turbines for open flume which has been installed at Priest Rapids, east of North Yakima, Wash., for the Hanford Irrigation and Power Company. This company is a Seattle corporation and has lately completed the work of building and equipping a new power house on the Columbia River at the rapids mentioned. This development has a present capacity of 2,000 horsepower, which will eventually be increased many times over. The irrigation project in connection with it embraces 16,000 acres of land and has a capacity for watering another 16,000 acres with a small addition to the present equipment. The company has also completed a pumping station at Coyote Rapids on the Columbia River, fourteen miles below the Priest Rapids, and has already in service transmission lines for electric power from Priest Rapids to this station.

The entire equipment for the new plant was contracted for at one time and from one builder. The latter's engineers, in conference with H. K. Owen, consulting engineer, of Seattle, laid out the entire plant for a hydro-electric pumping station of the type best adapted to the local conditions. Vertical triplex hydraulic turbines are set in open flume, each direct-connected to a vertical Allis-Chalmers alternator, each set being designed to meet the following normal conditions: Fall fifteen to thirty-two feet, power 1,000 to 2,200 brake-horsepower, speed 150 revolutions per minute. At fifteen-foot head each turbine develops 1,000 horsepower, at full gate and with a speed of 150 revolutions per minute. The vertical alternators are rated at 900 kilowatts and wound for sixty-cycle, three-phase current at 2,300 volts. The governor used is of the Allis-Chalmers oil-pressure type.

An exciter turbine and direct-connected generator is installed, designed to operate under twenty-one-foot fall, with a discharge of fifty-two cubic feet per second, and rated at 100 horsepower. A motor-generator exciter set of small capacity has also been provided. The transmission line mentioned above carries the current from the main station fourteen miles at 22,000 volts. This line is supported by eucalyptus pins and the cross-arms used were boiled in oil. The wires are arranged in a triangle. The poles are thirty-five feet high.



VERTICAL TRIPLEX TURBINE FOR OPEN FLUME, EIGHTEEN TO THIRTY FOOT HEAD; CAPACITY, 1,000 TO 2,100 HORSEPOWER—HANFORD IRRIGATION AND POWER COMPANY, HANFORD, WASH.

The pumping equipment consists of four single vertical-shaft suction pumps with thrust bearing. Two units have a capacity of fifty-two-and-one-half cubic feet each per second, against a total head of thirty-four feet. Their speed is 175 revolutions per minute and the diameter of the suction and discharge nozzles is thirty inches. These pumps are direct-connected to 450-horsepower Allis-Chalmers induction motors. The water is admitted at the bottom of the pump and the discharge casing is of the snail-shell type. The complete casing rests on three feet securely bolted to the foundation and held rigid. The remaining two pumps are of the same general type for high-lift service; each has a capacity of thirty-six cubic feet per second, against a total head of eighty-one feet and operates at a speed of 514 revolutions per minute. These pumps are direct connected to 550-horsepower induction motors. The bilge pumps are of the vertical motor-driven centrifugal type. They have bottom suction and open impeller. Direct-current, 110-volt, fifty-one-horsepower compound motors are used to drive them at 850 revolutions per minute. These pumps have a capacity of 150 gallons per minute against a thirty-five-foot head.

Proposed German Tax on Electricity and Gas.

The *Elektrotechnische Zeitschrift* of November 12 is accompanied by a supplement, which contains a reprint in full of a bill just introduced in the German Reichstag and having for its purpose the establishment of a tax on electricity and gas. It is proposed to levy a tax of five per cent on the selling price of electric current, with a maximum of 0.4 pfennig per kilowatt-hour. Current generated for private use is to bear a tax of 0.4 pfennig per kilowatt-hour, with a reduction to five per cent of the cost of production, when it can be proven that the above rate is in excess of this percentage. Gas is to bear the same rate of taxation per cubic metre of gas sold as the kilowatt-hour of electricity. Electrical installations of not over one-and-one-half kilowatts capacity are to be exempt from taxation. If the product is imported from a foreign country, the receiver is to pay the tax; if it is exported, the exporter is to pay the tax. All electrical illuminants, as well as incandescent bodies for gas, alcohol and oil lamps, are also to bear their burden of taxation. On the basis of statistics appended to the bill it is estimated that the net revenue to the German Government from this source will be about fifty million marks annually. The statistics show the number of generating stations existing in Germany in 1907 to be 1,530, with a capacity of 858,841 kilowatts and connections of a value of 1,100,861 kilowatts. The average cost of generating a kilowatt-hour in 1906 was 12.91 pfennig, and the average receipts per kilowatt-hour were 28.29 pfennig. The available water-power in Germany is stated to be 1,931,000 horsepower, of which 490,100 horsepower, or about twenty-five per cent, is now being utilized.

SMOKELESS COMBUSTION.

BY CHARLES L. HUBBARD.

So much has been said of late in regard to smoke abatement that a review of the subject may be of some interest and of practical value to those in charge of power plants which are located in or near large villages and cities.

It is probably true that comparatively few firemen in charge of the average plant are familiar with the nature of the chemical actions which take place in the boiler furnace during the process of combustion. While such knowledge is not absolutely necessary in order to avoid the formation of smoke, an understanding of the elements of any process is always the first step in successfully carrying on the same, whether it be the manufacture of some article, the running of a machine, or the burning of coal under a boiler.

A careful investigation of the matter of smoke consumption as reported by various experts lays particular stress upon firing and furnace construction, and these will be taken up briefly along the lines especially affecting the formation or prevention of smoke.

First, let us consider the process of combustion without reference to where it takes place or to the nature of the fuel. Chemically speaking, combustion is the combination of oxygen with certain elements which produce heat and light. The substance with which it combines is called the combustible, or when combustion takes place in an ordinary furnace it is called fuel. The chief elements of a fuel are carbon and hydrogen, and the products of perfect combustion are water, which consists of two atoms of hydrogen and one of oxygen (H_2O), and carbon dioxide or carbonic acid, as it is usually called, which is a gas made up of one atom of carbon and two of oxygen (CO_2). In the process of combustion, as it takes place in a furnace, the oxygen is taken from the air which enters through the draft doors, and this unites with the carbon and hydrogen in the full, forming carbon dioxide and water.

In order to secure perfect combustion, oxygen must be present in just the right proportion to unite with the elements of the fuel, as stated above. If there is not a sufficient air supply, carbon monoxide (CO) will be formed instead of CO_2, and this greatly reduces the quantity of heat produced. For example, if a pound of carbon is converted into CO, it will generate 4,400 heat units, but if double the amount of air is supplied, CO_2 will be formed and 14,600 heat units will be given off, provided the temperature is maintained at the proper point. On the other hand, if too much air is supplied, it lowers the temperature below the point necessary for complete combustion, and so the results may be no better than when the air supply is too small.

When combustion is not complete, some of the hydrogen, together with the carbon with which it is usually combined (called hydrocarbon), may be distilled from the coal and not burned, or the hydrogen only in this volatile matter may be burned, leaving the carbon in the form of soot or smoke, to be carried off in the gases passing out of the furnace. Smoke is a sure evidence of improper combustion, but it does not follow that where there is no smoke combustion is perfect. The perfect combustion of coal in a furnace can only be effected by a sufficient supply of oxygen supplied under proper conditions. The most important of these are a high temperature and an intimate mixture of the air with the fuel.

Coal is a compound substance and may be decomposed by heat into several distinct constituents, but in combustion we deal principally with but two—carbon in the form of coke, and hydrogen, generally known as gas. These two elements practically contain the full heating properties of the coal. We say that when coal is thrown upon a fire it commences to burn, but before any burning takes place it is decomposed into its constituent elements. The gas, having been distilled by the heat of the fire, burns first by its chemical union with the oxygen of the air, forming water. The gas having been disposed of, the coke burns in a similar manner, forming carbonic acid.

In order to ignite a substance and keep it burning it must be heated to a certain kindling point and kept up to that temperature. While the gas is being expelled from the coal the latter remains at a relatively low temperature; no particle of solid coal can burn while gas is issuing from it. A lump of coal may, however, be giving out gas in one place while it has been expelled from another and the remaining coke has already ignited. Coke does not produce smoke in burning; this is only formed during the distillation of the gas. To support combustion it is necessary to maintain a temperature of at least 800 degrees Fahrenheit. At temperatures lower than this there can be no burning of the coal. It is common in furnaces to have a temperature of 3,000 degrees Fahrenheit and over, just above the bed of live coals on the grate.

The amount of air required by a pound of soft coal to completely burn it is approximately twelve pounds, or 150 cubic feet. The actual amount needed in practice depends upon the force of the draft and upon how thoroughly the air and the gases are mixed. Former practice with ordinary chimneys allowed twenty-four pounds of air per pound of coal. With improved draft and better grates this has been reduced to eighteen pounds, and where combustion tubes or steam jets are used above the fire fourteen pounds has sometimes been found sufficient. The disadvantage of using too much air is the cooling of the fire, which retards combustion and reduces the transmission of heat, and second, the reducing of the chimney draft by cooling the stack. Every extra pound of air has to be heated by the fire, and this heat passes up the chimney without being used.

The quantity of air, however, should vary with the condition of the fire. Just after firing, when the gases are being distilled rapidly from the coal, more air must be admitted; after the coal becomes incandescent a comparatively small supply is needed.

The object to be attained in smokeless combustion is to prevent the formation of smoke rather than to provide means for burning it after it has been allowed to form. That smoke can be burned if carried into a very hot chamber and brought in contact with a sufficient quantity of highly heated air may be shown by the following simple experiment: First, place a short piece of candle inside of a tall narrow cylinder. The deficient air supply which the candle receives under these conditions will cause it to give off a column of black smoke. If this is led into the central draft tube of a Rochester kerosene lamp and passed up into the flame it will be completely burned.

The action of combustion and the effect upon it of different conditions is well illustrated by a kerosene lamp, and although this example has often been made use of, it may well be repeated in the present case. If we take a lighted central draft lamp and adjust the wick to such a point that it gives a rather short and clear white flame without a trace of smoke, then gradually obstruct the opening at the bottom, the following result will be observed: First, the flame will grow longer and its color change from white to yellow, and then to red, and it will also begin to smoke. Finally, when the air supply is nearly shut off the flame will rise almost to the top of the chimney, at the same time giving off a column of dense black smoke and soot. In this example the wick represents the automatic stoker, supplying fuel automatically; the perforated gauze at the base of the burner is the grate which heats and regulates the air supply, while the chimney regulates the force of the draft. The smoky flame caused by turning up the wick is analogous to that caused by adding too much coal at one time to a furnace. If the supplies of air and fuel are properly adjusted to each other the flame will burn clearly and steadily without a trace of smoke. If on the other hand the wick remains the same and the chimney is raised from the base, smoke will again appear, because cool air rushing in above the gauze checks combustion by cooling the flame. If a cold metal rod or strap be passed down the chimney into the flame it will become coated with soot, due to the chilling effect upon the burning gases. In like manner, too close proximity of a crown sheet to the fire causes soot in a boiler furnace.

We see from the above that perfect combustion may take place rapidly with a short flame and slower with a long flame; also that imperfect combustion takes place with a very long flame of a low temperature with the same amount of fuel, but with different results as regards the production of light and heat. The principles learned from these simple experiments with the flame of a lamp are of great importance in connection with the study of the action of boiler furnaces. Having become somewhat familiar with the process of combustion from its theoretical side, let us now apply the various results noted to the actual burning of coal in the furnace of a steam boiler.

Bituminous coal contains usually from fifty-two to eighty-four per cent of free carbon and from twelve to forty-eight per cent of hydrocarbons. When this is burned in a common furnace the coal is first heated and the hydrocarbon gases are driven off in such quantities that not enough heated air can reach them to give perfect combustion, and dense clouds of black smoke will escape through the chimney. A large amount of heat is thus lost until all of the hydrocarbons have been driven off, when the chimney will stop smoking and combustion become more perfect until a fresh charge of fuel is dropped on the hot coke, when the same performance will be repeated. This result is more evident as the volatile matter in the coal increases, hence bituminous coal produces large volumes of smoke, while anthracite gives off but little. The waste caused by a smoking chimney is due to the escape of unburned gases rather than to the carbon which appears in the form of soot and smoke, the latter being usually less than one-half of one per cent of the coal burned on the grate.

Let us suppose we have an ordinary flat grate of the old-fashioned type without stoker or smoke-preventing device of any kind. Let there be a clear, even fire, with plenty of air coming up through the grate to complete the combustion of the coke. The fireman opens each door in turn and covers the whole surface of the fire with a layer of fresh coal. Additional air is needed to supply oxygen for this sudden increase of fuel, but the stopping of the air passages by the fresh coal prevents even the usual amount from passing through the grate. At the time when air is most needed least is supplied, and dense smoke is the result. A similar occurrence takes place at the time of starting up a fresh fire after cleaning.

Now let the fireman when he comes to replenish the fire put in one or two shovelfuls, and that on one side, leaving the other side red and bright. Let him also open wide the damper and get a free draft, and if the fire shows signs of smoking, leave the furnace door open an inch until the smoke has burned off. The next time let him fire the other side in the same manner. Likewise when he cleans the fire let him do but one side of the grate at a time and build his new fire with one or two shovelfuls at a time, keeping it bright and clean.

To be a good fireman, one should possess a rudimentary knowledge of the principles of combustion, although such knowledge may be more of a practical than a theoretical nature. The fireman should be able to demonstrate his ability to put such knowledge to good use by firing skillfully, placing each shovelful of coal where it will give the best results; promptly filling every hole in the firebed through which cold air may find an entrance; keeping the fuel bed level and the firebox temperature up to a desirable degree by skillful use of the furnace doors, ashpit doors and damper. He should avoid unnecessary slicing, but at the same time keep the fuel bed sufficiently open for the free and even passage of air. He should also be able to tell the condition of the fire closely by watching the ashpit.

On the other hand, with the best effort the fireman may be unable to produce satisfactory results as regards smoke because he is given too much to do; that is, in a large plant a man may be given too many furnaces to feed, and in a small one he may be given other duties that interfere with handling the fires in a proper manner. A case was reported some time ago where satisfactory conditions as to smoke production were brought about by reducing the grate area cared for per man from seventy-five to forty-seven square feet each in the case of hand-fired furnaces.

[To be continued.]

Westinghouse Directors Elected.

At the meeting of the Westinghouse Electric and Manufacturing Company held at East Pittsburg, November 30, the stockholders took final action prior to the termination of the receivership.

Resolutions were passed amending the by-laws of the company so as to allow the election of sixteen directors and to provide for the election of a proxy committee. The following board of directors was elected: For the class whose term expires July, 1909, Richard Delafield, E. C. Converse, Anthony N. Brady and J. D. Callery; terms expiring July, 1910, A. G. Becker, George M. Verity, William McConway and Charles A. Moore; terms expiring July, 1911, Charles F. Brooker, James S. Kuhn, Edward F. Atkins and E. M. Herr; terms expiring July, 1912, George Westinghouse, Neal Rantoul, Joseph W. Marsh and Albert H. Wiggin.

The election of a proxy committee resulted as follows: James N. Jarvie, Jacob H. Schiff, Charles Francis Adams, Robert S. Smith and F. W. Roebling.

Indiana Electric-Light Men Organize.

A large number of managers, superintendents and owners of electric-light plants in Indiana held a meeting at the Denison Hotel, Indianapolis, November 26, and formed the Indiana Electric Light Association. Thomas McReynolds, of Kokomo, was elected president, and Frederick Leslie, of Muncie, secretary and treasurer. The purposes of the association are defined to be educational, making for the discussion of scientific, experimental and electrical subjects. The members of the association are sanguine that sufficient interest will be taken in the associaton to make it a success, and believe the meetings for the exchange of ideas and methods of operation will prove helpful to electric lighting throughout the state.

QUESTIONS AND ANSWERS.

Ayrton Universal Shunt.—In the answer to the query of M. A. G., relative to the Ayrton Universal Shunt that was published in this column on November 14, a typographical error was made in the first equation. It should have been given thus:

$$\frac{I_g}{I_s} = \frac{s}{g + r - s}$$

The first member of the equation was unfortunately inverted. The equation is based on the principle that the currents in the two branches of a divided circuit are inversely proportional to the respective resistances. The subsequent equation, as previously correctly stated, is derived from this by the rules of proportion.

Use of Leather Belting.—Kindly advise me as to which is the proper side of a leather belt to be placed against the pulley face.—R. E. B., Carthage, Mo.

The two surfaces of a leather belt are called the flesh side and the grain or hair side. The latter is harder but not as strong in tensile strength as the former. For both these reasons the grain side should be placed against the face of the pulleys. Being a harder surface it is better adapted for the wear of attrition. At the same time the flesh side being much stronger, is better adapted to withstand the greater tensile stress to which the outside of the belt is subjected.

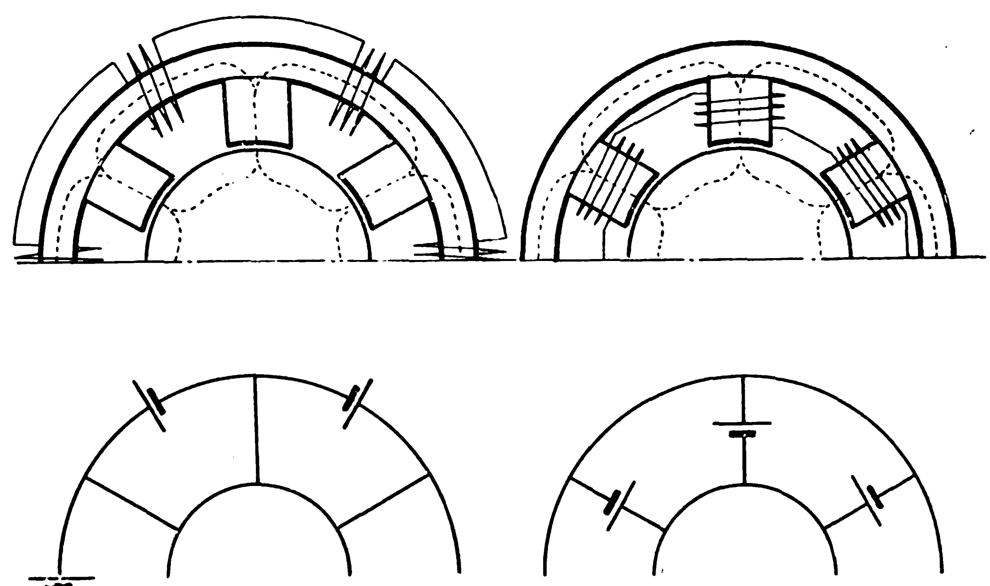
Induction Motors.—1. Can the stator of a three-phase induction motor be connected delta? 2. If some of the copper bars are grounded through faulty insulation, what effect will it have on the rotor? 3. If current lags or electromotive force lags on a three-phase induction motor, will it cause fuses to blow? The motor generally runs from no load to twenty-five per cent overload, the fuses being heavy enough to carry forty per cent overload.—T. J. S., Dixon, Ill.

1. The stator may be either delta or Y-connected. 2. In the rotor the difference of potential developed between the conductor bars and the laminated core is very small, since the entire rotor, both copper and iron, acts as the secondary of a transformer. In the squirrel-cage type, moreover, the copper bars are entirely short-circuited by the end rings, so that the grounding of a few of them would produce little, if any, effect. In a rotor having an auxiliary resistance the grounding of a few bars might short-circuit some or all of the resistance so as to lose the value of the latter in keeping down the starting current. 3. The current in an induction motor invariably lags, but this should not cause any fuses to blow in normal operation unless the angle of lag is excessive on a very heavy overload. In this case the current would become exceptionally large and might cause the opening of the fuses. In the case cited, if the power-factor is not immoderate, there will be no occasion for the blowing of fuse.

Wiring Rules.—1. The following formula has been used by the writer for a number of years in calculating the size of wire used in direct-current wiring:

$$A = \frac{I \times D \times K}{V},$$

where A = area of wire in circular mils, I = amperes on line, D = distance in feet, V = voltage, and K = 21.62, a constant for direct current. Recently an insurance inspector told me specifically "that it was at fault when applied to No. 14 or No. 12 B & S wire, claiming that in practice the actual drop was about three times the theoretical result. Is this formula incorrect, or can you suggest a better one?



ARRANGEMENT OF FIELD COILS AND ELECTRICAL ANALOGY THERETO.

2. A certain architect's specifications call for "100 candlepower and 250 candlepower at each outlet—i. e., the size of wire and number of circuits to be large enough for the above candlepower lamps to be used." What authority will govern the interpretation of these words? For instance, if tungsten lamps are used in place of carbon-filament lamps, there is a difference between one-and-one-fourth and three-and-one-half watts per candle, with a corresponding difference in the number of circuits and size of wire. If the circuits were filled up to the capacity of 660 watts with tungsten lamps, would this be necessarily hazardous or against the National Code?

3. Kindly calculate for me the voltage at the last lamp on a two-wire circuit 100 feet long having twelve sixteen-candlepower, three-and-one-half-watt lamps connected to it, when the voltage at the tablet board is 115 volts, direct current and No. 12 B & S wire being used. Also what would this voltage be, if No. 14 wire were used?—H. K., Harrisburg, Pa.

1. The formula is correct and applies to any copper wire carrying direct current, provided K has the value given and V is the voltage drop in the line. It is derived directly from the fundamental laws of resistance and is frequently given in different but substantially equivalent forms. Thus, in place of V in the denominator, PE is sometimes used, where E is the voltage at the receiving end and P the percentage of line drop; in this case K has a value 100 times that given.

2. Rule 21d of the National Electrical Code limits incandescent lamp circuits to 660 watts without specifying the type of incandescent lamps to be used. It is the general practice for inspectors to allow such circuits to be loaded up to 660 watts with tungsten as well as other such lamps. The only hazard there is in this practice is the danger of substituting carbon-filament lamps of nearly equal candlepower for the tungsten lamps; this would, of course, overload the circuit. This procedure would be very unlikely, however, since a person that has once used tungsten lamps would probably not go back to the use of carbon lamps.

3. Assuming the lamps to be uniformly distributed at a distance of eight-and-one-third feet from one another, and considering each lamp as taking one-half ampere, the voltage at the last lamp would be 113.97 when No. 12 wire is used and 113.36 volts when No. 14 wire is used.

Dynamo Field Design.—Which is the more effective position for the field coils of a multipolar dynamo, assuming they are to have in either case the same number of ampere-turns—placed on the poles, as appears to be the more general practice, or linking the yokes, as I have seen in the case of a few machines. The latter seems to me to be preferable, as I believe it makes possible a saving in the length of the turn, and, hence, the total field copper. The cross-section of the yoke is necessarily only one-half that of the poles; consequently, assuming the same number of ampere-turns per winding will produce equal flux values in either case (the total number of coils being the same in either arrangement), the length of the pole-turn must be $\sqrt{2}$ times the length of the yoke-turn. As the resulting difference in the respective windings would be $\sqrt{2} - 1$, or nearly forty per cent, it appears that this yoke arrangement of coils would effect a substantial saving.—V. R. L., Augusta, Me.

Given coils of the same number of turns and traversed by equal currents, that is, of the same ampere turns, and placed on either the poles or the yokes of the machine as contemplated in the query, the yoke arrangement of the coils will set up only half the flux which would be produced by the pole arrangement. It must be remembered that flux "flows" as a result of magnetomotive force after a fashion analogous to the electrical phenomena of Ohm's Law. With magnetic circuits of equal reluctance the greater the magnetomotive force the greater the flux. It will be noted that in each of the local magnetic circuits formed by the yoke, pole pieces and armature, there are two sources of magnetomotive force (coils) per circuit in the case of the pole arrangement, while there is only one magnetomotive coil in the yoke arrangement. Since in each circuit the coils are placed in series cumulatively, having the same magnetic direction in each local path, the total magnetomotive force per circuit will be twice that of the yoke arrangement, and if the reluctances of the paths are equal the resulting flux will be correspondingly doubled.

An electrical analogy forms a convincing demonstration of this fact. In the electrical circuits shown the reader will detect an analogous relation to the magnetic paths, the coils or seats of magnetomotive force being represented by ideal cells (having no internal resistance) as seats of electromotive force. Considering the local circuits to be of equal resistance, a little examination will show that the currents which flow in the radial paths are twice as great in the "pole" arrangement of cells as in the "yoke" arrangement. Carrying back the analogy of current to flux, it will appear that there would be no theoretical gain but a fifty per cent loss in the yoke arrangement, while the mechanical disadvantages of putting the coil in this position are very great. As the inquirer says, the field yoke need be only half the area of the pole from magnetic considerations if the same quality of iron is used, but this relation is seldom given for structural reasons, since to gain stiffness the yoke or frame, made of a cheaper material of lower permeability than the poles, is given a comparatively large cross-sectional area and perimeter. Moreover, the magnetic leakage with the tangential coil arrangement is nearly twice as great as that with the radial coil design. For all these reasons the latter is almost exclusively used.

Relation of Current and Potential.—In the article on "Alternating Currents and Their Applications" the diagram, Fig. 16, on page 687, shows the current curve, which is dotted, as leading the impressed electromotive-force curve 1TS. Kindly inform me whether this can be correct for the supposed inductive circuit?—A. J. S., Indian Head, Md.

In the diagram referred to the axis OX represents time as measured from the point O as origin. The curve 1TS is further to the right than the corresponding half of the dotted current curve, and therefore leads the latter as it should. The electromotive force in this case leads the current by about twenty-seven degrees.

To Honor Wright Brothers.

In recognition of the achievements of the Wright brothers in their record aeroplane flights in France and this country, the Aero Club of America is now obtaining designs for two gold medals, which will be presented to Wilbur and Orville Wright at a banquet to be given in their honor early next year. President J. C. McCoy has appointed a committee to raise subscriptions from the 300 club members. The medals will cost about $1,000 apiece.

DeWitt C. Morrell is chairman of the Medal Committee, and the other members are Prof. Alexander Graham Bell, Peter Cooper Hewitt, Gutzon Borglum, Major B. Hersey, Charles J. Glidden, Christopher J. Lake, Octave Chanute, James Means, Albert F. Zahm, Charles M. Manly and Alan R. Hawley.

Invitations will be extended to all of the affiliated aero clubs in the country to send representatives, and an effort will be made to obtain one or more foreign delegates for the dinner.

Wilbur Wright has already received medals in honor of his notable flight from the Aero Clubs of France and Great Britain.

Hydraulic and Electric Machinery.

In his presidential address, given before the Yorkshire students of the Institution of Civil Engineers at Leeds, A. Meysey-Thompson referred to the controversy as to the relative advantages of hydraulic and electric machinery for docks, and said that probably all light and fast-working machinery, with the exception of capstans which are only worked intermittently, was better operated by electricity. For all underground machinery, excepting capstans which are constantly employed, and all heavy appliances of a quick-working character, hydraulic power was more efficient. Until quite recently the hydraulic accumulator was operated by a steam engine working high-pressure pumps, but electrically-driven pumps are being substituted with advantage. On large docks the demands on the accumulator are constantly varying, and a few weeks ago he had timed an electrically-driven accumulator and ascertained that it started and stopped pumps of 130 horsepower thirteen times in ten minutes. As the service required that the pumps should not run more than ten seconds before delivering water after starting the motor, there must be considerable stress on the machinery in absorbing the momentum of a falling accumulator, and so frequently changing its direction. Several systems of electrical control gear to start against full load have been introduced, and most of these employ a small subsidiary motor of about one-half horsepower, controlled by the position of the accumulator, and so geared to the starter as gradually to cut out the resistances in the rotor circuit at starting. The author described a method which avoids the use of the subsidiary motor and electrical connections to the accumulator and has the advantage of enabling the main motor, of whatever power, to start under practically no load. The accumulator operates a small pilot hydraulic valve which controls both the electrical starter of the motor and a by-pass on the pump. At starting the operation is first to accelerate the motor gradually under no load by cutting out the resistances until full speed is attained, and afterward to bring on full load slowly by closing the by-pass on the pump. When stopping the by-pass is first opened, the load on the motor reduced, and then the electrical starter breaks the circuit. By this system both the electrical starter and the by-pass work in consonance, and in emergency the former can be cut out and the pump worked directly by the accumulator.—*Times Engineering Supplement (London), November 11.*

ALTERNATING CURRENTS AND THEIR APPLICATIONS.

BY EDSON R. WOLCOTT.

CHAPTER I. (PART IX).—CAPACITY AND INDUCTANCE.

ELECTROSTATIC INDUCTION.

Heretofore the electric current has been considered to the exclusion of the static charge. However, the latter is of considerable importance in alternating currents, especially where long transmission lines are used. As is well known, static charges of electricity, produced by rubbing glass with silk, or sealing wax with flannel, can be accumulated by means of electrical devices called condensers. A condenser consists essentially of two or more electrically conducting plates separated by an insulator, as shown in Fig. 29, where A and B represent two plates and X represents the insulator. If a positive charge, such as would be obtained by rubbing a glass rod with silk, be given to the conductor A, an equal quantity of negative electricity accumulates on B. This action is known as electrostatic induction as distinguished from electromagnetic induction, previously explained. It is the induction of electric charges and not currents. To be sure, these charges, being electricity at rest, become currents when suitably connected to conductors. For example, if the two sides A and B of the condenser illustrated in Fig. 29 be connected, the two charges neutralize each other.

THE CONDENSER.

A condenser usually consists of many layers of conducting and insulating material alternately arranged. Every other conducting plate is connected to one terminal and the intervening conductors to the other terminal.

The capacity of a condenser increases with increasing the area of the plates and with decreasing the distance between them. It also depends on the material of the insulator between the conductors; for example, being greater when glass is used than when only air intervenes, and still greater if mica is used to separate the plates. The unit of capacity is called the "farad," but this is so large that its one-millionth part, or the "microfarad," is the unit in common use.

A conventionalized condenser composed of a number of plates is illustrated in Fig. 30. This is made of many layers of mica and tinfoil.

EXAMPLES OF CAPACITY.

A telegraph, telephone or transmission line is a type of condenser, as is, indeed, every arrangement containing conductors separated by insulators. In the case of a conducting wire suspended on poles, the

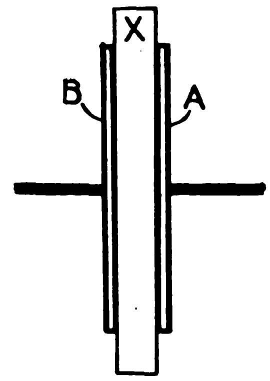


FIG. 29.—SIMPLE CONDENSER. A. B—CONDUCTING PLATES. X—INSULATOR OR DIELECTRIC.

wire itself forms one conductor and the earth the other plate of the condenser, the air between acting as the insulating medium. In the case of ocean cables the wire within acts as one conductor, the water as the other, and the insulation of the cable forms the insulating medium between. The capacity present in long ocean cables was one of the serious difficulties of their early operation, and its effects are by no means entirely eliminated at the present time.

CONDENSERS IN ALTERNATING-CURRENT CIRCUITS.

The electric charge produced by friction and electrostatic machines is of very high voltage, but is relatively small in amount. However, since the quantity of electricity accumulated by a condenser increases with the voltage, even with a

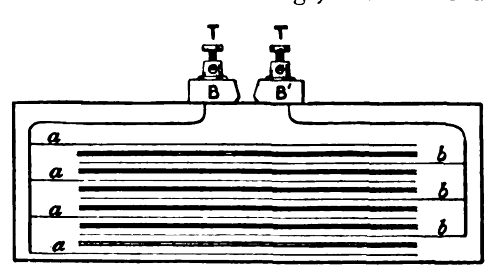

FIG. 30.—CONDENSER, ORDINARY TYPE (SECTION).

condenser of small capacity, considerable quantity may be stored up when a very high voltage is used. When a condenser is connected to an alternator each time the current changes direction the condenser charges and discharges. Thus an alternating current will flow in a circuit containing an alternator and a condenser, though with ordinary condensers the current is small. This is more clearly shown in Fig. 31.

Suppose at one instant of time the positive side of the generator is connected to A and the negative to D, a positive charge flows in AB in the direction of the arrow, producing the charges as shown in the condenser C. An equal positive charge is repelled along DE in the direction of the arrow. When the current changes direction the same phenomenon takes place except in the opposite direction. The negative charge could also be used to explain the above, as it may be assumed that a current of electricity consists of the flow of positive charge in one direction and a simultaneous negative charge in the other.

The effect of a condenser in an alternating-current circuit is such as to introduce another induced electromotive force, namely, that of the charge in the condenser and the characteristics of this are such that it tends to annul the induced electromotive force previously described, due to the changing magnetic field.

BALANCE OF INDUCTANCE BY CAPACITY.

In other words, the increased opposition to the flow of an electric current

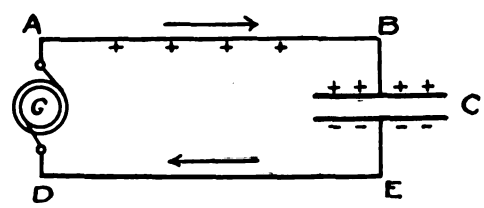

FIG. 31.—CONDENSER IN ALTERNATING-CURRENT CIRCUIT.

produced by the introduction of inductance in the circuit can be annulled by the introduction of suitable capacity in the same circuit. Suppose, for example, that a coil having a resistance of ten ohms and an inductance of 0.01042 henry be introduced into an alternating-current circuit having a frequency, f, of 127.5 cycles (these numbers are chosen so as to make the product $2\pi f = 800$, which is convenient to handle). In order to obtain a current of ten amperes in such a circuit an electromotive force of 130 volts will have to be applied, as shown in Fig. 32, where AC equals 100 volts, the product of the current by the resistance, and $BC = 2\pi fLI = 800 \times .01402 \times 10 = 83.3$ volts, the drop in potential over the coil. AB equals the resultant, or 130 volts, and is the voltage necessary to obtain a current of ten amperes. It may be obtained graphically. Thus, if AC = 100 units and BC = 83.3 units, then AB = 130 units, or $\overline{AB}^2 = \overline{AC}^2 + \overline{BC}^2$.

Suppose now that a capacity of 150

microfarads be introduced into the same circuit, as is shown in Fig. 33. Here G represents the alternating-current generator, L the coil and C the condenser. With the frequency, capacity and inductance as stated above, the last two balance each other exactly, and 100 volts applied at G gives just ten amperes. This is the same value that would be obtained if there were no inductance or capacity in the circuit. In other words, the potential drop over the condenser just balances that over the coil. Graphically this is represented by Fig. 34, where BC represents the potential drop over the coil and CD represents that over the condenser; the two differ 180 degrees in phase, or are exactly opposite in direction.

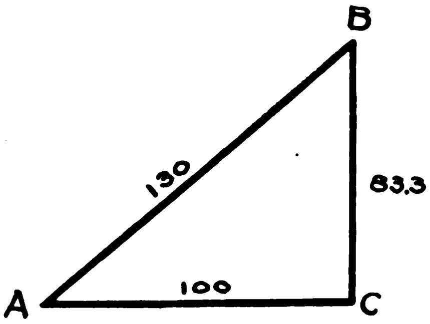

FIG. 32.—COMBINATION OF ELECTROMOTIVE FORCES.

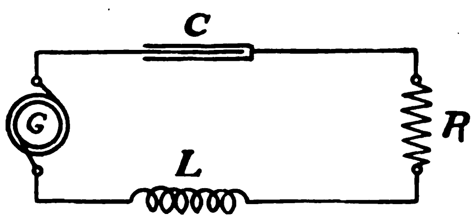

FIG. 33.—CAPACITY, RESISTANCE AND INDUCTANCE IN ALTERNATING-CURRENT CIRCUIT.

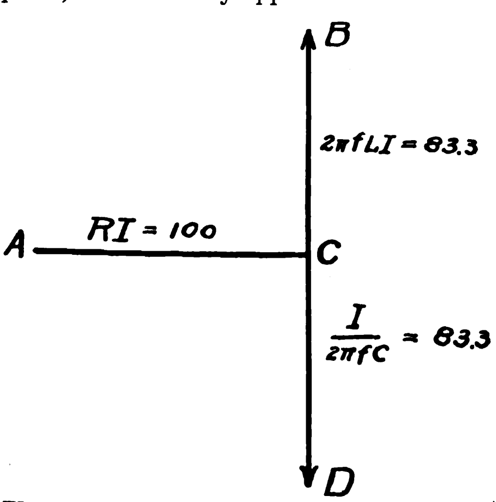

FIG. 34.—RELATION OF ELECTROMOTIVE FORCES FOR CONDITIONS OF RESONANCE.

The opposition offered by a condenser to the flow of an alternating current is inversely proportional to the capacity, for the greater the capacity the less the opposition; while with a coil, the greater the inductance, the greater the opposition. The capacity reactance of a circuit containing a condenser is therefore determined as $\frac{1}{2\pi fC}$, where C is calculated in farads. Thus 150 microfarads = .00015 farad.

$$\frac{1}{2\pi fC} = \frac{1}{800 \times .00015} = \frac{1}{.120} = 8.33$$

and the potential drop $10 \times 8.33 = 83.3$. This can be expressed algebraically as follows:

$$Z = \sqrt{R^2 + \left(2\pi f L - \frac{1}{2\pi f C}\right)^2}$$

where Z represents the impedance of a circuit containing both inductance and capacity.

ALTERNATING-CURRENT CURVES.

It has been assumed thus far in this discussion that the alternating-current curves are of the sine form first shown, but this is not always the case in actual practice. A very common wave form is that illustrated in Fig. 35, which was observed with an oscillograph, an instrument especially designed for this purpose, which will be described later. The fluctuations shown in this electromotive-force curve are due to the armature windings being placed in slots. The effect of inductance on this curve is to smooth it out, as shown in Fig. 36. Inductance in an electrical circuit acts like inertia in masses and tends to prevent sudden changes. Current through a condenser, on the other hand, magnifies the irregularities in the voltage curve, for any change in the electromotive force produces a rush of current into or out of the condenser. This is illustrated in Fig. 37, which represents the current produced by the voltage wave shown in Fig. 35 when applied to a circuit containing a condenser. A condenser resembles in some ways an elastic medium, in that slight vibrations may cause large disturbances. This is particularly true when the vibrations are accurately timed. For example, the trotting of a horse across a bridge has been known to set the bridge to vibrating to such an extent as to cause serious damage.

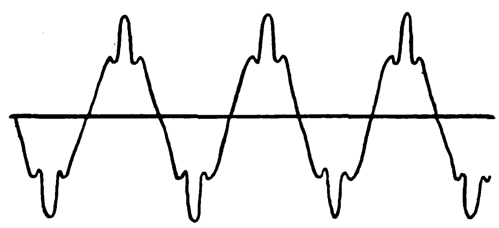

FIG. 35. — OSCILLOGRAM OF VOLTAGE WAVE FROM ALTERNATOR HAVING ARMATURE CONDUCTORS ASSEMBLED IN SLOTS.

The application of the phenomenon of balancing capacity by inductance is now being worked out to remedy the defects of long-distance telephones, telegraph and submarine cables. The capacity of the last particularly is very great, and inductances, called "loading coils," are being introduced at certain distances to annul the condenser action.

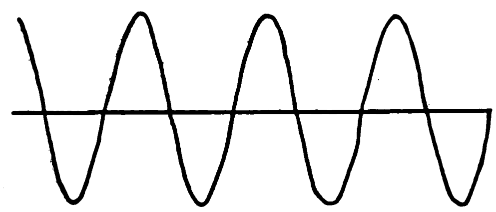

FIG. 36. — OSCILLOGRAM OF CURRENT CURVE PRODUCED BY SAME VOLTAGE WAVE IN CIRCUIT CONTAINING INDUCTANCE.

TUNING ELECTRICAL CIRCUITS.

The proper adjustment of capacity and inductance for a given frequency finds many applications where currents of very high frequency are used, such as in wireless telegraphy and other forms of high-tension discharge. The proper regulation of the value of condensers and the inductances is often called tuning from its resemblance to the tone adjustment of musical instruments. The phenomena observed in electrical tuned circuits are of very great interest, but rather too complicated to be considered here.

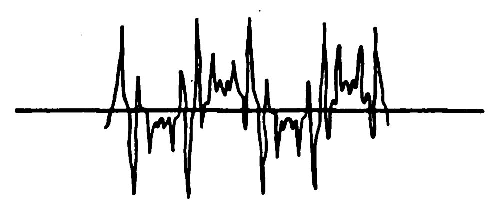

FIG. 37. — OSCILLOGRAM OF CURRENT CURVE PRODUCED BY SAME VOLTAGE WAVE IN CIRCUIT CONTAINING CAPACITY.

Northwestern Elevated.

John B. Dennis, of Blair & Company, has completed a plan for readjusting the Northwestern Elevated finances, including the issue of first-mortgage bonds at four and one-half or five per cent to take up the entire four per cent issue and possibly the new issue of preferred stock. The floating debt will be liquidated and provision made for development.

The first installment of electrical machinery for the Gatun handling plant for the Panama Canal has arrived on the Isthmus. It is expected that the plant will be in operation by July 1, 1909.

Cincinnati to Have an Electrical Show.

To show that it is wide-awake to the progress and rapid strides of the electrical industry, Cincinnati has planned an electrical show for next spring. The city has marked advantages of an industrial and commercial character, owing to its nearness to the sources of supply of the principal raw materials, its good transportation facilites and central location. These factors have created a demand for an exposition which will familiarize the general public with the practical applications of electricity. With this object in view the Western-Southern Electrical Show has been announced for the two weeks, March 13 to 27, 1909. About thirty per cent of the space has already been subscribed for and the success of the show is assured.

The representative character of this exposition is indicated by the personnel and standing of its directorate, among whom are: John L. Shuff; A. F. Chamberlain and J. A. Brett, Westinghouse Electric and Manufacturing Company; F. D. Lawrence, F. D. Lawrence Electric Company; J. D. Lyon; A. J. Conroy; M. E. Moch; Samuel Glover, Post-Glover Electric Company; J. E. Devere, Devere Electric Company; L. J. Van Lahr, Provident Savings Bank and Trust Company; L. J. Lowenberg, Reliance Engineering Company, and General Michael Ryan.

Alton Road Begins Motor-Car Experiments.

Officials of the Chicago & Alton Railroad have started on a demonstrating trip of the new Strang motor car. The experiments will continue for a period of three weeks. The method of propulsion of the car is electricity generated by a gasoline engine. The system consists of a gas engine with direct-connected generator, electric transmission and control between the generator and truck motors and a storage battery. By means of a starting rheostat the current is taken from the battery to the generator, which is converted temporarily into a motor for starting the engine. The fuel and ignition then being turned in, the engine and generator increase in speed to a point where the generator, acting as such, produces an electric current. When the car is standing still the current will go into the storage battery and be kept in reserve until such time as the motors require more current than is produced by the generator. The engine occupies the forward end of the car and the balance of interior space is devoted to a passenger compartment. The railroad is experimenting with the car both from the standpoint of economy and improvement in service between stations on branch lines.

The London Electric-Power Problem—Bulk-Supply Scheme Rejected.

After a hearing lasting fifteen days a committee of the House of Commons has rejected the bill which proposed the erection of a generating station having a capacity of 120,000 kilowatts to supply electrical energy in bulk to London and a large surrounding area. This decision is of much greater moment than may actually appear on the surface, for it is the application of a policy which if prosecuted to the fullest extent means the stifling of private enterprises in London, at any rate while the present Government is in power. The rejection of this electric supply scheme is undoubtedly a political decision, and one cannot help recalling the fact that for no less than thirty days a most influential committee of the House of Lords considered the same scheme in much greater detail than did the House of Commons and finally passed it in a somewhat modified form. The House of Lords committee included Lord Cromer, who was in charge of the administration of Egypt for so many years, and Lord Welby of financial fame, for many years chairman of the finance committee of the London County Council. But the House of Commons committee, presided over by a coroner, by the way, and consisting of members with no experience in large commercial undertakings or problems, has the final word in this particular instance, and so the scheme is dead. It is interesting to note the conflict of opinions between the political party which has undoubtedly wrecked the scheme and the actual opponents before the committee. On the one hand it is argued that such a scheme is wanted, but that it should be in the hands of the London County Council, and on the other hand it was urged that the present supply is ample for all purposes and that no bulk scheme is required.

This brings us back to the present position. Broadly, London has been parcelled out, for electric supply purposes, to a number of local authorities and companies. The latter hold their powers in perpetuity, while the latter are purchasable in 1931 by the local authorities of their respective districts. No local authority, however, may purchase anything outside its area, and knowing this limitation the companies have in many cases carefully set to work and erected generating stations outside the boundary, with the result that many a local authority is in the position of being able to purchase only the distributing mains. At the commencement of the present session of Parliament the companies brought in a bill giving them powers to link up the various generating stations so as to be able to use them with greater economy. A wise legislature in 1882 had put upon the companies the provision that they should not "associate," an absurd position of affairs which has remained in force ever since. As a *quid pro quo* for granting these powers the Government expressed its intention of inserting a clause in the bill substituting the London County Council the purchasing authority in respect of all the companies instead of the individual local authorities, and this would to a large extent get over most of the difficulties applying to the local authorities purchasing. For instance, practically one undertaking would then be in existence on the one hand. When the matter came before the same committee which rejected the bulk scheme, it was quickly realized that difficulties lay in the way. While on the one hand the London County Council had been constituted the purchasing authority for all the companies in 1931, it was suddenly discovered that certain local authorities had special powers of purchase at dates preceding this, and as the committee refused to take away these special powers the companies threatened to withdraw the bill. Having gone so far, however, the committee refused to allow this to be done, and what Parliament is pleased to call a comprehensive scheme is one over which some local authorities have purchasing powers before 1931, as to a portion, and the London County Council purchasing powers over the remainder after 1931. Furthermore, no provision is made for merging the undertakings of the local authorities into the larger undertaking when the County Council comes into possession, and unless some such arrangements are made the year 1931 will witness the London County Council in several portions of London competing with a small local authority electricity undertaking, and both the County Council and the local Borough Council will be representing the same ratepayers! Confusion is certainly becoming worse confounded the further the matter goes. A. W.

AN ENGLISH VIEW OF SOME TRACTION PROBLEMS.[1]

BY H. E. YERBURY.

Ordinary street traction has during the past ten years become standardized and improvements which have been made in electrical and mechanical details are of a minor character.

Series-parallel control with series motors appears to have fulfilled all reasonable requirements, and although the all-around efficiency may be improved in many cases, yet as long as the motors run without vigorous sparking and the cars maintain schedule speed, and the temperature of motors and bearings is not abnormal, and the cost of maintenance is fairly low, the average tramway manager is satisfied.

In respect to the economical generation of electricity, we can hardly expect—with the present price of fuel—that costs will be materially reduced, for about fifty-two per cent of the total generating costs are now expended in coal. Engineers of combined lighting and power stations should consider themselves fortunate in being able to obtain such a high price for current supplied to tramway undertakings, for the average price charged in Great Britain is 2.82 cents per unit, whereas in tramway power stations current can be generated and distributed at about 0.78 cent per unit, and including interest on capital, sinking fund, rates, taxes, insurance, etc., at a total cost of about 1.32 cents per unit. We may therefore reasonably expect in the near future to see a reduction in price to large consumers, such as tramway departments.

As what might be called commercial rather than technical knowledge often governs tramway administration and management, such considerations as the determination of the characteristic properties of tramway motors for the work they are often called upon to perform, and the plotting of efficiency curves of motors in order to get the greatest commercial advantage in working cars, are often ignored, and if drivers could be educated to work controllers and brakes in an efficient manner and utilize the kinetic energy, the resultant saving would, in the author's opinion, be at least equal to the results obtained by regenerative control, which, by the way, does not appear to have made the progress that was expected at the time of its inception, for it is evident, after comparing the relative efficiencies and advantages of series and shunt motors for traction work, that there is nothing to be gained by using shunt motors.

It speaks well for the stability of series motors when one finds that notwithstanding the diameter of carwheels has been increased two to three inches, canopy tops have been fitted, making cars some two tons heavier, and motors are now often used for ordinary service braking; yet the same motors which were designed for lighter work are well able to stand these onerous conditions. But we must expect that maintenance costs will increase, and in the author's opinion it will doubtless be necessary in the near future to install ventilated motors, possibly of the interpole type, to effectively meet the requirements of modern practice.

The trackless trolley system, which has for several years been in operation on the Continent with a fair measure of success, appears to offer advantages in the way of low capital and running costs, and the system generally compares very favorably with motor cars carrying their own power equipment. In the author's opinion there is a useful and remunerative field for a trackless trolley system in many districts, as the same overhead equipment could be retained if the population or requirements of a particular district justified the laying down of rails with a frequent service of cars after, say, a few years' running under above conditions.

In the early days of railway electrification three-phase motors were used, presumably for want of a better system, for it was then necessary to run two overhead wires for each track, yet this was proved to be more economical than laying heavy insulated steel rails on the permanent way as required for locomotives working with continuous current.

Now that single-phase motors are built that have the characteristics and large starting torque necessary for railway work, we may expect to see rapid progress in that direction. It has been demonstrated in many instances that, as a single-phase motor is nothing more than a direct-current motor with laminated fields so as to reduce the iron losses with alternating-current excitation, and fitted with a compensating winding for neutralizing armature action, these motors may be used for either system, and in the author's opinion should prove very useful for tramway and railway work in this country, for when run on a direct-current system, say for town or suburban service, the motors would have an efficiency of about eighty-eight per cent, and for linking up towns or cities the same cars and motors may be used with, say, a twenty-five-cycle single-phase current and give an efficiency of about eighty-three per cent. In such cases the single-phase system is economical, as energy can be transmitted at high voltage, and the capital and maintenance costs are low.

A problem which is engaging the minds of designers at the present time is that of building satisfactory direct-current turbo-generators of, say, 1,000 to 1,500-kilowatt capacity. With alternators no difficulties present themselves, for they can be readily designed suitable for the high speed required by turbine manufacturers, whereas for the comparatively low speed required up to the present for direct-current generators, steam consumption is invariably higher, and is brought down to a point practically equal to the steam consumption of reciprocating engines of equal power. Important developments and improvements have been effected within the past few years, and we now find that compensating windings and interpoles have been adopted for neutralizing reactance voltage and armature reaction, and radial commutators appear to have given good results, so that we may reasonably expect that brush and commutator troubles, with their high maintenance costs, will be minimized, and that carbon brushes will be universally adopted in the future. I think we may also expect to see great improvements in the general design and mechanical construction of turbines. It is well known that clearances in the past have been so fine and so closely calculated for a predetermined temperature of steam that either serious trouble or loss in efficiency has taken place when the temperature of steam has been raised or lowered, and to overcome this trouble combination turbines of impulse and ordinary blading design have been evolved. The true value of the latent heat of steam is now being fully understood and appreciated, and we may reasonably expect that turbines will be so designed in future that their efficiency will not be impaired by eliminating the very fine clearances which have been the primary cause of considerable trouble in the past.

[1]Abstracts from an inaugural address by the chairman of the Leeds local section of the Institution of Electrical Engineers, delivered at the University of Leeds, England, on October 28.

PRACTICAL CONSIDERATIONS IN THE SELECTION OF TURBO-ALTERNATORS.[1]

BY M. KLOSS.

Whenever a new invention is brought out, its development is to a certain extent retarded by the fact that people base their judgment of the new thing on their experience with old things, or, in other words, they measure it with the same scale they are accustomed to use without first considering whether this attitude is fair toward the new thing. It seems to me, therefore, the duty of all who take an active part in its development, to show that the supposed discrepancies are chiefly due to using the wrong scale, to provide the right scale instead, and to show the proper point of view from which the new thing ought to be looked at.

These considerations have often occurred to me when designing turbo-alternators, especially when reading specifications for such machines. Very often one finds conditions laid down in a specification which are simply copied from slow-speed alternators, where they are quite within the limits of commercial or physical possibilities, whereas, in the case of turbo-alternators, they may be impossible of fulfillment, owing either to mechanical reasons or to commercial considerations.

I, therefore, regard it advisable to investigate some of these points from a designer's point of view for the guidance of those who have to get out specifications for a turbo plant. This is the more important at the present juncture, as the various makers have now gained a more or less costly experience in manufacturing this new class of machinery, while, on the other hand, the demand for larger high-speed units is constantly increasing.

The three points with which I propose to deal in this paper are: Ventilation, voltage regulation, power-factor and its influence on the size of machine.

VENTILATION.

In old times (relatively to the electrical industry), nobody troubled themselves about the heat produced by a dynamo in the form of losses. However, when competition became keener and the theory of the design was better understood, the makers were driven to squeeze as much output out of their machines as they possibly could. The limit was then given by the heating of the machine. Now designers are not satisfied even when they have found out how to predetermine the heating under given conditions, but they are carefully studying the laws of ventilation with a view to improving this through proper design, or even by providing special means for insuring the most efficient method of cooling a machine.

It is well known that under otherwise equal conditions the output of an electrical apparatus increases approximately

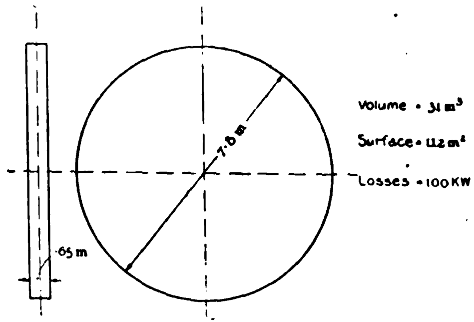

FIG. 1.—OVER-ALL DIMENSION OF LOW-SPEED MACHINE.

in proportion to its volume, or as the cube of its linear, while the radiating surface only increases as the square of dimensions. Hence there must be a limit of size where the surface is no longer sufficient to radiate the heat produced in the apparatus. This is the reason, for instance, why transformers above a certain output can only be built with artificial ventilation. As regards machines with moving parts we are much better off, because they produce, through their own motion, a natural ventilation, which helps to keep the machine cool.

The time is not far distant when we shall have to regard a scheme of ventilation for a turbo-alternator of large ca-

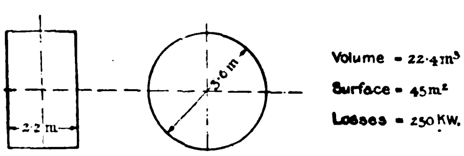

FIG. 2.—OVER-ALL DIMENSION OF HIGH-SPEED MACHINE.

pacity as a natural and essential part of the plant, just as one does the condensing plant for the steam portion. In order to make this quite clear, I give in Figs. 1 and 2 the overall dimensions of a slow-speed alternator for 2,000 kilowatts and for a turbo-alternator for 6,000 kilowatts. The total losses in the low-speed machine are about 100 kilowatts. However, the losses in the higher-speed machine are about 250 kilowatts, or two and one-half times as great as in the other machine. For every 100 kilowatt losses, therefore, there is only a volume of nine cubic meters available against thirty-one cubic meters in the large machine (that is, less than one-third), and the available surface is only eighteen square meters per 100 kilowatts against 112 square meters in the first machine (that is, less than one-sixth). I think these figures show clearly that it is quite necessary for the designer to provide special means for dissipating the heat which is generated in a relatively very small space. This is the more important, as the high peripheral speed at which modern turbo-alternators run is liable to produce noise, and in order to reduce this as much as possible one is bound to enclose the whole machine. The result is that the conditions of cooling by simple radiation and conduction to the surrounding air are made still worse.

The consequence of this is that makers must design the rotors so that, either by their own shape or by additional fans at their ends, they produce a strong draft through the machine. This seems to be now quite common practice, at all events with machines, say, up to about 3,000 kilowatts.

If, however, sets of larger capacity are to be installed, the user has to face the fact that rather large quantities of heat will be produced in a comparatively small space, and it is quite a serious problem to consider beforehand what he is going to do with this energy. For instance, in a power station where it is intended to install six turbo sets of 6,000 kilowatts each, the amount of heat produced by these six sets running at the same time will be something like 1,500 kilowatts, without allowing for the heat radiated by the steam turbines. If this great amount of energy were allowed to go into the engine room without special provision for dispersing it, it would not be surprising to find the temperature in the engine room rising rather rapidly to a point which would make it impossible for men to stay in the room.

The heat created in the room can escape only in two different ways: A portion will be conducted and radiated by the walls, the roof, and the floor; and another portion will disappear by the natural renewal of the air through windows and doors. If these two means are not sufficient, special arrangements must be made for ventilating the room.

Now, if the amount of heat passing through the walls is calculated, it will be found that this is comparatively small.

[1] Abstract of a paper read before the Manchester Local Section of the (British) Institution of Electrical Engineers.

For instance, I have assumed that a house of very ample size would be provided for the 6,000-kilowatt alternator mentioned before, and I have calculated how much heat would be conducted and radiated by walls, roof and floor. Assuming an outside temperature of 25° C. (= 77° F.) and a room temperature of 34° C. (= 93° F.) corresponding to conditions of a hot summer day in England, I find that this quantity of radiated heat only amounts to about 15 kilowatts, which is practically nothing compared with the total loss of 250 kilowatts.

Now, when it is admitted that special ventilation must be provided for the power house if large units are to be installed, it seems to me to be somewhat unreasonable, first, to let this quantity of heat enter the engine room (making it very uncomfortable to stay there), and afterward to adopt means to drive it out again and replace it continuously by air taken from outside. I rather think the idea must offer itself to the user that the best and easiest way would be not to let the hot air issuing from the machine enter the engine room at all, but to take it straight away from the machine to the outside through special ducts. A further consideration leads to the conclusion that it is also very advantageous for the cooling of the machine not to use the engine-room air as a cooling medium (as it is already warm to begin with), but to take the necessary cooling air direct from the outside atmosphere. This arrangement also enables the cooling air to be cleaned by passing it through a filter, thus avoiding dirt and moisture from getting into the machine.

But it is not only for the sake of convenience that, instead of ventilating the engine room, the machines should be ventilated directly. It is also very advisable to do this from the point of view of saving capital and running costs. This may best be explained by carrying out a comparative calculation of the amount of air required for cooling by the two different methods. If we provide a special ventilation scheme for the machine itself, we can, of course, allow the air to rise to a higher temperature, because it does not pass into the engine room. Calculations show clearly that by providing a ventilation scheme as part of the machine plant instead of part of the building plant, a saving in capital outlay and running cost might be effected.

In conclusion, I should like to enumerate again the chief advantages of this system:

1. The machine is cooled with fresh, clean air, free from dirt and moisture, and therefore has a lower temperature rise than if the ventilating air was taken from inside the power house.

2. The machine is fully enclosed, and by this means the noise is reduced to a minimum.

3. The appearance of the machine is greatly improved.

4. The hot air issuing from the machine does not enter the engine room, so that it is quite easy to keep this at a moderate temperature.

5. The capital outlay for the necessary ventilating plant is smaller if the machines themselves are ventilated than if the engine room is specially ventilated.

6. In addition to this, it is quite possible to utilize the energy contained in the hot air. It could be used either for heating buildings, or heating feed water for boilers, or by blowing it into the boiler fires, or for all kinds of other useful purposes, so that one may regain part of the energy which would otherwise be lost entirely.

I am quite aware that there are at present different ideas as to whether or not such a ventilation scheme is to be recommended. But I am convinced that the final decision cannot be influenced by ideas, but only by facts.

The object of my statements is not so much to advocate one particular scheme of ventilation as the best. What I am aiming at is to impress upon people connected with the laying out of power stations for large high-speed units the great importance of not neglecting the ventilation problem. Careful calculations should always be made in this respect. The amount of heat produced is to be calculated, and then the architect of the building has to state how much heat will, under certain given conditions of outside and inside temperature, be radiated by the walls and the roof, and how much can be got rid of by the natural ventilation through windows and doors. The calculations will show that these two quantities represent only a very small percentage of the total amount of heat produced, and that therefore by far the greatest amount of that heat must be dealt with by special ventilating arrangements.

VOLTAGE REGULATION.

In order to build a machine which can give the greatest possible output at a minimum cost of manufacturing, we must get as much flux through the machine as possible, and provide the highest possible number of ampere-turns on the armature or stator, because at a certain given speed the output is proportional to these two quantities. Now, the number of ampere-turns determines the armature reaction, and in order to balance this under normal running conditions, and to keep the voltage regulation within reasonable limits, we have to provide a sufficiently high number of ampere-turns on the field, or, in other well-known terms, we must design the machine with a short-circuit current which is sufficiently high, compared with the normal current. With the ordinary slow-speed alternators, it has become quite a usual practice to design the machines such that with no-load excitation the short-circuit current is equal to about two and one-half to three times the normal current. This means that the number of excitation ampere-turns even for no load must be two and one-half to three times as great as the full-load ampere-turns on the armature. The amount of copper therefore to be provided on the field must be correspondingly greater than the copper in the stator.

In large multipolar alternators there is no difficulty in doing this, because there is plenty of space left between the poles for the field winding, on account of the very small angle formed by two adjacent poles. For our investigation we are only interested in the number of ampere-turns per centimetre pole-pitch. In order to arrive at an idea of the comparative amount of ampere-turns per centimetre pole-pitch, we have only to compare the useful winding space available in, say, a six-pole and a sixty-pole alternator. The ratio of the two available areas is, of course, not equal to the ratio of possible ampere-turns per centimetre pole-pitch, because the current density may be different in the two machines. Still, with due allowance for this difference, we can get an approximate idea of the actual conditions by simply comparing the useful winding space. Figures show that in the case of the six-pole turbo there is only about one-quarter of that winding space available which can be made use of in the sixty-pole slow-speed alternator.

It is therefore evident that we shall not find the slightest difficulty in the latter case to provide for a large number of ampere-turns and still keep the field quite cool. Or, in other words, we can easily design a slow-sped alternator with a high short-circuit current, and consequently with a good voltage regulation, without being restricted by the heat limit of the field. The output of the generator will be more limited by the magnetic densities than by the armature strength (number of ampere-bars per centimetre circumference).

In the six-pole turbo it is clear that we must come up against the heat limit of the field, on account of the rather restricted winding space, and I think every designer of turbo-alternators will agree that the output of such a machine is never limited by the stator, but always by the rotor, whether this may be of the salient pole or of the cylindrical type.

In designing a machine which should be salable as regards price, one is bound to go to the heat limit of the rotor. But even then, for the simple geometrical reasons given, it will not be possible to obtain the same number of ampere-bars per centimetre as in a multipolar machine. Consequently the armature strength must also be reduced, which means a reduction in the output per centimetre circumference, with a corresponding increase in price per unit of output. Now, in order to prevent this increase in unit price from becoming prohibitive, we are driven to design the machine with a comparatively lower short-circuit current, because then we need not reduce the armature ampere-turns per centimetre in the same ratio as we are bound to do with the field ampere-turns. This, of course, results in sacrificing something of the regulation of the machine, and it is this point which I want to make quite clear to those who have to draft specifications for turbo-alternators. One should always bear in mind that it is not possible to obtain the same regulation figures with a turbo as with an ordinary multipolar slow-speed machine. When I say "it is not possible," I do not mean, of course, "physically impossible," but impossible from a "commercial" point of view, because the regulation of any given machine is only a question of rating, and therefore a low regulation can only be obtained by an increase of price per unit of output. However, it seems rather doubtful whether any station engineer or any corporation would be willing to pay a considerable excess of money in order to get a machine with the same voltage regulation as can without difficulty be obtained with a multipolar alternator.

Now, having outlined the reasons for the difference in the conditions of voltage regulation in the two classes of machines, I will go more into details and show some curves, which will give an idea of the quantitative difference in the two machines.

Fig. 3 represents a typical open-circuit characteristic which I have used as a basis for all further investigations. For the sake of comparison, I have chosen the scale so that I call the normal voltage 100 per cent, and also the corresponding no-load excitation 100 per cent. At this excitation the machine will have a certain definite value of short-circuit current I_k, while the normal current of the machine is I_n at a certain power-factor $= \cos \phi$, and we will measure the current, not in amperes, but simply by the ratio of its value to the short-circuit current, that is to say, $\frac{I_n}{I_k}$. This factor will therefore give the rating of the machine corresponding to its kilovolt-ampere output, on which the size of it will depend. For

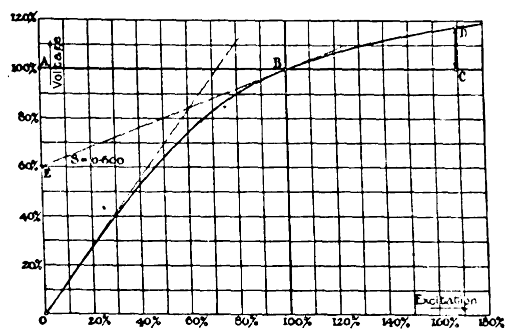

FIG. 3.—TYPICAL OPEN-CIRCUIT CHARACTERISTIC.

the station engineer, however, the kilowatt output of his machine is the more important quantity, and in order to introduce this into the comparative investigation we will call the watt component of the current I_w, which will, of course, be $= I_n \cos \phi$, and therefore the kilowatt output of the generator can be expressed by the ratio $\frac{I_w}{I_k}$.

If we now want to find the full-load excitation, we have to allow an increase in excitation due to three different factors: First, the increase in flux through the gap due to the armature leakage; secondly, the necessary ampere-turns to counterbalance the armature reaction; and thirdly, the increased pole leakage. Thus, we obtain a full-load excitation, represented by point C in Fig. 3. If the load is taken off at constant excitation and constant speed, the open-circuit voltage will then be given by point D, and therefore the distance CD represents the rise in voltage for inductive full load, and this is the quantity which the designer has to keep within a certain limit, in accordance with the specification he has to work to. The value of CD, however, does not solely depend on the distance BC, and therefore on the three factors mentioned above; but it is to a large extent also determined by a fourth factor, namely, by the shape of the open-circuit curve. It is evident that with the same excitation AC, a machine with a flat characteristic will have a smaller voltage rise than a machine with a steep open-circuit curve. As the shape of this curve depends on the saturation of the magnetic circuit, we must find a way to signify the degree of saturation prevailing in a machine. The simplest way to do this is to introduce the slope of the curve at the point of normal voltage. For this purpose we will draw a tangent to the curve at the point B, which will cut the ordinate axis at a point E. It is clear that this point E will be higher the greater the saturation is. We will therefore call the factor $S = \frac{OE}{OA}$ the "saturation factor" of the machine. In the case of Fig. 6 we find $S = 0.600$.

We now can say that the voltage rise depends on the following four factors:

1. Armature leakage.
2. Armature reaction.

} Proportional to load current.

3. Increase of pole leakage.
4. Saturation factor.

} Partly influenced by saturation factor.

If a special machine is designed to meet a certain specification, then the designer can choose to a certain extent the value of factor No. 3, by so fixing the dimensions of the magnetic path that he obtains the most suitable initial pole leakage at no load to meet the conditions of specification. In most cases, however, the designer will, from a manufacturing point of view, avoid special designs, and will want to put forward standard machines. In such cases he is more or less tied down to a certain initial pole leakage, and if he has to fulfill certain conditions of voltage regulation, he can only do this by choosing suitable values for the quantities given under Nos. 1, 2 and 4.

This is the reason why I have restricted myself in the following to an investigation of the influence on voltage rise, of the rated load current, and the saturation factor. The two variable quantities for this investigation will therefore be the ratio $\frac{I_n}{I_k}$ or $\frac{I_w}{I_k}$, and the factor S. The calculations have been carried out for various power-factors, namely, $\cos\phi = 1$, 0.95, 0.90, 0.80, 0.70 and zero, and have in most cases been extended over a range of $\frac{I_n}{I_k} = 0$ to $\frac{I_n}{I_k} = 1$, and a large number of curves have been plotted for the different conditions.

These curves show clearly that it is advisable to work at relatively high saturation, especially in the case of machines which are to be designed for a relatively low short-circuit current, that is to say, for a high ratio of $\frac{I_w}{I_k}$, whereas in machines with a high short-circuit current the saturation factor has not so great an influence on the regulation. However, as the high increase of exciting current at high saturation is not desirable, one is obliged to work at lower saturations than one would do if only the voltage regulation had to be looked out for. We must therefore make a compromise, and from my experience I find that for a modern machine the saturation factor should be between 0.50 and 0.60. The values of rise corresponding to these two values of saturation factor have been plotted against the power-factor in Fig. 4.

We find that for geometrical and physical reasons one is bound to work a turbo at a higher value of $\frac{I_w}{I_k}$ than is possible with a multipolar. As fair average figures we can assume $\frac{I_w}{I_k} = 0.50$ for a turbo, and $\frac{I_w}{I_k} = 0.30$ for a slow-speed machine. The two pairs of curves given in Fig. 4 can therefore be taken as representing relative conditions in the two classes of machines.

From what I have said before it is evident that the price will be affected by the specified figure for voltage regulation. A machine with small regulation is bound to be more expensive than one with a larger regulation figure. In order to make a comparison, I have not worked out a new design for every different condition, but have simply modified the rating of a standard size, so as to fulfill various conditions of regulation, the price remaining constant for that machine.

Let us assume that a standard three-phase machine gives 1,000 kilowatts at $\cos\phi = 0.80$, 100 amperes normal current, $I_w = 80$ amperes watt current (or current at unity power-factor), the no-load excitation will be 100 amperes, $\frac{I_w}{I_k} = 0.50$, that is to say, the short-circuit current will be $I_k = 160$ amperes. The full-load excitation (in accordance with curves) will be 169 amperes, the saturation coefficient of the open-circuit curve S = 0.60. The rise in voltage will then be 17 per cent for $\cos\phi = 0.80$, while the corresponding figure for unity power-factor will be 6.2 per cent. For the sake of argument we will assume that the price for this machine will be £1 per kilowatt.

Now we will take the case of a specification which calls for rather a low voltage-regulation figure, as can be obtained without great difficulty on slow-speed alternators. We will take, for instance, 14 per cent for $\cos\phi = 0.80$, and 4.5 per cent for unity power-factor. As it would not be advisable to work the machine at a higher flux density in order to flatten the open-circuit curve, the only means left for obtaining the lower regulation figures

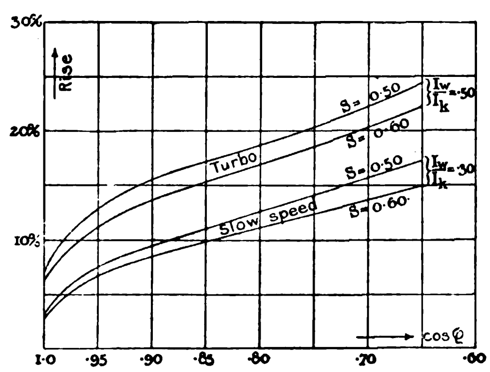

FIG. 4.—RELATIVE CHARACTERISTICS OF HIGH AND LOW-SPEED MACHINES.

would be to work it with a lower ratio of $\frac{I_w}{I_k}$, or, in other words, with a higher ratio of short-circuit current to normal current. Now, again, it is not possible simply to increase the excitation ampere-turns by increasing the gap, as the rotor field winding is already designed to the thermal limit. So, if no higher temperature rise is permissible, the desired result can only be obtained by a reduction in the rating of the machine. We will now find out how much that will be.

From curves we find that a ratio of $\frac{I_w}{I_k} = 0.40$ will give the figures specified. The rated current would therefore have to be reduced in the ratio $\frac{0.40}{0.50} = 0.80$. However, we can now make a correction, because for this lower output the exciting current will also be lower—namely, only 153 amperes, while our machine is designed to stand 169 amperes excitation. We can therefore increase the excitation ampere-turns in the ratio of $\frac{169}{153} = 1.104$ either by increasing the air-gap or by working the machine at a slightly higher density. This, however, enables us to put up our rated current to such a value that it still fulfills the relation $\frac{I_w}{I_k} = 0.40$. As I_k is proportional to the no-load excitation, it follows that we can increase I_w proportionally to the permissible increase in excitation. We therefore find that the rating of our machine is to be $0.80 \times 1.104 = 0.884$ of the standard rating. The price per kilowatt would therefore now be $\frac{1}{0.880}$ = £1.132 per kilowatt.

A small reduction is perhaps possible, because the stator copper can be reduced by 11.6 per cent, corresponding to the reduction of normal current output. So we can say the reduction in voltage rise from 6.2 per cent to 4.5 per cent at unity power-factor, and from 17 per cent to 14 per cent at $\cos\phi = 0.80$ is to be paid for by an increase in cost of 13 per cent.

It must, however, be kept in mind that this figure only holds good in case the modified output of the machine happens to coincide with the output called for in the specification. In reality specifications are accustomed to call for outputs in round figures, and the manufacturers also design their standard machines to give an output in round figures. If, therefore, a voltage regulation is specified which falls outside the figures of a properly designed standard line, it will, in most cases, be necessary to put in the next larger size of machine, so that the price per kilowatt will still be increased.

POWER-FACTOR.

I will now deal with the rated power-factor and its influence on the rating and the price of the machine.

It seems to suggest itself to the buyer of an alternator that he will be on the safe side if he orders the machine for a lower power-factor than is actually prevailing in his power station. As a matter of fact, this is very often done in practice. We will now see what he is to gain by this method.

We take again, for the sake of comparison, the same standard machine as before, with a price of £1 per kilowatt. Now, we will assume that, for the sake of getting a "bigger machine," the power-factor be specified as 0.70, while the actual power-factor in the station be 0.80. For

1,000 kilowatts the current at $\cos\phi = 0.70$ would then be $I_n = \frac{80}{0.70} = 114.2$, and $\frac{I_n}{I_k} = \frac{114.2}{160} = 0.715$. The curve for $\cos\phi = 0.70$ shows that for this load an exciting current of 192 amperes would be required, while the permissible current for the standard machine is only 169 amperes. This would mean about 35 per cent more heat in the field, with a correspondingly higher rise, which, of course, is not permissible. We have, therefore, to reduce the current output of our machine to such a value that at a power-factor of 0.70 the full-load excitation is equal to the normal figure of 169 amperes. From the same curve we find this armature current to be $= 0.556\ I_k = 90.5$ amperes; this gives a watt current $I_w = 0.70 \times 90.5 = 63.4$ amperes against 80 amperes of the standard machine. In other words, the output of the standard machine is reduced to $\frac{63.4}{80} \times 100 = 79.2$ per cent, or 792 kilowatts, and therefore the unit price increased by 26.5 per cent. This, of course, refers to the output stated on the nameplate to specification. The fact, however, that the actual power-factor is 0.80 instead of 0.70, as specified, will enable the station engineer to take more output out of the machine than is stated on the nameplate. The latter gives him as normal stator current the figure 90.5 amperes. With this current at his actual power-factor of 0.80 he can get a watt current of $0.80 \times 90.5 = 72.5$ amperes against 63.4 amperes, at $\cos\phi = 0.70$. He will therefore be very happy that, by specifying a lower power-factor, he gets an increase of output of 14.2 per cent "for nothing," or that the price per kilowatt which he actually gets out of his machine is only 87.5 per cent of the "nominal" price per kilowatt "rated" output. However, if he were aware of the fact, explained before, that the price per "rated" kilowatt of this machine is 26.5 per cent higher than it would be if designed for the correct power-factor, he would come to the conclusion that his unit price is actually $1.265 \times 0.875 = £1.107$ per kilowatt, while it would have been £1.00 per kilowatt if the machine had been built to suit the actual requirements.

In other words, he does not get 14.2 per cent more output "for nothing," but he pays 10.7 per cent more money "for nothing." Or probably still more, because it will, in most cases, happen that on account of the low power-factor the next larger standard will be put forward.

In order to make these facts still more evident, we can make the following comparison: The standard machine would be designed for 100-ampere stator current and 169-ampere rotor current, both windings being so dimensioned as to give the permissible temperature rise. The machine, which is actually put forward "to meet the requirements of the specification," will be designed for 90.5-ampere stator current, and 169-ampere rotor current—that is to say, with less stator copper, these two currents referring to $\cos\phi = 0.70$. The machine, however, will be run under actual load conditions with its rated stator current of 90.5 amperes (but with increased kilowatt output corresponding to $\cos\phi = 0.80$). From the curve for $\cos\phi = 0.80$ it is found that the necessary exciting current for $\frac{I_n}{I_k} = \frac{90.5}{160} = 0.566$ will be 161 amperes, or eight amperes less than the permissible current of 169 amperes. From this it is evident that although the engineer takes 14.2 per cent more output out of the machine above its rated capacity, he does not get the full benefit out of the capacity of the rotor, and if he would try to do this he would exceed the thermal limit of the stator.

It is therefore only to the interest of the customer to specify the actual conditions of power-factor under which the machine is to work, and not to include a margin where it is only detrimental to himself to do so.

SUMMARY.

The following are the conclusions to be drawn from my investigations:

1. If large turbo units are to be installed the problem of ventilation is not to be neglected, as one has to deal with large quantities of energy produced in a relatively small space. The best scheme seems to be to provide ducts for getting fresh air from outside the building to cool the machine and for taking the hot air away without allowing it to enter the engine room.

2. When specifying the voltage rise of a turbo-alternator due allowance should be made for the fact that the figures obtainable are not so low as those which can easily be obtained with multipolar machines. As fair figures for turbo-alternators can be regarded—

5 to 7 per cent for unity power-factor;
13 to 15.5 per cent for $\cos\phi = 0.90$; and
15 to 18 per cent for $\cos\phi = 0.80$.

3. When specifying the power-factor at which a turbo-alternator has to work, it is of no use to put in a lower figure than is actually prevailing in the station, as nothing can be gained by this, and it would, if anything, decrease the possible output of the machine.

Receivers Appointed for the Rockingham Power Company.

Receivers were appointed on November 23, by Judge J. C. Pritchard, of the United States Court, at Rockingham, N. C., for the Rockingham Power Company. William H. Browne and W. A. Leland were named.

The application for the appointment of receivers was made by the S. Morgan Smith Company, of York, Pa., manufacturer of hydraulic apparatus and waterwheels, who had the contract to supply and install the waterwheels and adjunct parts for the plant. The petition was made by this company, both as contract creditor and as a large owner of the bonds and stock of the Rockingham Power Company. The bill of complaint alleges that dissension among the members of the board of directors, and the action of the firm of Hugh McRae & Company, of Wilmington, N. C., who had undertaken to seize certain property essential to the development of the plant, and of which the company is said to be the equitable owner, and out of which seizure conflicts have taken place, impaired the credit and militated against the efforts of the majority of the holders of the bonds and of the board of directors and management in the procurement of additional funds required for the completion of the plant.

Mr. Leland has been in charge of the construction work, and Mr. Browne has been general manager of the company.

At the beginning of the year the bondholders of the Rockingham Power Company appointed from among their members a reorganization committee, which formulated a plan of procuring the additional money needed for the completion of the plant.

Under the order of the court, the receivers are continuing the work of construction, carrying it on in the same manner as it had been proceeding prior to their appointment.

New Independent Telephone Company.

The Valley Home Telephone Company, a corporation which is to take over practically all the so-called independent telephone interests in northeastern Michigan, including the exchanges at Saginaw, Bay City and Flint, has been organized. The authorized capital of the new company is $2,500,000, divided into 25,000 shares.

Chicago Traction Consolidation Under Consideration.

From time to time during the past year tentative negotiations have been made looking to the consolidation of the four elevated railway companies in Chicago. These have never met with success, owing to inability to agree on the financial readjustments that would be required. During the past week or so such negotiations have been resumed on what was said to be a larger and more promising scale. It was proposed now to merge not only the elevated railways but the surface lines as well into a huge unified corporation controlling practically all the traction facilities of Chicago and its suburbs. There would seem to be greater difficulty in harmonizing so many interests in view of the previous partial attempts. However, the task has been asserted to be less formidable because of a number of features that are aiding the consolidation idea. These are a general sentiment in its favor on the part of the municipal authorities and the public as a whole.

The present negotiations, unlike many of the previous ones, are being pushed by local financiers and capitalists that are directly concerned in the several properties. A number of conferences have been held under the direction of John J. Mitchell, president of the Illinois Trust and Savings Bank, and Samuel Insull, president of the Commonwealth Edison Company. At one of the meetings these two gentlemen with Chauncey Keep, John A. Spoor, Henry A. Blair, W. U. Eisendrath and Wallace Heckman were appointed a committee to consider the subject in all its aspects. These gentlemen represent the New York financiers as well as the Chicago interests, and practically assure the careful consideration of any consolidation project on the part of all financially concerned. If the merger is carried out to take in all the traction interests of the city, i. e., the four elevated and two surface companies, the total capital in stocks and bonds that will be involved will be close to $200,000,000.

Later accounts, however, seem to indicate that the present move will be confined to the Chicago City Railway Company and the Chicago Railways Company, which control practically all the surface lines in the city and have a combined capitalization of about $100,000,000. These two companies are now operating under the similar traction ordinances passed by the City Council in February, 1907, and approved by popular vote in April of that year. Under the supervision of the Board of Supervising Engineers, Chicago Traction, they are rehabilitating their systems on a plan contemplating ultimate unified control.

The Commonwealth Edison Company has been mentioned in the present negotiations as being one of the parties to the enlarged consolidation scheme. This statement is denied by the officials of the company. Its interest in the plan is indirect and arises from the fact that it is under contract to supply all the electric power for the Chicago City Railway and the Chicago & Oak Park Elevated Railroad as well as a large percentage of the power required by the Chicago Railways Company and the Metropolitan and Northwestern Elevated railways.

Harlem River Line to Be Electrified.

Application has been made by the New York, New Haven & Hartford Railroad Company and the Harlem River & Port Chester Railroad Company to the New York State Public Service Commission for permission to change the motive power of the latter road from steam to a high-potential alternating electric system similar to the system in use on the New Haven's main line between New York city and Stamford. It is believed that the intention is to make the smaller line the main line eventually and to establish connections through it with the New York Connecting Railroad in Queens and with the proposed Lexington Avenue subway which President Mellen of the New Haven has said his company may offer to build.

The petition sets forth that the New Haven is the lessee of the Harlem River & Port Chester Railroad, and that as it is now operating its main line by electricity, it desires to extend the same system to the operation of the leased lines.

The company states that it intends to finance the project from the proceeds of an issue of $15,000,000 of bonds known as the New York, New Haven & Hartford-Harlem River & Port Chester first mortgage four-per-cent fifty-year gold bonds. This issue was secured by a first mortgage dated May 16, 1904, made to the United States Trust Company as trustee. The issue was consented to by the then Board of Railroad Commissioners on September 6, 1904.

Should the applicaton be granted and the improvement installed the New Haven will have an outlet for its passenger traffic over the Connecting Railroad, and thence through the Pennsylvania's East River tunnels to Manhattan. If eventually the company should build and operate the Lexington Avenue tunnel, as Mr. Mellen once stated he hoped would be the case, the local passenger traffic will doubtless be diverted from the main line at the Mott Haven yards and sent into Manhattan through the new subway.

Successful Starting Up of the 6,000-Horsepower Motor at Gary, Ind.

The 6,000-horsepower, three-phase, twenty-five-cycle induction motor installed in the rolling mill of the Indiana Steel Company at Gary, Ind., by the General Electric Company, was started for the first time on Sunday, November 29. This is the largest individual motor unit in the world, and was assembled and erected on its own foundation ready for actual service before any tests of the machine were possible.

Two 2,000-kilowatt Curtis turbines were put in operation to supply the current for the motor, but at first the question of applying the 6,600 volts direct gave the engineers some concern. It was confidently determined, however, by the erecting engineers that the General Electric system of step-by-step control, using a master controller, would take care of the high voltage. This master controller gradually inserts resistance in a number of steps, starting at 1,350 volts, to full voltage.

To the satisfaction of everyone present, the motor started in the right direction—counter clockwise—and attained full speed in forty-five seconds. The starting or magnetizing current at the first jump was indeterminable, and for the following thirty seconds stood at 540 amperes, gradually dropping down to eighty-five amperes. Owing to outside conditions—the turbines feeding South Chicago at the same time—the voltage was about 5,600 during the first part of the test.

The operators in charge of the turbines reported a very satisfactory operation of these prime movers, and the meter readings were satisfactory at the meter board.

One can imagine the size of this equipment when it is known that it requires 300 gallons of lubricating oil in each of the bearings.

Telephone Injunction.

United States Judge Tayler, at Cleveland, Ohio, has issued an injunction restraining the American Telephone and Telegraph Company and the Central Union Telephone Company, both of them allied with the Bell system, from alleged interference with the business of the independent companies operating in Ohio, Indiana, Illinois and adjoining states.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

THE INFLUENCE OF ROENTGEN RAYS ON THE STARTING OF THE BRUSH DISCHARGE.

A paper on this subject was read by E. Marx at the annual meeting of the Association of German Physicists and Physicians. In order to measure the velocity of the Roentgen-rays, the author made use of their property of facilitating the starting of the brush discharge when they strike the negative pole of a spark gap. As there existed no record of an experimental investigation of this pole-releasing effect of the Roentgen-rays, the author examined their influence on a spark gap in a direct-current circuit, consisting of a platinum electrode and an aluminum window. This arrangement was chosen for the reason that it had previously served for determining the velocity of the rays. The aluminum window was grounded, and the platinum electrode, upon which the Roentgen-rays impinged, was alternately used as anode and cathode. It was demonstrated that in the first case the discharge was not only facilitated by forty per cent, but that—and this was so far unknown—in the second case the discharge took place with considerably greater difficulty than when no Roentgen-rays fell on the spark gap.—*Translated and abstracted from Physikalische Zeitschrift (Leipsic), November 1.*

WIRELESS TELEPHONY.

In the course of a description of wireless telephone systems, with which notable results have lately been achieved, it is stated that the Danish engineer, Valdemar Poulsen, has established perfect wireless telephone communication at a distance of 270 kilometres between two stations in Denmark. The primary energy was 900 watts, the radiated energy 300 watts; the masts were about sixty metres high and the wave-length was 1,100 to 1,200 metres. Communication was also established between Linkby and a station near Berlin, a distance of 500 kilometres. The German Gesellschaft für Drahtlose Telegraphie has developed the Telefunken system and has established satisfactory communication between Rheinsberg and Berlin, a distance of seventy-five kilometres. The masts used were twenty-six metres high, the primary energy 440 volts and five amperes. De Forest has reached distances of twenty-five miles by means of the arrangement devised by him.—*Translated and abstracted from Elektrotechnischer Anzeiger (Berlin), October 29.*

EFFECT OF ELECTRIC STREET RAILWAYS ON MAGNETIC OBSERVATORIES.

The opening of an extension of the Potsdam electric street railway had to be delayed on account of objections raised by the Magnetic Observatory there until the cause of disturbances noted had been removed. The authorities had originally made the condition that the magnetic disturbances caused by the operation of the railway should not exceed 0.00001 centimetre-gramme-second at the Observatory. The old railway fulfilled this requirement by adopting a method devised by its manager of feeding and insulating the rails, so completely, that the allowed limit of disturbance was approached only within fifty per cent. Similar conditions were made for the new extension from Potsdam to Nowawes, which approaches the observatory within 1.1 kilometre. The same method of feeding and insulating the rails was adopted, and during the final test the installation did not cause greater disturbances than were expected from calculations, amounting to 0.000003 centimetre-gramme-second. But during a preliminary trial an erroneous connection was made and two separate rail nets were charged with current under a difference of potential of sixteen volts, which gave rise to earth currents and distant magnetic effects of about tenfold strength. Against this disturbance resulting from the preliminary test the authorities raised objections.—*Translated and abstracted from Elektrotechnische Zeitschrift (Berlin), November 5.*

EXPLOSION GAS TURBINE OR COMBUSTION GAS TURBINE.

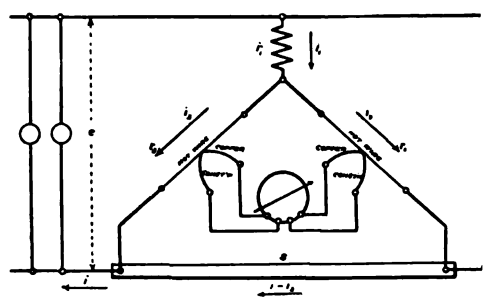
The present installment is a continuation of an article previously noted in these columns, the explosion turbine being dealt with. Such a machine might be constructed by sending explosive mixtures of gas and air into a series of explosion chambers by means of a compressor in such a way that one chamber will explode after the other in regular succession, and leading the exploded gases into a turbine. An arrangement of this kind with ten explosion chambers has actually been constructed, but the combination of so many different turbine elements intended to work in common is a source of great loss. Besides this, the apparently simple problem of supplying the explosion chambers with gas by means of special compressors, which are in turn dependent on the turbine, is difficult to carry out in practice and causes unreliability of operation. Drawings are shown of an arrangement which appears to the author more practicable. The compressor, explosion chamber and partly, also, the turbine, form one and the same part of the gas turbine and successively perform the various functions. Calculations of the theoretical efficiency of this arrangement are given in detail. The conclusion arrived at is that the thermo-dynamic prospects of the explosion gas turbine are not brilliant; however, an absolute thermal efficiency of fifteen to twenty per cent can be attained, and competition with the steam turbine will therefore be possible. A factor in favor of the gas turbine is its simplicity, due to the absence of the steam boiler. The explosion turbine seems to be the only possible solution of a gas turbine, and its success will depend in a large measure on its perfect construction, which can be developed only by practical experience.—*Translated and abstracted from Die Turbine (Berlin), October 20 and November 5.*

THE STERILIZATION OF WATER BY OZONE.

The Siemens & Halske Company has been manufacturing for some time three standard sizes of sterilizers—a laboratory apparatus, an apparatus for small communities or factories, and a portable apparatus for army purposes. In each type the essential elements comprising the sterilizer are an ozonizer, an electrically-driven compressor with the necessary accessories, a high-tension transformer, a sterilizing column, and a measuring arrangement. The construction of the ozonizer differs in the various models, but in principle it consists of discharge tubes, each element being composed of two concentric tubes, the outer one of glass being immersed in cooling water; the inner one is of aluminum or glass, and in the latter case it is filled with water for conducting the current. The compressor draws the air through drying tubes, blows it through the ozonizer, where it is electrified, and then into the sterilizing tower. This is a simple scrubber, a column of glass or sheet metal filled with glass balls or pebbles, through which the water percolates from the top and is brought in contact with the purifying gas during its passage. The measuring arrangement consists of a glass vial with a mercury seal filled with a solution of iodide of potassium, a gas meter for measuring the ozonized air, and an aspirating vial, which, when once graduated, may take the place of the gas meter. This vial is not necessary when the pressure is sufficient to drive the gas through the solution. The laboratory model can be attached to incandescent-lamp sockets. It is capable of treating 500 to 1,000 litres of dry atmospheric air an hour (ozone contents five to six grammes) and consumes one-fourth to one-half horsepower; if oxygen is used, the ozone is doubled or tripled. The portable outfit intended for army use has been adopted by some governments, especially Russia. It is carried on two wagons, weighing about 900 kilogrammes each, and is guaranteed to sterilize from two to three thousand litres of water an hour, utilizing, under ordinary conditions, not more than one-half or one-third of the ozone produced. The output of the ozonizers is illustrated by curves, which show that the production of ozone per horsepower-hour increases with the velocity of the flow of air through the ozonizer. However, the concentration of the ozone—that is, the number of grammes per cubic metre of air treated—diminishes under the same conditions. This is explained by the fact that, when the air circulation is slow, the ozonizing effect is immediately followed by decomposition. In practice, it is impossible to go below certain limits with the concentration.—*Translated and abstracted from L'Electricien (Paris), November 7.*

THERMO-WATTMETERS.

For the purpose of measuring high-frequency currents, R. Van Cauwenberghe has devised an arrangement consisting of two Voege thermo-elements and a differential galvanometer, thus constituting what he terms a thermo-wattmeter. The principal quality of the arrangement is that it possesses no appreciable self-induction or capacity and offers no skin-effect, even with frequencies as high as 10,000 periods per second. The thermo-element of Dr. Voege consists of a straight hot wire soldered in the middle to the place where the elements, copper and constantan, unite, the entire element being enclosed in a rarefied atmosphere. This thermo-element is much more sensitive than that with a spiral, but requires the use of a differential galvanometer in order to prevent the current intended for the galvanometer from being partially shunted



CONNECTIONS FOR THERMO-WATT-METERS.

by the hot wires connected in series. Galvanometers with permanent magnets and two-wire movable coils are recommended. The author expresses the fear, however, that long use may cause a modification of the elements and be detrimental to the accuracy of the measurements. The circuit arrangement is shown in the accompanying diagram.—*Translated and abstracted from La Lumiere Electrique (Paris), October 31.*

AN ELECTRICALLY-DRIVEN ROLLING MILL.

The electrical equipment of Dorman, Long & Company's wire mills, at Middlesbrough, in the northeastern district of England, has recently been completed by the Electrical Company, Limited. The operation of the reversing rolling mill is on the Ilgner system, in connection with Ward Leonard control. The Ilgner set consists of a flywheel, motor-generator, the generator of the direct-current type, coupled in series with the mill motor. The generator field is controlled by an exciter, and the variation or reversal of the small exciting current provides for the entire control of the rolling-mill motor. The stored-up energy in the flywheel is made to neutralize the otherwise heavy current demands at periods of peak load on the mill, this being achieved by compulsorily decreasing the speed of the Ilgner set during such periods by means of a liquid resistance automatically governed by a regulating motor, which introduces resistance into the rotor circuit of the driving motor as required. The torque exercised by the regulating motor varies with the main current. An increase of the latter to maximum value enables the regulating motor to lift the electrodes, and thus introduce the necessary resistance; while, on the other hand, a decrease in the main current to a predetermined value, such as occurs when the mill runs empty at the end of a pass, decreases the motor torque, allowing the electrodes to fall, and ultimately short-circuit the rotor of the driving motor of the Ilgner set, which consequently speeds up, enabling the flywheel to store energy for the next peak load on the mill. The plant at the Dorman works operates a rolling mill containing two housings with sixteen-inch-diameter rolls, intended for rolling angles and small girders. The mill is coupled to a compound-wound, 600-volt motor of 1,200 horsepower capacity, with a maximum output of 3,600 horsepower, and a varying speed of from zero to 110 and 160 revolutions per minute. The maximum torque of the motor is 232,000 foot-pounds. The Ilgner set consists of a 950-horsepower motor, operating on three-phase current at 2,750 volts pressure, forty cycles, coupled direct to a 1,250-3,600-horsepower dynamo, giving 600 volts, and attached by a coupling to two twenty-ton flywheels mounted on a separate shaft. If the maximum demand of the rolling-mill motor on certain work does not exceed 950 horsepower, it is possible to disconnect the flywheels. The Ilgner generator is provided with compensating coils on the Deri system for the purpose of reducing the armatutre reaction, securing sparkless commutation at all loads, with a fixed brush position. To start the Ilgner set, a special barring gear is provided, consisting of a fifteen-horsepower motor, with the necessary gear, this being cut off automatically when the set reaches a speed of three revolutions per minute. The flywheels, which are each fourteen feet in diameter, are equipped with powerful water-cooled brakes for quick stopping. The exciting set consists of one three-phase motor of eighty horsepower capacity, running at 2,750 volts, forty cycles, coupled direct to two continuous-current dynamos, one of which serves to excite the fields of the Ilgner generator and the mill motor, and the other excites a special compound winding on the mill motor. This is with the object of strengthening the field, and thus decreasing the speed at sudden heavy overloads.—*Abstracted from the Electrical Review (London), November 13.*

INDUSTRIAL SECTION

ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

The Ridgway Side-Crank Engine.

Well-informed engineers recognize that for some purposes the side-crank type of engine construction is most satisfactory, although to produce a machine of this type certain valuable features of the center-crank engine must be sacrificed. Constructed with a view toward the high quality which characterizes its well-known center-crank line, the Ridgway Dynamo and Engine Company, Ridgway, Pa., has brought out the Ridgway side-crank engine. Like the older line, this engine has been designed for simplicity, strength and quality.

In the construction of these engines the best materials are used by skilled workmen, and all parts are made to standard gauge and are interchangeable wherever possible. After passing numerous inspections the completed engine is erected on the testing floor, connected to a dynamo loaded with a water rheostat, and subjected to a test lasting from ten to twenty-four hours, under full and overload conditions.

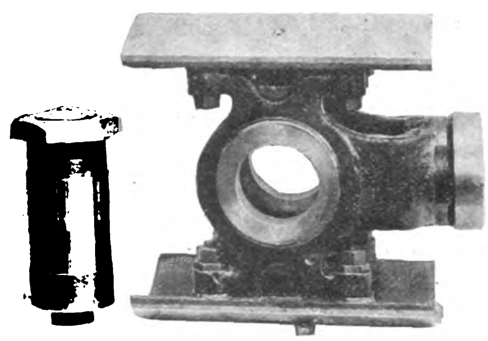
The engine bed is of heavy design throughout, with the metal so distributed as to bring the heaviest sections in line with the greatest strains. Careful consideration for small details, as well as for pleasing outlines, has been observed. The main part of the bed is of a box section having bored guides of large diameter. The guides and end for the cylinder are bored and turned at one setting, insuring the perfect alignment of bed and cylinder.

At the cylinder end of the bed is a removable partition which prevents oil from being thrown against the end of the cylinder. Between the cylinder and the partition is a well in which the drip from the stuffing-box is caught. The water is removed by an efficient separator, and the oil flows back to the crank pit. The crank disc is covered with an oil-tight guard of light sheet steel, hinged at the top so that it may be turned back over the bed, giving access to the connecting rod and crank-pin.

The main bearing on all sizes is of the quarter-box type. The shells are lined with babbitt metal peened in place and bored out in accurate jigs, and are, therefore, interchangeable in engines of the same size. Horizontal adjustment is secured by a wedge, and vertical adjustment by drawing down the cap.

The connecting rod is forged from open-hearth steel and is designed with a minimum factor of safety of fifteen. The straps at both ends are slotted out of the solid forging. The wrist-pin box is of phosphor-bronze, while the crank-pin box is lined with babbitt peened and bored. Both ends are adjusted by the wedge and bolt method.

The cross-head body is of cast-steel of a substantial design. The lower shoe is adjustable, and, besides bolts, means have been provided for adjusting both top and bottom shoes by the use of shims, if desired. The wrist-pin is provided with keys so that it may be turned ninety degrees as it wears.



CROSS-HEAD AND PIN, RIDGWAY SIDE-CRANK ENGINE.

The cylinder and valve on this engine are of the same design which the manufacturer has used for over fifteen years on the center-crank engines. The cylinder is cast of a hard, close-grained iron, and the barrel is covered by heavy polished cast-iron lagging. The valve is of the flat balanced type and moves between the seat and a heavy pressure plate. Cored ports in the pressure plate corresponding to those in the valve seat and connecting through side openings with the main ports, make this a double-ported valve. This construction gives an indicator card in which the steam line holds up well and cut-off is very sharp. In case of water being carried into the cylinder, the holding spring allows both valve and pressure plate to lift from the seat, permitting the water to pass into the exhaust. Relief valves are, therefore, not necessary.

The piston is a single hollow casting, strongly braced by ribs and made as light as is consistent with strength. The rod and piston are joined by a force-taper fit, supplemented by a jamb nut held by a set screw.

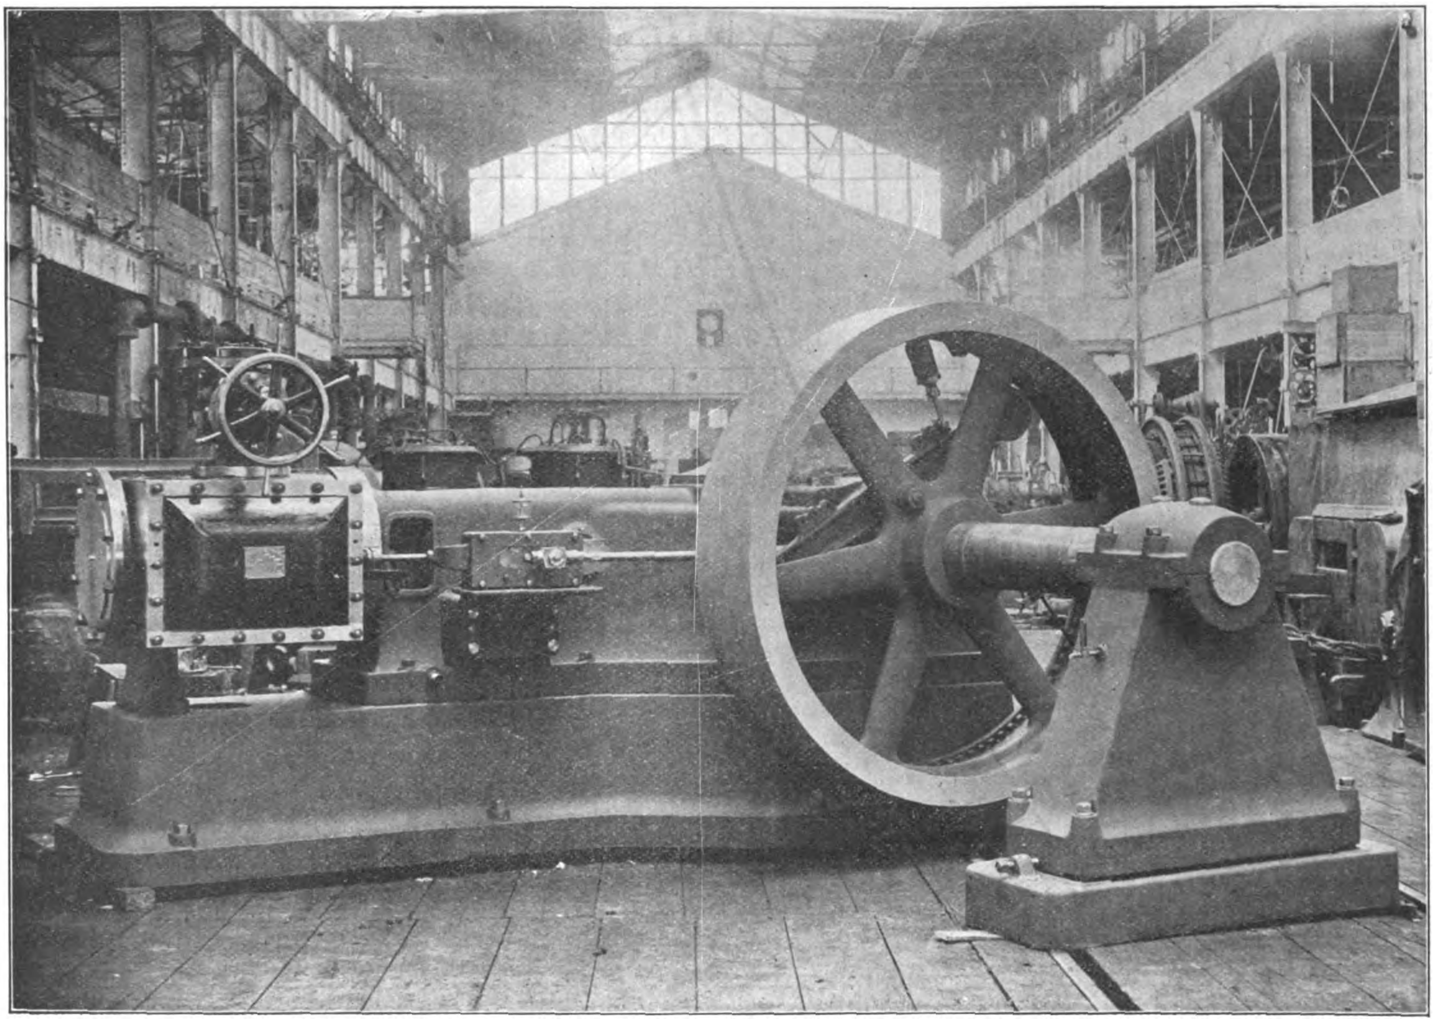
The main shaft is a single forging of the best open-hearth steel. It is extra large in the bearings and proportionately increased in the governor wheel hub. The crank disc is made of a mixture of cast-iron and steel designated as semi-steel, the result being a tough, close-grained, hard iron. The crank-pin is cast solid with the disc. The shape of the disc forms the counterbalance, a feature not secured on side-crank engines by using a circular disc. The fitted crank is forged to place on the shaft under hydraulic pressure and is secured by a heavy key.

The Ridgway governor, formerly known as the "Begtrup," was the pioneer inertia governor, and is described as follows: A long bar, called the inertia bar, having weights at each end, is pivoted at the center on a roller bearing. The inertia bar is lined with hardened steel bushings and the space between the main pin is filled with hardened steel rollers. This insures a minimum of friction and a bearing subject to very little wear. This is the only bearing requiring lubrication, although it will go without attention for several weeks. To the hub of this bearing is clamped the eccentric, which being split, is removable without disturbing the governor or the setting of the valve. A heavy coil spring is secured to the middle of one end of the bar. Opposite the spring is an oil dashpot, having its connecting rod bolted to the inertia bar. A by-pass with an adjustable opening allows the oil to circulate from one side of the piston to the other. The governor is reversible without the use of any extra parts.

The action of the governor is as follows: Rotating from right to left, the weight in the spring end of the bar being the greater, centrifugal force tends to swing it outward and backward toward the lower stop. This tendency to move backward is balanced by the spring, whose tension is such as to hold the inertia bar in equilibrium when the engine is at its desired speed. When starting up the eccentric travels in its greatest path, giving the valve its widest opening and latest cut-off. As the speed increases, centrifugal force acting on the weighted end of the inertia bar moves it backward to the lower stop, reducing the travel of the valve and cutting off steam earlier. This backward movement of the bar is continued until the travel of the valve reduces cut-off to the amount necessary to keep the engine rotating at its proper speed to give an even balance between centrifugal force acting on the inertia bar and the opposing tension of the spring. If a load is now applied to the engine, there is a check to the speed of the governor wheel, while the inertia bar, by reason of its momentum, rotates forward sufficiently to increase valve travel and give late enough cut-off to carry the load. Should the load be thrown off, this wheel tends to increase its speed, causing the inertia bar to swing backward and reduce valve travel and cut-off until equilibrium is re-established.

In harmony with the proportions of the bed and sub-base, the outboard bearing pedestal is built on liberal lines and made broad at the base to insure stiffness. The bearing is of the self-oiling, self-aligning type; the shells being lined with babbitt peened and bored. Vertical adjustment is accomplished by means of special devices used on the cross-head and applied to the four bolts at the base of the pedestal.

Two standard methods of lubricating the engine are provided. In the first, known as the "splash" system, the crank pit is filled with oil, which the disc throws in an almost steady stream over the cross-head and guides. Oil from the upper guide is wiped off by the top cross-head shoe and flows through passages and pipes to the cross-head pin. Pockets on the inside of the crank guard collect great quantities of oil which are led through ample passages to the main bearings and to the crank-pin. All bearings are, therefore, practically flooded at all times. This is the usual lubrication system furnished by the manufacturers. The other system uses a small but efficient filter placed in one side of a tank, which is mounted on the sub-base below the slide bracket. In the other side of the tank is a valveless pump driven by a cam on the valve-gear ram. This cam is designed to give a full stroke regardless of the travel of the ram. All oil from the bearings flows to the crank pit, from which it is piped to the filter, then passes to the pump chamber, where it is pumped to a large tank on top of the bed. From this tank the oil flows through nickeled piping to each bearing. Sight-feed valves are placed in each pipe near the tank so that the supply may be shut off or regulated. As the engine is fully enclosed, no oil can be thrown on to the floor or into the governor wheel. With either system the valve gear is supplied with grease cups.



ASSEMBLED VIEW OF RIDGWAY SIDE-CRANK ENGINE.

Ridgway side-crank engines are built in the simple, tandem and cross-compound types. In the compound types the low-pressure valve is of the balanced type, though slightly modified from the one previously described. On tandem engines both valves are driven by the governor, the low-pressure directly and the high-pressure by means of a tail-rod on the low-pressure valve. On cross-compound engines the high-pressure valve is driven by the governor and the low-pressure by a fixed eccentric on the main shaft. Simple and tandem compound engines are made from fifty to 800 horsepower, and cross-compound engines up to 1,500 horsepower.

The New Westinghouse Distributing Transformers.

The Westinghouse Electric and Manufacturing Company has just developed and placed on the market a new shell-type distributing transformer, known as the Type "S" which has ben worked out from theoretical consideration a well as from the practical results of many tests. In these transformers the most economical disposition of all the material used has been made, and the result is a line of transformers of small dimensions, liberal overload, high efficiency, great reliability and good regulation. Use has been made of a new alloy of steel, and the design so proportioned that remarkably low magnetizing or no-load currents are secured.

Distributing transformers must at all times be ready to furnish electrical power up to their maximum overload capacity.

VIEW OF TYPE S DISTRIBUTING TRANSFORMER.

Interruptions of the service not only cause pecuniary losses to the power company but, worse still, are a source of friction between the consumer and the central-station manager. In cases where the central station is under contract to furnish continuous service to its customers an interruption of the service is a very serious matter.

The reliability of a transformer depends largely upon the disposition, quality and amount of insulating materials used in its construction. The insulation must not only separate the different turns of the individual conductors, but must also act as a barrier between the high and low tension coils and between either circuit and the core. A failure to fulfill these duties will result in a partial or complete destruction of the transformer, interruption of the service and very often danger to life and property. The presence of a very small amount of moisture in the insulation of a transformer will greatly reduce its dielectric strength. This is one of the most frequent causes of breakdowns, and often very disastrous results occur when only the slightest trace of moisture is present. To avoid troubles of this nature the insulation should be treated in such a manner as to make it impervious to moisture.

In Westinghouse Type S transformers the insulation is non-hygroscopic, that is, it will not absorb moisture, and will not deteriorate under ordinary operating temperatures. It undergoes a rigid inspection before being used in the transformer, and the assembled core and coils are further subjected to high breakdown voltages for the purpose of discovering any defects in the insulation.

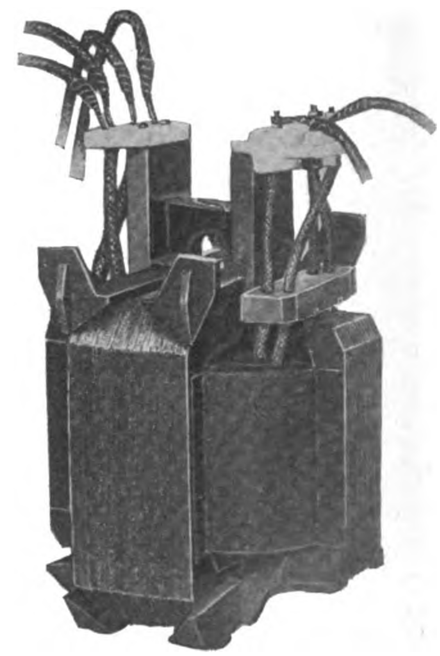
A vacuum impregnating process is used to remove the last traces of moisture and to form the winding and insulation into a solid, moisture-repelling unit.

Insulation deteriorates under high temperatures, due to the carbonizing action which takes place in fibrous materials. A low operating temperature is therefore necessary for the satisfactory service of the transformer. By low operating temperature is meant not only low average temperature, such as would be indicated by a thermometer in the oil, but also a low maximum temperature, that is, at no point within the coils should the temperature rise much beyond the average temperature of the transformer. A transformer with hot spots is as much to be avoided as one having a high operating temperature.

The construction of shell type transformers such as the Type S permits of large ventilating ducts between the coils. Through these ducts the oil circulates freely and is thus enabled to reach the innermost parts of the apparatus. This oil circulation effectually prevents hot spots and maintains a uniformly low temperature throughout the transformer.

Good ventilation also enables a transformer to carry large overloads without a dangerous rise in temperature. If a distributing transformer has a large overload capacity, it may be installed to supply power considerably in excess of its normal rating, providing this power is only required at intervals and for a limited time. This not only saves the increased cost of a large transformer, but also gives a higher average all-day efficiency, due to the lower fixed losses of the smaller unit.

The electrical performance of distributing transformers should be carefully considered. Those having high losses are unsuitable for central-station work, and this is especially true in cases where the cost of the production of the power is high. The efficiency of a transformer depends upon the iron or core loss and the copper loss. These losses represent energy delivered to the transformer for which no return is received. The iron loss is of particular importance, since it is a continuous loss as long as the transformer is connected to the mains. This fact is well recognized and nearly all transformers show a reasonably low core loss when new. In many transformers, if the core loss is measured after having been in service about twelve months, it will be found



TYPE S DISTRIBUTING TRANSFORMER, SHOWING COILS, TAPS AND CORE.

that this loss has greatly increased, due to what is known as the "aging" of the iron. The magnetic circuit of the type S transformer is built of a special grade of alloy sheet steel, which has been selected only after an extensive series of tests proving it to have practically non-aging qualities.

The regulation of a distributing transformer is a matter of prime importance both to the consumer and to the operating engineer. It depends principally upon the copper loss, and the per cent regulation is generally very little more than the per cent copper loss. If a transformer of zero regulation could be constructed and connected to the line the potential on the low-tension circuit would not change in passing from full load to no load. Distributing transformers should have as good regulation as possible. In type S transformers the arrangement and size of the conductors provide for an especially good regulation.

All these transformers under twenty kilowatts are mounted in smooth cast-iron cases which have a cooling surface sufficient to keep the transformers at normal temperature. The cases for transformers of larger sizes are made of cast-iron with corrugated sides, which greatly increase the area of the cooling surface. The leads are brought out through porcelain bushings which are babbitted into the case. The lead insulation is moisture-proof, and a sealing compound is poured around the leads where they issue from the case.

The core is built up of laminated sheet-steel punchings, each layer of laminæ being reversed with reference to the preceding layer. This gives a continuous magnetic circuit of low reluctance. The full benefit of laminating the iron is thus obtained with a resulting low core loss. All iron used in the cores of these transformers is subjected to rigid tests and inspection at the factory. Samples taken from the iron used are tested for loss and aging, and only those giving satisfactory results are accepted. The assembled transformer is also tested to make sure that no inferior iron has passed the previous tests. The assembled core consists of four magnetic circuits encircling the winding and protecting it from mechanical injury.

Type S transformers have the high-tension winding mounted concentrically between two low-tension coils. All coils are form wound and individually insulated, the insulation consisting of those materials which long experience has shown to be the best suited to this work. The low-tension coils of transformers above five kilowatts are wound from cotton-covered strap copper having a rectangular cross-section; transformers of a smaller capacity have wire-wound low-tension coils. The high-tension coil is form wound of cotton-covered wire. The conductors are of circular cross-section in the smaller sizes but are of strap copper in the larger transformers.

Between the high and low-tension coils are layers of paper and mica. After the core and coils are assembled they are baked in a vacuum tank which removes every trace of moisture. A hot liquid insulating compound under high pressure is then introduced into the tank. This compound is oilproof at all temperatures. It does not dissolve in the oil, fill the ventilating ducts and cause the transformer to run hot.

The high-tension winding has four leads brought to the studs in the terminal block. Adjustable brass connectors or links between the studs provide for series or multiple connections between two points of the high-tension winding. The position of the studs and the length of the links are so proportioned that wrong connections on the block are impossible. Barriers on the porcelain block separate the studs and prevent danger of arcing.

The fuses furnished with these transformers are mounted in a weatherproof porcelain fusebox. The stationary contacts are deeply recessed in the porcelain and are well separated from each other. The contacts are so constructed that the plug is held securely in place by giving it a partial turn after inserting it. When the plug is in position the fuse is in sight and its condition can be noted; this eliminates all danger of pulling the fuse while intact and the transformer under load.

Connectors are supplied with all Westinghouse Type S transformers for connecting the low-tension leads to the feeder wires. These connectors for the larger sizes of transformers are of the interleaved type and form a mechanically strong joint of high current-carrying capacity. By means of these a change can be made in the low-tension connections of a transformer, or one transformer removed and another of the same or a different capacity substituted usually without unsoldering or soldering a joint.

Type S transformers are made in sixteen sizes, from one-half to fifty kilowatts, and are designed for normally supplying 110, 220, and, in the larger sizes, 440-volt service from primary circuits of 1,100 and 2,200-volt and sixty-cycle frequency, although they are suitable, without change in the rating, for any frequency from fifty to 140 cycles.

Union Switch and Signal Contract.

The Union Switch and Signal Company has received the contract for the protection by signaling and interlocking of the McAdoo tunnels.

At the terminal stations of these tunnels, at Church and Cortlandt streets, New York city, the signaling work will be the most important. The Switch and Signal company will install at this station at once four electro-pneumatic interlocking equipments, and also the intermediate block signals and train stops. The latter will be actuated by compressed air; the signals will be electrically operated.

RECENT IMPROVEMENTS IN LIFTING MAGNETS.

BY ARTHUR C. EASTWOOD.

The first commercial lifting magnet was placed in service in this country about thirteen years ago. This magnet was designed by S. T. Wellman for handling plates and slabs, and proved fairly satisfactory for such service. The design was later refined and improved upon by E. B. Clark, then electrical engineer for the South Works of the Illinois Steel Company.

The manufacture of lifting magnets of both the Wellman and Clark types was taken up by the Electric Controller and Manufacturing Company (then the Electric Controller and Supply Company) more than ten years ago. A special magnet-testing machine was designed and installed, and much valuable data bearing on the design of lifting magnets were secured.

Many magnets of the Clark type have been manufactured and sold, and have given excellent results in the handling of smooth, homogeneous material, such as plates, blooms and slabs. These magnets, however, were useless for handling rough and detached material, such as pig iron, crop ends and scrap. A magnet which would readily lift a steel ingot weighing 10,000 pounds would not lift a single pig of iron weighing 100 pounds.

Many attempts were made to perfect a magnet for handling pig iron and scrap, since, obviously, the large amounts of such raw material handled by tedious hand methods at all steel and iron works and foundries offered a tremendous field for the saving of labor, providing a practical lifting magnet could be developed for the purpose.

Perhaps the first experiments in this direction which gave promise of commercial results were made at the West Seneca plant of the Lackawanna Steel Company, under the direction of E. D. Edmondson and L. R. Palmer, a lifting magnet being constructed which actually lifted pig iron, though in rather small quantity, taking into consideration the weight of the magnet and its current consumption.

The first commercially successful lifting magnet for handling pig iron, scrap and miscellaneous magnetic material was placed on the market by the Electric Controller and Manufacturing Company in March, 1905. This magnet was built in two sizes, commercially known as No. 1 and No. 2 Type S magnets. Over 150 of these magnets have since been placed in service, and, at a conservative estimate, have saved to the iron and steel trade of this country at least half a million dollars in the cost of handling material within the past year. This type of magnet has also been introduced in Germany and England.

In view of these facts, there can be no doubt that Type S magnets, as manufactured by the Electric Controller and Manufacturing Company, have become satisfactory and reliable tools—more dependable, in fact, than the cranes which carry them. This company, however, has not been content to rest upon the satisfactory results thus far obtained with its Type S magnets, but has been constantly at work on improvements, both in the direction of dependability and in increased efficiency in the handling of material.

Unquestionably, a successful lifting magnet must withstand in service more severe abuse and rough handling than any other type of electrical apparatus. In operation it is suspended from the hook of a crane (frequently not equipped with a lowering brake), and may be dropped at high speed upon the material to be lifted, which may be comparable almost to dropping the magnet from a second-story window. In service it will be swung against cars, charging boxes, piles of pig iron, etc., and must be capable of withstanding the blows and shocks which result. It must operate under all weather conditions, day or night, irrespective of rain or snow, and its insulation must withstand a voltage much higher than line voltage, due to the inductive kick which occurs when the circuit of the magnet is opened. Its winding must not be injured by the large amount of heat which is necessarily generated within it, and, preferably, also, should not be damaged by external heat when the magnet is called upon to handle hot material.

Fig. 1 is a typical cross-section of a Type SA magnet, and shows the arrangement of parts which by experience has been found to meet the severe and exacting requirements of service.

In Fig. 1, A is the body or framework of the magnet, which is an annular casting of special electrical steel heavily ribbed on both its upper and outer surfaces. The ribs serve to add largely to the surface available for dissipating heat, and are so disposed as to stiffen the magnet case mechanically and at the same time to add to the cross-section of the magnetic circuit.

B is the core of the magnet, which is surrounded by the winding C. This winding is composed of a series of coils, each wound with a conductor in the form of a copper ribbon or strap, the turns of which are insulated with asbestos ribbon. Neighboring coils are mechanically separated and electrically insulated by noncombustible insulating discs D. The coils are wound upon a heavy brass form E, which resembles a spool with one head re-

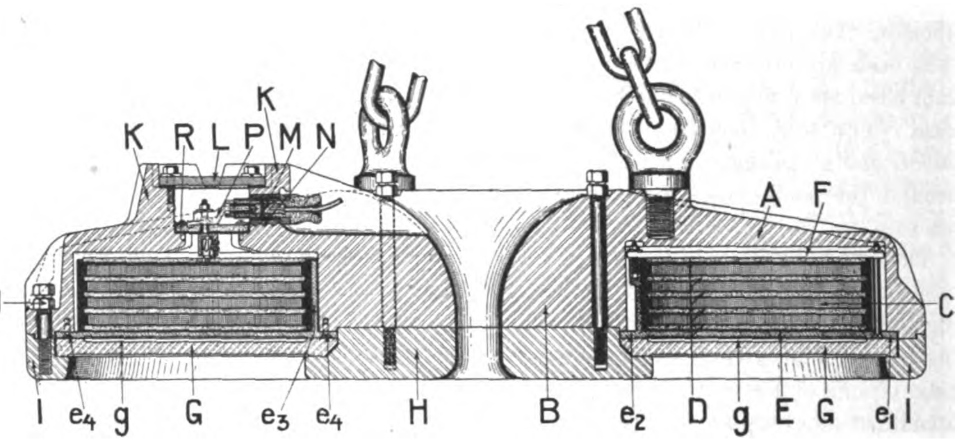


FIG. 1.—SECTIONAL VIEW OF ELECTRIC CONTROLLER AND MANUFACTURING COMPANY'S TYPE SA LIFTING MAGNET.

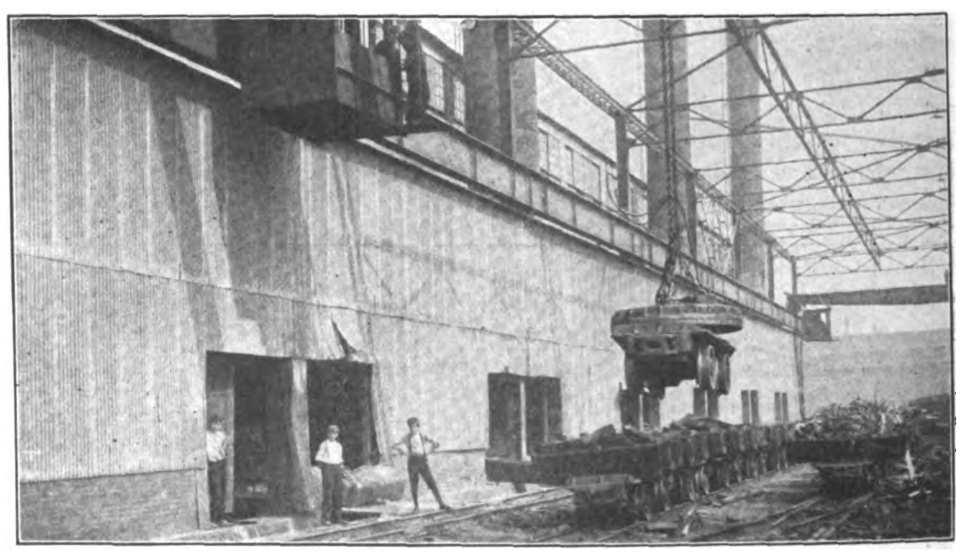
moved. This form serves to support the coils during the process of winding and insures coils of uniform and perfect shape, since there is no danger of springing or otherwise distorting the winding. After the last or uppermost coil is wound and the outer disc of insulation is in place, the entire winding is rigidly clamped to



NO. 6 TYPE SA MAGNET LIFTING BUGGY WEIGHING 70,000 POUNDS BY LINE CONTACT WITH SPACING RIBS—CARNEGIE STEEL COMPANY, HOMESTEAD, PA.

the form by means of radial straps F, which are bolted and locked in place, thus making the winding and the brass form which carries it a rigid unit. The completed winding is then dried in a steam-heated chamber under a vacuum, and when the initial drying process is completed the winding is impregnated with a plastic insulating compound, first, under the influence of a vacuum and then under air pressure and finally is again dried under a vacuum. This results in a winding not only fireproof—not a particle of combustible material being used in its make-up—but, what is of still greater importance, the winding is thoroughly waterproofed. The completed winding is then placed in the magnet case.

It will be noted that the form E is provided with an outer flange $e1$, and an inner flange $e2$, in addition to the central upwardly-extending flange $e3$, which centrally supports the winding. The inner and outer flanges are carefully finished and engage with finished surfaces on the inner and outer pole faces of the magnet case, thus completely sealing the lower face of the winding chamber, a water-tight joint being insured by clamping the flanges in place with screws $e4$, $e4$, spaced four inches apart, entirely around the flanges $e1$ and $e2$. Since the winding is clamped to the form E by the radial clamps F, and the form E is clamped in the magnet case by screws placed four inches apart entirely around its inner and outer edges, it will be readily seen that the winding is rigidly held against displacement.

With the winding thus assembled in the magnet case, the lower face of the coil form E is covered by a heavy annular plate of non-magnetic manganese steel G, which in turn is held in place by pole shoes H and I, bolted, respectively, to the inner and outer poles of the magnet case. Both of the pole shoes are provided with shoulders which protect the clamping bolts from shearing strains. The heads of the outer clamping bolts J are located between adjacent ribs on the outer surface of the magnet case, where they are protected from abrasion.

In the cross-sectional view it will be noted that the manganese steel plate G carries raised shoulders around its inner and outer peripheries, by means of which the plate is made to seat against the magnet poles, and an air space or cushion is left under the winding at g. This results in the shocks taken by the outer plate G being transmitted directly to the magnet frame instead of being taken by the winding, as would necessarily be the case if only a single-bottom plate were used.

The pole shoes are so disposed with respect to the outer plate G that none of the clamping surfaces can become battered over, and, therefore, the plate G may always be readily renewed.

It will be seen that the entire lower or wearing face of the magnet is renewable, and that these renewals can be readily effected in the field, there being no necessity of in any way exposing or disturbing the winding or breaking the water-tight joint between the coil form E and the frame of the magnet.

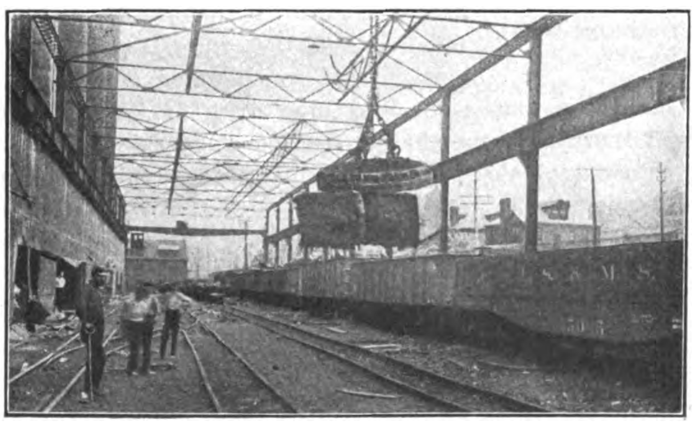
The arrangement of terminals also deserves attention, since, no matter how good the design in other respects, if the terminal construction be weak, trouble is certain to result from this cause.

In Type SA magnets the terminal cavity is surrounded by raised walls K, K, cast integral with the magnet case and of such thickness as to be as strong as the magnet case itself. The terminal cavity is closed at the top with a heavy steel cover L, which seats against a gasket to form a water-tight joint, and is firmly bolted in place, the heads of the bolts being protected from abrasion by the walls of the terminal cavity. All of the terminal parts are thus enclosed in a water-proof box of steel. The terminals themselves, as in the earlier Type S magnets, are of the plug type, which permits of quick attachment and detachment of the service wires. Numerous improvements, however, have been made in the details of construction. The female members M of the terminal are enclosed in an insulating tube, so that a ground or short-circuit cannot result, even if the service wires are left hanging from the crane with current on. The insulating tubes are each encased in a steel tube to prevent abrasion of the insulation, and these steel tubes fit closely in babbitted openings N in the side of the terminal chamber. The male members P of the plug connectors are mounted upon a heavy plate R of fire-proof insulating material, which closes the entrance to the winding chamber and is seated upon a gasket to effect a water-tight joint. The plugs proper are separable from the terminals by removing the nuts which hold them in place. The plugs and also the plate R may therefore be removed without throwing any strain on the connections to the winding, the connections consisting of loops of very flexible copper ribbon, these loops being stowed away in the box-like ends of the terminal studs. This construction permits of great flexibility and at the same time makes it impossible for the flexible leads which connect to the two ends of the magnet winding to come into accidental contact. These features of construction indicate how carefully the design of Type SA magnets has been thought out and worked out from a mechanical and electrical standpoint.

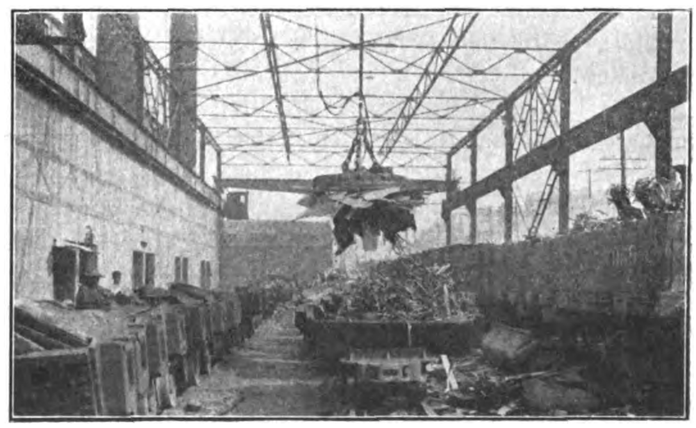
In additon to these structural features the Electric Controller and Manufacturing Company has incorporated in the design of Type SA magnets the results of long experience and careful study.

By maximum efficiency is meant the ability to handle the largest amount of material in a given time with minimum total consumption of current. In this respect the results obtained with Type SA magnets far surpass any results which have been obtained in the past. As an instance, the No. 4 Type SA magnet, forty inches in diameter, lifts substantially as much as older forms of magnets of fifty inches in diameter with substantially the same current consumption, but weighs 2,000 pounds less. Comparing the performance of the two magnets on a five-ton crane having a twenty-five-horsepower hoist motor, with equal lifts, the No. 4 SA magnet has the advantage of 2,000 pounds in total load to be lifted, or twenty per cent of the total hoisting capacity of the crane. This will mean a saving in current consumption of twenty amperes on the part of the hoist motor, and by virtue of this lower current consumption and lighter load, the hoisting speed will be higher and the amount of material handled in a given time will be materially increased.

Proportionate increases in efficiency are shown by the No. 5 and No. 6 Type SA magnets, the No. 6 magnet being without question the most powerful commercial lifting magnet which has ever been constructed.



NO. 6 TYPE SA MAGNET HANDLING TWO INGOT BUTTS, NOT WEIGHED—CARNEGIE STEEL COMPANY, HOMESTEAD, PA.



NO. 6 TYPE SA MAGNET HANDLING SHEET SCRAP, WEIGHT 1,200 POUNDS—CARNEGIE STEEL COMPANY, HOMESTEAD, PA.

Advertising with Flame Arc Lamps.

The first flame arc lamps used in this country were of foreign manufacture. It was, however, only a comparatively short time after their introduction that American manufacturers awoke to the realization that the lamp was destined to play an important part in decorative lighting. The result was that at the present time there are several American-made lamps on the market, all of which are widely advertised.

Although in foreign countries the flame arc lamps has been widely adopted for street illumination, its use in this country is confined principally to the illumination of store fronts and amusement places such as theatres, parks, etc. While its use in connection with mercantile establishments is principally to attract attention, it can at the same time be used to advantage for the illumination of the store windows, thus serving a double purpose. For this service the lamps are suspended from suitable supports just above the top of the window.

To the brilliant light emitted by the flame arc lamp when in operation is due its advertising or attention-attracting quality. The entire globe seems filled with a luminous gas, and, although the light has the property of penetrating the thickest fogs or smoke, it is soft and not blinding to the eye like the enclosed arc. Carbons giving a yellow or orange colored light are generally used, but carbons may be obtained that will give a light of a red or white color.

Fig. 1 shows the front of a department store in Schenectady, N. Y., lighted with four flame arc lamps of a type manufactured by the General Electric Company, Schenectady, N. Y. This illustration was reproduced from a photograph taken solely by the light of the lamps, and although it fails to show the true beauty of the illumination, gives an idea of how the store appears at night. This is only one of many similar installations in this city, and it is interesting to note that the merchants have clubbed together and made arrangements to have the entire business section lighted with G-I flame arc lamps. The lamps will be spaced at equal intervals along both sides of the street and at the same height from the sidewalk.

In Fig. 2 is shown an exterior view of the lamp. In this type of lamp several good points of construction may be noted. All clock mechanism is eliminated, thus producing a lamp of simplicity and one free from the troubles common to more complicated lamps. Instead of the carbons being placed one above the other, as in the ordinary arc lamps, they are placed at such an angle that they form a V, the arc forming at the lower end. All of the light is directed downward, and

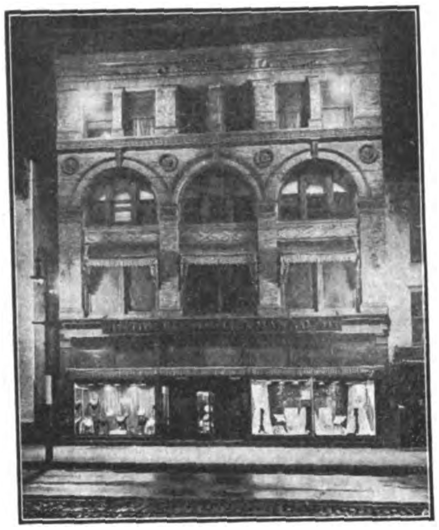


FIG. 1.—BUILDING ILLUMINATION WITH G.-I. FLAME ARC LAMPS.

the absence of any obstruction below the arc prevents shadows being formed. The carbons are fed in such a manner that flickering is prevented and it is impossible for one of them to slide past the other and cause the lamp to go out. Every part of the mechanism is accessible when the

FIG. 2.—G.-I. FLAME ARC LAMP.

casing is lowered. As regards efficiency, the company states that this type of lamp takes less power per unit of illumination than any other illuminant in commercial use.

In designing the lamp special attention has been paid to its external appearance. The shell is made of copper or steel and finished in antique copper or bright japan. The globe is not held by the wire network, but is securely fastened by a flange and ring at the top, the net being retained to prevent the glass from falling should the globe be broken. The entire length of the lamp is only thirty-one inches.

These lamps operate satisfactorily either in series or in multiple on alternating or direct-current circuit and will burn any approved make of flame carbons now on the market.

Proposed Car-Lighting Combination.

An effort is being made, it is stated, to consolidate the United States Light and Heating Company, which was formed to manufacture electric-lighting apparatus for passenger trains, with other concerns doing a similar business. The New York Stock Exchange house of Hooley, Learnard & Company is interested in the proposed consolidation, and is reported to be now engaged in obtaining options on a controlling interest in the United States Light and Heating Company.

About two years ago this company passed under the control of interests identified with the New York Air Brake Company, Charles A. Starbuck, president of that company, becoming president of the United States Light and Heating Company. About the time that Mr. Starbuck was elected president of the United States Light and Heating Company, C. H. Chaffee, now assistant treasurer of the New York Air Brake Company, was made the lighting company's general manager. At the same time Edwin Hawley was named as vice-president. Besides these, the list of officers and directors of the company included A. S. Adler, Charles G. Smith, Charles S. Furst, John J. Moore and W. S. Crandell.

The system of lighting in which the United States Light and Heating Company is interested is known as the Moskowitz system, which employs power generated directly from the axle of passenger cars.

In 1903, the year after the company's organization, William J. Arkell was president of the company, and among the directors were Chauncey M. Depew, Joseph Leiter and Leroy W. Baldwin. The capital of the company from $3,000,000, the figure at which it stood in 1903, was increased to $6,000,000, divided into shares of the par value of $10.

Current Electrical News

GREAT BRITAIN.

London, November 20.—It is interesting to note that in the midst of a prolonged controversy over the efficiencies of surface-contact systems in Great Britain, the Lorain system, which is of American origin, stands quite alone in having demonstrated its reliability above all others. The experiment in London with the "GB" surface-contact system has developed a further stage this week in that the London County Council, acting upon the advice of the president of the Institution of Electrical Engineers, has decided to spend $2,500 more in certain amendments to the car equipments. Although Mr. Mordey's report is not to be made public, from what is known there is a strong suspicion that it criticizes the car equipments. It was this portion of the work, which was in the hands of the Council's officers, about which the "GB" surface-contact company complained when it was decided last July temporarily to cease working the line in the Mile End Road. In this same connection, a lively discussion has been going on at Oxford, where the municipal corporation arranged, a few years ago, with another company to install the Dolter surface-contact system. This system is still in operation in Torquay and Hastings, having been supplanted by the overhead-trolley system at Mexborough in Yorkshire, but after having seen the operation at the first two places, the Oxford corporation was not satisfied as to the suitability of the system and has refused to allow it to be installed.

In connection with a proposal for new capital, the London Electrobus Company has issued a statement showing that during the fifteen months of its existence it has created a record in 'bus receipts, its average having been twenty-eight cents per bus-mile, compared with about twenty-four cents on the London tramways and sixteen cents on the petrol buses. The buses are now said to be earning a profit of $2,250 per month, which leaves a considerable margin for dividend after meeting establishment and overhead charges, debenture interest and depreciation. The new capital is to take the form of six per cent debenture stock.

Following the rejection by Parliament of the bulk electricity-supply scheme for London, the committee is now wrestling with the many conflicting interests arising out of the proposal by the Board of Trade that the London County Council shall be constituted the purchasing authority in 1931, in the place of the various borough councils. Today feeling ran so high that the companies threatened to withdraw the bill and so upset all the plans of the Government, but after consultation with the government authorities, the committee chairman said that such a course of procedure would not be allowed.

It is a popular saying that the best way to shelve a matter is to relegate it to a royal commission. The royal commission on London traffic reported several years ago, but so far no action has been taken to put into effect its recommendation that a special traffic board for London should be elected. This week, however, the prime minister has agreed to receive a deputation from the London County Council on the question. It is of interest to note that since the royal commission on London traffic concluded its sittings, twenty-six and one-half miles of new tube railways have been opened, eighty miles of new electric tramways have been constructed in the outer area and twenty-eight and one-half miles in the county of London; electric traction has been substituted for steam traction on sixty-eight miles of railway, and the northern and southern tramway systems have been linked; and all without a guiding authority to see that there is no waste in the duplication of means of transit, etc.

Systems of charging for electric supply are exercising the minds of engineers in this country to a considerable extent, especially since it has become to be regarded as part of an electric-supply engineers' training that he should have the commercial instinct developed to an even greater degree than his engineering capabilities. The reverse was the case until comparatively recently. So important is this matter regarded, that the Institution of Electrical Engineers, although it devoted a large portion of its time last session to the subject, is opening its new session next week with a paper on a similar subject. G.

EASTERN CANADA.

Ottawa, November 28.—The town of Pembroke, Ont., has passed a by-law providing for the installation of electric pumps for the waterworks system of the town.

The gross earnings of the Shawinigan Water and Power Company for the ten months of the current fiscal year have increased about seventeen per cent, the total for that period being $563,679, as compared with $476,844 for the corresponding period of last year.

The English interests which contemplate putting through the Mexican Power Company's lease to the Mexico Tramway Company over the heads of the directors of the former company, are overwhelmingly in control of the power company and have English proxies, it is said, for no less than 100,000 shares out of 160,000 shares.

Announcement has been definitely made that a merger of electrical interests has been consummated in London, England, whereby Mr. William MacKenzie secures control of the Toronto Electric Light Company, which will consolidate that company with the Electrical Development Company and the Toronto & Niagara Power Company.

The Canadian Postmaster-General, Hon. Rudolph Lemieux, is in London, England, continuing his inquiries regarding a state-owned Atlantic cable. Mr. Lemieux does not admit or deny that he possesses cabinet authority to complete a bargain with the British and Australian Governments, but he says the idea of a state-owned cable is much approved on both sides of politics and among the press, and there is no question that it would also prove a financial success. The minister is also inquiring about government ownership of inland telegraph service in England.

During the first part of December work will be commenced on the building of the proposed bridge across the Niagara River, of the Trans-Niagara Bridge Company. With the completion of this bridge, the International Railway, the Niagara, St. Catherines & Toronto Railway, and the Hamilton, Grimsby & Beamsville Railway companies will be consolidated and the broken links in the trolley system between Niagara Falls and Toronto completed. The new bridge will be exclusively for electric-railway traffic.

A couple of years ago tests were made of electric smelting of iron at Sault Ste. Marie by the Dominion government. As soon as the results of these experiments appeared, a Swedish firm of ironmasters began constructing furnaces, and after two years seems to have achieved success. The furnace at Dumnarfvet was to be started on December 1. Dr. Haanel, the Canadian Government's expert, had been invited to be present and recently left for Sweden to report upon the matter. It is learned that the new furnace is a great advance upon previous efforts. It will use 800 horsepower instead of 250 horsepower employed at the "Soo" tests. The cost of the product under the Swedish process will be only $12 a ton. With the electric process ore with the admixture of two-and-one-half per cent of sulphur can be handled. W.

WESTERN CANADA.

WINNIPEG, NOVEMBER 28.—Although the civic electric street-car system in Edmonton, Alb., has been in operation for less than a month the people are already drawing up a petition for cars to be run on Sundays. At the last session of the Alberta Legislature an act was passed prohibiting the operation of street-railway systems on the Sabbath, despite the fact there was not then a street-railway system in the whole province. An effort will be made to have this law repealed.

Troubles are not coming singly at Port Arthur, Ont., as far as the civic electrical interests are concerned. Last week the street-car controversy was brought to a climax when the system was seized by the sheriff and handed over to a joint commission for operation while the matter is being thrashed out in the courts. The feature for this week is the announcement that the Kaministiquia Power Company, a corporation from the sister city of Fort William, will compel Port Arthur to live up to the contract for the supplying by the company of electrical power, which contract has been canceled by the city on the grounds that the company was using the contract as a leverage with the Ontario Government to obtain power privileges at Dog Lake Falls, where the city is also seeking power privileges.

The ratepayers of the municipality of Saskatchewan, Man., will shortly vote on the question of installing a municipal telephone system. The two adjoining municipalities have systems and it is practically certain that the Saskatchewan municipality will also build a system. Address Councilor John Hunter, Rapid City, Man.

J. L. Nelson, of Winnipeg, has received the contract to supply the Manitoba Telephone Commission with 25,000 telephone poles, which will be delivered during the present winter.

The British Columbia Electric Street Railroad Company will build twenty-four cars at its New Westminster shops, having large platforms that can be fitted up as pay-as-you-enter cars if the system proves successful locally. R. H. Sperling, Vancouver, B. C., is general superintendent of the company.

Tenders are being called by the city of Winnipeg, Man., until December 28 for various work in connection with the civic power plant at Lac du Bonnet. Tenders are being asked for the general work at the power site; the erection of the transmission line from the power site to Winnipeg, a distance of approximately 66.5 miles; the necessary steel towers, and electric transmission cables. Plans and specifications of these works, also forms of tender, may be obtained at the office of the Power Engineer, Carnegie Library Building, Winnipeg, Man., and also at the office of Smith, Kerry & Chace, consulting engineers, Confederation Life Building, Toronto. In discussing the proposed work C. B. Smith, the expert retained by Winnipeg, has announced the plant will be in operation during 1910 if progress is made as proposed.

At a recent meeting of the City Council of Fernie, B. C., it was decided to call for tenders for a 260-horsepower gas-producer plant providing satisfactory arrangements can be made with the Crow's Nest Pass Electric Light and Power Company. Tenders are now being called under these conditions until noon, December 15, and are receivable by A. A. Sharley, acting city clerk, who can also show plans and specifications.

Tenders will be received by Magnus Peterson, secretary of the civic board of control, until February 22, for the supply and erection of a turbine pump and motor for the city water works. Plans and specifications may be seen at the office of H. N. Ruttan, city engineer, Winnipeg, Man.

At Saskatoon a committee has been appointed consisting of R. Smith, M. Mansell and several others, to petition the government to construct telephone lines along the railways both east and west from that city. R.

At Hedley, B. C., the Hedley Power and Development Company has been organized to furnish electricity to a number of the mines in the neighborhood. L. H. Patton has been elected secretary of the concern and 2,000 inches on the Similkameen River has been applied for and a power site selected. Active construction will be commenced as soon as the water rights are granted.

The City Council of Victoria, B. C., is seeking rights from the Provincial Government to develop and distribute electric power, and if these rights are granted will enter into competition with the British Columbia Electric Company.

The ratepayers of McLeod, Alb., will shortly vote on a by-law to raise $35,000 by the sale of debentures for enlarging the civic electric-light and power plant. To date this plant has met all demands, but owing to the rapid growth of the city enlargement is necessary. These debentures will be repayable during a period of forty years. Address E. F. Brown, secretary-treasurer.

IMPORTANT DEVELOPMENTS.

TWENTY-FIVE-YEAR CONTRACT FOR 25,000 HORSEPOWER CLOSED BY ST. PAUL RAILROAD—The Chicago, Milwaukee & St. Paul Railway Company has closed a contract with the Great Falls Water Power Company, of Helena, Mont., for the supply of 25,000 horsepower for twenty-five years. C.

CHICAGO AND MILWAUKEE ELECTRIC RAILROAD MORTGAGE TO BE FORECLOSED—On November 27 the attorney representing the bondholders' committee of the Chicago and Milwaukee Electric Railroad filed a bill in the United States Circuit Court at Chicago asking for the foreclosure of the mortgage on the Illinois section of the road. A similar suit relating to the Wisconsin corporation was filed a week previously. It is believed that the system will be bought up by the bondholders at the foreclosure sale and a reorganization effected that will terminate the financial entanglements of the properties.

CHICAGO CITY RAILWAY COMPLETES ITS BOND ISSUE—The Chicago City Railway Company has sold $6,000,000 of its first mortgage five per cent bonds to the Illinois Trust and Savings Bank. With the previous issues of $12,000,000 this completes the $18,000,000 of bonds authorized for rehabilitation purposes by the new traction settlement ordinance. The expenditures permitted from the proceeds of the bond issue are all carefully checked by the Board of Supervising Engineers. Considerably over half of the rehabilitation work assigned to the company has been completed in less than half the specified time.

SULTAN OF TURKEY REMOVES BAN ON TELEPHONES IN EMPIRE—The Turkish government is looking for someone who will undertake the installation of a complete telephone system throughout the empire, according to a communication sent to the Department of Commerce and Labor by Vice-Consul General Heizeer, from Constantinople. Soon after the establishment of a constitutional government in the Ottoman empire, an order was issued abolishing the former regulations prohibiting the telephone. Now the Turkish government announces that it will receive bids on a complete telephone concession for the entire country during the month of December.

AMERICAN TELEPHONE AND TELEGRAPH COMPANY SELLS $50,000,000 BONDS—The American Telephone and Telegraph Company has sold $50,000,000 of its four per cent convertible gold bonds to a syndicate consisting of J. P. Morgan & Company; Kuhn, Loeb & Company; Kidder, Peabody & Company, and Baring Bros. & Company, Limited, of London. These bonds are identical with the $100,000,000 issue sold to the same bankers in 1906. This sale completes the authorized issue of $150,000,000 of these bonds and fully finances the company for the years 1909 and 1910, including provision for the $6,000,000 Western Telephone and Telegraph notes, due in May, 1909, and $25,000,000 American Telephone and Telegraph notes, due in January, 1910.

BEGIN SURVEYS FOR PHILADELPHIA-CAMDEN TUNNELS UNDER DELAWARE RIVER—Actual work on the tunnels under the Delaware River to connect Camden, N. J., with Philadelphia has been begun, a corps of civil engineers having commenced the surveys on both shores. This was announced by W. A. Stern, of Stern & Silverman, the railroad contractors, who will have charge of the work, the cost of which is conservatively estimated at $7,500,000, but which may aggregate nearly twice that amount before the task is completed. The method of construction will follow very closely that used by the Pennsylvania Railroad in building its tunnels under the North and East rivers in New York. They will be excavated by the "shield" method, which involves the forcing of an immense steel section ahead of the big force of men that will be required in removing the earth.

BOSTON'S NEW MILE OF SUBWAY COSTING $10,000,000 TO BE OPENED—Excellent progress is being made on the new subway under Washington Street, and the Boston Elevated Company expected to be running cars in the tunnel before December 1. The length of the new subway is 5,676 feet, and the construction and equipment have cost over $10,000,000. The platforms are 350 feet long, and the addition to the road is expected to increase the carrying capacity 175 per cent. The new tunnel has been made absolutely fireproof. The lighting is by incandescent lamps, arranged behind beams of the arched ceilings. To insure a perfect supply of fresh air in the tunnel there are four fan chambers, each fan being capable of exhausting 25,000 cubic feet of air per minute. The foul air is drawn out in the tunnel between stations, through ducts constructed in the concrete ceilings. The fresh air enters at the several stations, the entrances of which are open save for an ornamental grille work.

TELEPHONE AND TELEGRAPH.

McCALLSBURG, IOWA—A new switchboard will be installed in the telephone building at McCallsburg. C.

OAKWOOD, OKLA.—The Oakwood Telephone Company has been incorporated with a capital stock of $750. P.

MERCEDES, TEX.—The Mercedes Telephone Company has been incorporated with a capital stock of $1,000. P.

IOWA CITY, IOWA—The Johnson County Telephone Company contemplates spending $35,000 on improvements. P.

BARTLETT, TEX.—The Bartlett & Donahoe Telephone Company has been incorporated with a capital stock of $300. P.

KINGSLEY, IOWA—The directors of the Kingsley Telephone Company have decided to install a new switchboard in the exchange at Kingsley. C.

FRANKLIN, PA.—The Bell Telephone exchange at Franklin was destroyed by fire, entailing a loss of $35,000, part of which is covered by insurance.

OLYMPIA, WASH.—The United Wireless Company is arranging equipment for a receiving station, using the dome of the state capitol as a mast.

OLYMPIA, WASH.—The Uniontown Telephone Company, of Uniontown, has been incorporated with a capital stock of $5,000 by Lambert Taufen, W. W. Miller and George A. Dressel.

PORTLAND, ME.—All the property rights, franchises, privileges and appurtenances of the Northeastern Telephone Company will be sold at public auction, December 16, by Frank E. Ebersole, as special master, by a decree of foreclosure.

OMAHA, NEB.—The Independent Telephone Company is contemplating putting in $1,000,000 worth of extensions and improvements. It is the intention to develop exchanges simultaneously at Benson, Florence, Dundee and South Omaha.

FOND DU LAC, WIS.—Articles of incorporation have been taken out for the organization of the Eldorado & Friendship Telephone Company, the capital stock being $5,000. The incorporators are: John Reilly, W. H. Keyes, W. C. Pay, L. G. Barnes and W. T. Reilly.

VALLEJO, CAL.—The new switchboard recently installed by the Western Electric Company, of Chicago, in the exchange of the Pacific Telephone and Telegraph Company, at Vallejo, was successfully cut over recently, and the town has now one of the most modern exchanges in the country.

ROCHESTER, N. Y.—Reorganization and merging of all seven Bell telephone companies operating in New York state is under way by the American Telegraph and Telephone Company, and on or about January 1 the merger will become a fact. A holding company will be the vehicle for carrying the control of the companies. The total capitalization of the seven companies is now $89,585,200.

PERSONAL MENTION.

MR. JOHN T. MORRIS, of Columbus, Ohio, has been engaged by the Canal Dover Board of Public Service as designing engineer and superintendent of construction for the municipal electric light plant which will be erected in that city.

MR. GRANT W. SPEAR, who for many years has been vice-president of the Dearborn Drug and Chemical Works at Chicago, has taken charge of the general eastern offices of the company at 299 Broadway, New York city, as vice-president and eastern manager.

MR. JOHN MUSTARD, of the Wagner Electric Manufacturing Company, has been appointed assistant manager of sales for the territory inclusive and east of Pittsburg, with headquarters in Philadelphia. Mr. Mustard has been with the company as district manager at Philadelphia for the past fifteen years.

MR. MELDON H. MERRILL, who, as salesman for the Westinghouse Electric and Manufacturing Company, has been active for some years past in promoting the introduction of electric drive among the textile mills in New England, has recently resigned his position with that company, taking up similar work in connection with the Boston office of the Allis-Chalmers Company.

MR. THOMAS GRAHAM GRIER, of Chicago, president of the Grier Company, manufacturers' agent, and author of the book "On the Canal Zone," recently favorably reviewed in this paper, delivered an illustrated lecture on "The Panama Canal and Life on the Canal Zone," before an audience at the auditorium of the Hyde Park Young Men's Christian Association, Chicago, Thanksgiving night.

MR. GEORGE A. POWELL, of Winnipeg, who has been associated with the Packard Electric Company, Limited, of St. Catharines, Ont., for the last fifteen years, has severed his connections with that company. He has started business for himself in the electrical line as commission broker, with offices in the Union Bank Building, Winnipeg, Man. He will continue to represent, among other agencies, the Eugene F. Phillips Electrical Works, Limited, of Montreal, well-known makers of bare and insulated copper wires and cables.

MR. J. R. GORDON has accepted the position of manager of power apparatus sales for the Western Electric Company for its southern territory. He will continue to make his home in Atlanta, Ga. He resigned a month ago from his position of manager in the Southern States for the Westinghouse Electric and Manufacturing Company. Mr. Gordon is known throughout the country as a pioneer in the electrical field, having been associated with those who organized and operated the first of the Edison plants. For many years he has been a prominent member of the American Institute of Electrical Engineers and the American Society of Mechanical Engineers.

MR. KARL LAURELL, a draftsman at the Lynn, Mass., works of the General Electric Company, has sailed for Sweden, where he will soon begin duties as general superintendent of the Stockholm Electric Supply Company. Mr. Laurell has been in this country for less than two years, and during that time has been connected with the General Electric Company, where he has been studying American systems in the production of electrical supplies. He is twenty-six years of age and was born in Upsala, Sweden. Laurell attended the Royal College in Stockholm, where he took a thorough electrical course, and after finishing came to this country for practical experience.

MR. W. B. McVICKER, resigning as vice-president and eastern manager of the Dearborn Drug and Chemical Works, with which he has been connected for many years, has incorporated the W. B. McVicker Company, with offices in the United States Realty Building, 115 Broadway, New York. A new and complete laboratory and factory is being built to have exceptional facilities for general analytical work and the manufacture of high-class products, and a specialty will be made of high-grade lubricants and scientific preparations for treating boiler feed-waters and hydraulic systems. The personnel of the company includes Charles M. Eddy, Albert E. Carpenter, Joseph F. Hammill, William J. Schatz, G. Frank Duemler and Frank J. Zink.

ELECTRIC LIGHTING.

WOMBLE, ARK.—The Bear State Lumber Company will install an electric-light plant at Womble. P.

ALVIN, TEX.—E. B. Hill has been granted a twenty-five-year franchise for an electric-light plant.

SEATTLE, WASH.—The Coast Lighting Company has been incorporated with a capital stock of $25,000.

HINCKLEY, MINN.—The dam of the Hinckley Electric Company has gone out entailing a loss of $1,000. C.

ROCHESTER, MINN.—Rochester contemplates issuing bonds for from $50,000 to $75,000 for a lighting plant. P.

RUTHERFORD, N. J.—The Borough Council has passed a resolution to advertise for bids for street lighting.

MERCEDES, TEX.—The Mercedes Electric Light Company has been incorporated with a capital stock of $2,000.

MONTEREY, TENN.—Monterey is to have an electric-light plant and bids are now being taken for the contract.

VAN BUREN, ARK.—W. R. Petty, of Pine Bluff, Ark., contemplates establishing an electric-light plant in Van Buren. P.

YORK, PA.—The Peach Bottom Electric Transmission Company, of York, has been incorporated with a capital of $5,000.

SABINAL, TEX.—The Sabinal Water and Ice Company has increased its capital stock and will build an electric-light plant. P.

WEATHERFORD, OKLA.—Twenty-five thousand dollars in bonds has been voted for the construction of an electric-light plant.

BROWNS VALLEY, MINN.—It is proposed to dam the Little Minnesota River near Browns Valley, securing power to operate an electric-light plant. C.

FAIRVIEW, OKLA.—Fairview will install an electric-light plant which will cost $10,000. The plant may be finally owned by the city on an option.

JOLIET, MONT.—Work is about to commence on an electric-light and gravity water system, which Norman S. Poole, engineer, has been promoting, at Joliet. C.

ESCANABA, MICH.—A second power dam, capable of furnishing 25,000 horsepower, will shortly be constructed across the Escanaba River near Groos, Mich. C.

NEW CASTLE, IND.—The Maxwell-Briscoe Motor Company will erect and install a combined water and electric-light plant for its large factory at New Castle. S.

KANSAS CITY, MO.—The main power plant of Swift & Co.'s packing house was destroyed by fire shortly before midnight, November 27. The loss was $40,000.

MONDOVI, WIS.—The Mondovi Light and Power Company has been incorporated with a capital of $35,000 to own and manage two mills and an electric-light plant.

MOUNT AYR, IOWA—The Mount Ayr Light and Power Company, of which W. Jackson Bell is secretary and general manager, has been incorporated with a capital of $20,000. C.

ST. CLOUD, MINN.—The Union Power Company expects to have its power station at the east end of the mill canal at St. Cloud completed and the water turned on December 15. C.

LOUISVILLE, KY.—The Kern Electric Company has been incorporated in Daviess County with a capital of $6,000. W. J. Kern, E. L. Holbrook and C. G. Kern are the incorporators.

DANVILLE, IND.—The Danville Light, Heat and Power Company has increased its capital stock from $36,000 to $100,000. It is proposed to improve and enlarge the plant and install new machinery. S.

LAPORTE, IND.—The managers of the electric plant of the Laporte Public Utility Company, which was recently destroyed by fire, have given out that the plant will be rebuilt and new machinery installed at once. Otto Wettstein is secretary and manager.

REDWOOD FALLS, MINN.—R. F. Wherland is working on a scheme to develop the waterpower of Redwood Falls, Minn. A stock company with a capital of $100,000 is being organized for the purpose. C.

JEFFERSON CITY, MO.—The American Light and Power Company, of Union, has been incorporated with a capital stock of $10,000, by W. W. McCurdy, C. P. Reinhard, L. W. McCurdy and others.

TONOPAH, NEV.—The Rhyolite Electric Company has filed letters of incorporation, with W. D. Hatton, C. A. Stoible and M. J. Hill, all of Goldfield, as directors. The capital stock is placed at $100,000.

BELLE FOURCHE, S. D.—The Belle Fourche Electric Light, Heat and Power Company will string a line from the Redwater plant of the Black Hills Traction Company to furnish electric light for the town.

ALVIN, TEX.—At a meeting of the City Council a twenty-five year franchise was granted to E. B. Hill for establishing an electric-light plant for the city. The conditions are that he complete it in twelve months.

JOPLIN, MO.—Henry L. Doherty & Co. have purchased the Consolidated Light, Power and Ice Company, of Joplin, and the Galena Light and Power Company, of Galena, Kan., and will erect a central power station. P.

WINNIPEG, MAN.—The City Council of Winnipeg will go ahead with the construction of the power plant on the rapids of the Winnipeg River. The contract will be let at once calling for an expenditure of $1,500,000. C.

VILLA GROVE, ILL.—The Villa Grove Electric Company has been incorporated with a capital stock of $15,000, for the purpose of operating electric-light and power plants. The incorporators are V. M. Elmore, C. W. Hagerman and C. B. Kennington.

COLUMBUS, OHIO—Articles of agreement for the consolidation of the Warren Gas Light and the Hyde Electric Companies, both of Warren, have been filed. The new concern will be known as the Hyde Electric and Gas Company, and the capital stock is fixed at $350,000.

SEATTLE, WASH.—An increase from $500,000 to $800,000 in electric-light bonds for the city of Seattle has been recommended by the City Council's finance committee. It will be submitted to popular vote on December 29. The smaller amount had been previously voted.

BOISE, IDAHO—Articles of incorporation of the Slate Creek Electric Light and Power Company have been filed. The company is capitalized at $3,000,000, and will do a general electric-light and power business in Wallace, Idaho, building a plant to operate a big water right in the Slate Creek district.

LINTON, IND.—The City Council of Linton is in the market for the purchase of $15,000 worth of new equipment for the electric-light plant. The proposition to improve the plant was opposed by many citizens who claim that after eight years of municipal electric-light service the plan has proved a failure. S.

GENEVA, N. Y.—The Geneva-Seneca Electric Company has begun the erection of a new power station. The company intends to expend approximately $150,000 in betterments, of which $75,000 will be utilized in the construction and equipment of a new power plant and the balance upon transmission improvements.

LUDINGTON, MICH.—A. P. Carr and E. J. Quirk are promoters of a company to build an immense concrete and pile dam across the Pere Marquette River in Custer township, to use the waterpower for the production of electricity. A power house will be built and three hydraulic turbines, each capable of generating 500 horsepower, installed.

HAGERSTOWN, MD.—Clarence E. Easterday, Orville E. Shifler and H. L. Moser, composing the Antietam Electric Light and Power Company, are constructing a $13,000 electric plant. The company has contracted to furnish light to the municipality of Boonsboro and is now negotiating to light the towns of Sharpsburg and Keedysville.

OGDEN, UTAH—The Chamber of Commerce of Ogden has gone on record as favoring a municipal electric-lighting plant, and urged the immediate action of the Council in utilizing water owned by the city for that purpose. A resolution was adopted requesting the Council to exercise its rights and perform its duty in establishing electric-light rates in Ogden.

FINDLAY, OHIO—Meter rates have been dispensed with for all commercial lighting at Findlay. Prices have also been reduced from ten to eight cents per kilowatt-hour. While the City Council is advertising for bids for lighting the city after the expiration of present contracts, it is thought that under the concessions named a new contract will be made with the present concern. H.

LYNCHBURG, VA.—A modern electric plant for lighting the country residence, barn, and other buildings on the Nelson County estate of Thomas F. Ryan has been put into commission. "Oak Ridge" is one of the finest estates in Virginia, and is one of the few rural homes in the state to be lighted by electricity developed in a private plant. The power plant cost Mr. Ryan $25,000, it is reported.

SANTA FE, N. M.—Incorporation papers have been filed by the El Paso Power and Light Company, with headquarters at Alamogordo, Otero County. The capitalization is $5,000. The incorporators and directors are J. L. Lawson, A. F. Menger and H. J. Stacey of Alamogordo. The company is to use the power from the Penasco River to generate electricity to be carried to El Paso.

LIMA, OHIO—The latest development in the municipal lighting-plant fight at Lima is the filing of an injunction suit by City Solicitor Rogers, who asks that the legislation under which the work is proceeding be declared illegal and the work be stopped until the matter can be determined by the courts. In the meantime the board of public service is going on with the erection of the new plant. H.

BUCYRUS, OHIO—On the first of March the present city-lighting contract expires and an injunction has been granted against the city restraining it from issuing $80,000 bonds, recently authorized by vote of the people, for the purpose of erecting a municipal lighting plant. Eight bids were tendered and as they were about to be opened the injunction was made on the application of T. M. Droleabaugh, a taxpayer. H.

AUGUSTA, GA.—The contract for the construction of a dam which will also serve as a bridge across the Savannah River at Price's Island, twenty miles above Augusta, has been awarded. The work will be commenced in December and will require about one year to complete. The dam, which will cost about $3,500,000, will be thirty feet high and will furnish 15,000 horsepower, which will be transmitted to Augusta to a substation.

SALISBURY, N. C.—It is reported that work will be resumed on the big $10,000,000 water and electric plant at Whitney, on the Yadkin River, thirty miles from Salisbury. Plans are being formulated for raising $2,000,000 for the completion of the plant, which will furnish electric power to a vast area in North Carolina. More than $5,000,000 has already been spent on the plant. Operations ceased on account of a receivership several months ago.

CHARLOTTE, N. C.—The Westinghouse Electric and Manufacturing Company has secured the largest contract for transformers ever made with an electric manufacturing company. This contract, awarded by the Southern Power Company of Charlotte, N. C., calls for transformers aggregating a capacity of 93,000 kilowatts. The apparatus will be used on the transmission line between Charlotte, Greensboro and Greenville, covering an area of 240 miles.

SAN FRANCISCO, CAL.—Another large hydroelectric power project is now in prospect for central California. It has been announced that the extensive water right properties on the American and Cosumnes rivers, owned by W. H. Tevis and recently offered to the city for a municipal water supply, are to be developed for the production of electric power. C. N. Beal, who is associated with Mr. Tevis in the project, says engineers are still at work on the matter. The properties have been released from the contract with the Bay Cities Company, and will be developed for power. Mr. Beal also states that a market for the power has been secured in advance.

ALBERTVILLE, ALA.—The Sand Mountain Electric Company, composed of Albertville business men, has been organized and active operations will begin toward the erection and installation of a plant to light the town of Albertville. E. O. McCord is president and general manager of the company, which owns the Short Creek Falls (four miles from town), valuable real estate in Albertville and has a twenty-five-year franchise and contract for lighting Albertville.

BRIDGEWATER, MASS.—The Edison Electric Illuminating Company has purchased the plant of the Bridgewater Electric Company and will soon begin extensive improvements, planning to give the town of Bridgewater twenty-four-hour service. A transmission line will be built from East Bridgewater to Bridgewater. The Edison company plans to install arc and incandescent lights along the streets and to increase the electric-power business in the town.

WINDSOR, ONT.—At the approaching municipal elections in Windsor, ratepayers will probably be asked to vote on a by-law to authorize the expenditure of about $25,000 or $30,000 in order to provide a practically new lighting plant for the city. As an alternative proposition, it is likely that they will be given an opportunity to express themselves on the project of purchasing Niagara power from the Hydroelectric Commission of the Ontario Government under the government scheme.

ANACONDA, MONT.—The Great Falls Water Power and Townsite Company announces it is developing approximately 30,000 horsepower now, and will probably add about 50,000 horsepower in other developments later on. The waterpowers at Great Falls were purchased, it is said, in the firm belief that the time is very near when the railroads operating over the mountains must avail themselves of the cheap power furnished by the waterpowers of the state in moving their trains over the mountain grades.

WALLACE, IDAHO.—The Slate Creek Electric Light and Power Company, which is endeavoring to secure a charter from the city for a period of fifty years, has filed articles of incorporation and is capitalized at $3,000,000. The company is to do a general electric-light and power business, the intention being to build a power house in the Slate Creek district, sixteen miles from Wallace. The incorporators are D. L. Hopkins, Thomas McGowan George W. Baldwin, Jesse Freeman and William Sites. The City Council is said to be favorably inclined toward the new company.

SAGINAW, MICH.—The Eastern Michigan Power Company is seeking to supply Saginaw and Bay City and adjacent territory with electric current for light and power. This company is developing the Au Sable River from Au Sable to Milo, a distance of about 100 miles. The total amount of power that can be developed is declared to be approximately 50,000 horsepower, and this is to be obtained by the erection of ten or twelve dams, ranging in height from twenty-five to forty feet, located at different points along the river, according to the fall and local conditions. The total outlay for the completion of the work will be several millions of dollars. If the franchises are granted the company expects to deliver current in these markets within a year to eighteen months.

TACOMA, WASH.—A report of a civil engineer, H. A. Whitney, on his investigation of the power site offered by Henry Bucey on the west side of Hood canal, shows the inadvisability of utilizing the water from the Dosewallips and Dickabuch rivers for power purposes by means of a dam placed at the foot of a canyon. "The minimum head which the dam will give, if placed where proposed, is 200 feet," says the report. "The flow of the Dosewallips River is 214 cubic feet per second, and of the Dickabuch 114 feet per second. If the city could utilize the rivers to their capacity, it would require an available head of 320 feet in each stream to get sufficient power at this time of the year. It is not possible at the present stage of the water to develop 10,000 horsepower, as proposed by the city council. About 4,000 horsepower is all that could be secured."

ELECTRIC RAILWAYS.

EAU CLAIRE, WIS.—There is a project on foot for connecting Eau Claire and Osseo by an electric railway twenty miles long.

WEBSTER CITY, IOWA—An interurban road between Webster City and Clarion, Iowa, is projected. It is expected that the $300,000 necessary to construct the road can be raised without resorting to bonding the property. C.

DES MOINES, IOWA—The company bonding the Des Moines & Sioux City Electric Railway Company insists that the road be an air line between Des Moines and Sioux City, and it be built to carry 100-ton electric freight locomotives. C.

NASHVILLE, IND.—Joseph Irwin, of the Indianapolis, Columbus & Southern, is making plans to build an electric line from Columbus to Bloomington, via Nashville. Inquiries have been made in regard to franchises and right-of-way. S.

BALTIMORE, MD.—Construction work is nearly completed on the new Baltimore, Halethorpe & Elkridge Electric Railway. The road, which is three and a half miles long, runs from the terminus of the Wilkens Avenue line of the United Railways to Halethorpe.

WARSAW, IND.—Representatives of the Murdock traction system have entered into an arrangement with officials of the Winona Interurban Railway and the Northern Indiana Railway, providing for running cars from Indianapolis to South Bend. The service will be put into effect as soon as the gap between Warsaw and Peru is closed. S.

CRAWFORDSVILLE, IND.—Citizens of Crawfordsville who are interested, announce that the Kokomo, Frankfort & Terre Haute Traction line will be built during the next year, and work will begin on the road at two or more places along the route. The company has placed the bonds on sale and there is every indication that these will find a ready sale. S.

RALEIGH, N. C.—The Burgrahaw Interurban Company, organized with a capital stock of $500,000, proposes building and operating an electric railway between Burlington, Graham, Haw River and other points near Burlington. The incorporators are: C. E. W. Tenney, of New York; F. S. Jones, of Nashville, Tenn., and E. S. W. Dameron, of Burlington.

OTTUMWA, IOWA—The leading business men of Ottumwa and representatives from nearby towns, which are anxious to get interurban roads, attended a meeting of the Ottumwa Commercial Association when the matter was discussed with H. W. Garner, manager of the Oskaloosa Traction and Light Company and the Oskaloosa & Buxton Interurban Company. C.

CAIRO, ILL.—The Cairo City Council has granted a fifty-year interurban franchise and a twenty-year street railway franchise to the McKinley syndicate. The syndicate has already bought the local electric street railway, electric-light plant and the Cairo City Gas Company. An interurban line will be built to connect Cairo with Mounds, Mound City and Villa Ridge, and will later go on to St. Louis.

BELLINGHAM, WASH.—To supply power for the proposed Skagit Interurban Railway, the Stone & Webster interests will double the capacity of the Nooksack power plant. The improvement will cost $250,000, a sum equal to the cost of the plant, which was completed two years ago. When the survey for the interurban right-of-way was made, all streams in Skagit County were carefully examined, but suitable waterpower was not found.

BELOIT, WIS.—Following the "tag-day" movement the City Federation of Women's Clubs of Beloit, Wis., ran the city street cars Saturday, November 21, and the fares collected were added to the fund from the tags to swell the total for the school children of Beloit. The Traction Company made the women the offer, which was promptly accepted, and everyone who patronized the cars—and everyone did—paid fares to the women of the federation, while the regular conductor stood by, attending to stopping and starting the cars. The traction company received no returns from the day's operation except the grateful appreciation of the citizens.

LAFAYETTE, IND.—It is announced that the Fort Wayne & Wabash Valley Traction Company will, during the next year, extend its line from Lafayette to Danville, Ill., where it will make connection with the McKinley Traction System, reaching many towns and cities in Illinois and including St. Louis, Mo. The new extension when built will touch West Point, Attica, Covington, Williamsport and other small towns in a territory thickly settled. S.

BOSTON, MASS.—The Railroad Commission has approved the terms of consolidation of the Middlesex & Boston, the Westboro & Hopkinton and the Natick & Cochituate Street Railway Companies, as the Middlesex & Boston Street Railway Company. The commission also approved an increase in stock of the Middlesex & Boston company to not exceeding $140,000 for carrying out the consolidation and in exchange share for share of the companies above named.

JOLIET, ILL.—The Secretary of State has issued a license to incorporate to the Chicago, Joliet & Western Interurban Railway Company. The principal office is Chicago and the capital stock is nominally $10,000. It is proposed to construct a railroad from the city of Chicago southwest through the counties of Cook, Dupage and Will to Joliet, and west to the counties of Kendall, Grundy and La Salle. The incorporators and first board of directors are headed by G. Fox, of Chicago.

STOCKTON, CAL.—A large meeting of land owners and business men from both Stanislaus and San Joaquin counties has been held at Escalon to further the immediate construction of an electric railway to run adjacent to the French Camp road to Escalon, thence to Modesto, with a main line to Oakdale. J. L. Craig, chairman of the meeting, delivered a convincing address covering the desirability, as well as the necessity to the future welfare of the district, of the construction of the railway.

DENVER, COLO.—Articles of incorporation for the Crags and Canon Railway Company have been filed by George F. Keller, recently of Fort Wayne, Ind., representing capitalists of that city; L. B. Bradley, recently of Chicago; G. A. Brink, D. C. Nevin and N. S. Williams, of this city. The company is capitalized at $300,000 and is incorporated to build a standard-gauge railway from the town of Crags on the Moffat Road to Eldorado Springs, thence to Boulder. Mr. Bradley, who is an electrical engineer, has been in Colorado for the past year, devoting most of his time to surveys of the proposed railway. The final survey from Crags to Eldorado Springs, with a maximum grade of four per cent, has been established and the line from Eldorado Springs to Boulder will not exceed a maximum of one per cent. The plan of the incorporators is to build to Eldorado Springs, if possible, in time for the tourist travel of next season, and when the line is completed to Boulder, it will connect all northern Colorado with the Moffat Road, making a cut-off that will save about sixty miles of travel by way of Denver to reach western points on the Denver & Northwestern Pacific.

OBITUARY.

MR. JAMES E. MURDOCK, head of what is known as the Murdock syndicate of interurban lines in northern Indiana, and one of the wealthiest men in the state, dropped dead in his home in Lafayette, Ind., November 27, at the age of seventy-one years. Mr. Murdock had been a prominent figure in the construction of the lines of the South Bend & Chicago and of the Fort Wayne & Wabash Valley Traction companies, and was president of the Merchants' National Bank of Lafayette at the time of his death, besides retaining his earlier connections with the natural-gas industry in Ohio and Indiana. Mr. Murdock was born in Ireland in 1837, coming to Lafayette when a lad. He started the career which led to his great fortune, by working in a brick yard. Mr. Murdock was not only enterprising in the building up of the great systems of which he was the nominal head, but was also known to be benevolent, never refusing, it is said, to contribute to a worthy cause. S.

ENGINEERING SOCIETIES.

INDIANA ACADEMY OF SCIENCE—The Indiana Academy of Science held its annual session at Purdue University, Lafayette, Ind., beginning November 27. "Deforestation and Its Effects" was the subject of the official address of Prof. Glen Culbertson of Hanover College, president of the body. Following a general inspection of the departments of Purdue University, the evening session was held in the lecture room of the electrical building, where a large audience heard an illustrated lecture and demonstration by Prof. H. T. Plumb, associate professor of electrical engineering at Purdue, on "High-Frequency Currents."
S.

ITHACA SECTION, A. I. E. E.—The second regular meeting of the Ithaca Section, American Institute of Electrical Engineers was held November 19, with 130 members and visitors present. Prof. H. H. Norris gave an experimental demonstration of "Atmospheric Insulator Losses in Transmission Lines." Various corona effects were shown, and by means of wattmeter measurements the corresponding power losses were determined. The sixty-thousand-volt transformer used in these experiments was the one designed and constructed by Prof. H. J. Ryan, and used in his famous experiments. This demonstration was appropriate in view of the recent discussion of Mr. Mershon's Atlantic City paper before the local section. Where such experiments are practicable in the section meetings they go far to arouse interest in the Institute papers.

FORT WAYNE SECTION, AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS—The Fort Wayne Section of the American Institute of Electrical Engineers held a well-attended meeting on November 12, which was preceded by the usual informal dinner. The paper for the evening, "Paralleling of Alternators," presented by J. J. Kline, of the Fort Wayne Electric Works, was followed by a very active discussion, in which many interesting things were brought up. A. L. Hadley spoke at some length on the cross currents which occur in alternators direct-connected to slow-speed gas engines and the difficulty of adjusting the prime movers so as to reduce the cross currents to a minimum. M. J. Kehoe described his experience with some steam turbines direct-connected to alternators, citing a case which had occurred in his plant on frequent occasions, when with two machines running in parallel without apparent cause the machines would suddenly drop their load and the voltage would fall to zero. There seemed to all intents and purposes to be no cause for this on the part of the alternators, but it had occurred on numerous occasions and the makers failed to furnish a suitable explanation of the difficulty. It was suggested that the cross currents and armature reaction might succeed in demagnetizing the poles due to an excessive overload. Mr. Kehoe was asked to furnish further information on this point at the next meeting, although, as he explained, the trouble had been entirely obviated by the adoption of a Tirrill regulator. Owing to the lateness of the hour further discussion was postponed until next meeting. At the next regular meeting E. A. Barnes, superintendent of the Fort Wayne Electric Works, will present a paper, "Choice of Power for Industrial Purposes."

ELECTRICAL SECURITIES.

The general undertone of last week's stock market was firm, although there was considerable irregularity. Some smart rallies were shown, as compared with a week ago, and while trading was less active than previously and largely professional, there was some gain in this direction. The increased buying, however, did little to attract further public participation, and there has been quite a slump in commission business. It is understood that the larger interests are favoring higher prices. There has been no change in the bank situation, except that money rates have worked lower, especially for time funds, with liberal offerings. The indications are that if there is any turn, it will be for an easier market.

Dividends have been declared upon the following electrical securities: Regular semi-annual dividend of $4 per share on the capital stock of the Electric Light and Power Company, of Abington and Rockland, payable January 1 to stock of record December 21. Massachusetts Electric Companies' trustees have voted to resume the dividends on the $20,557,400 preferred stock by a declaration of a dividend of one per cent. The last regular semi-annual dividend on the preferred was paid January 1, 1905. Puget Sound Electric Railway; semi-annual dividend of $3 on the preferred stock, payable January 1 to stock of record December 15. Consolidated Gas Company, of New York; quarterly dividend of one per cent, payable December 15. Chicago Telephone Company; quarterly dividend of two per cent, payable December 31 to holders of record December 23. Mackay Companies; quarterly dividends of one cent on the common and preferred stocks, payable January 2 to holders of record December 12. Michigan State Telephone Company; quarterly dividends of one per cent on the common, payable December 1, and one-and-one-half per cent on the preferred stock, payable February 1.

ELECTRICAL SECURITIES FOR THE WEEK ENDED NOVEMBER 28.

New York:	*Closing.*
Allis-Chalmers common	14⅝
Allis-Chalmers preferred	48½
Brooklyn Rapid Transit	55¼
Consolidated Gas	162½
General Electric	158¾
Interborough-Metropolitan common	14½
Interborough-Metropolitan preferred	35⅛
Kings County Electric	128
Mackay Companies (Postal Telegraph and Cables) common	75¾
Mackay Companies (Postal Telegraph and Cables) preferred	71
Manhattan Elevated	146¼
Metropolitan Street Railway	30
New York & New Jersey Telephone	121
Western Union	71½
Westinghouse Manufacturing Company	91¼

Application has been made to the New York Stock Exchange by the Interborough Rapid Transit Company to list $25,000,000 three-year convertible six per cent notes.

The Consolidated Gas Company announces that more than $13,000,000 of the $20,000,000 outstanding six per cent convertible bonds have been turned in and exchanged for stock.

Current earnings of the Western Union Telegraph Company are reported by official sources as steadily improving, and the figures for the quarter ending December 30 are expected to considerably exceed the last two quarters and the normal earnings of the same period prior to the year 1907. The increase in gross revenue has been seconded by economies in operation and maintenance and has produced a large increase in net.

The New York & New Jersey Telephone Company will offer to stockholders $5,047,000 new stock in the ratio of one share of new for each five of old. The right to subscribe expires January 16, 1909, on which date a payment of fifty per cent must be made. The other fifty per cent is divided into two equal payments on April 6 and July 16, 1909. Right to subscribe accrues to stock of record December 1.

Boston:	*Closing.*
American Telephone and Telegraph	130¾
Edison Electric Illuminating	250
Massachusetts Electric	60
New England Telephone	124½
Western Telephone and Telegraph pref.	75
Philadelphia:	*Closing.*
Electric Company of America	10½
Electric Storage Battery common	43
Electric Storage Battery preferred	43
Philadelphia Electric	11½
Philadelphia Rapid Transit	22⅞
United Gas Improvement	93⅞

November earnings of the Philadelphia Rapid Transit Company, while not as good as those of October, which showed $85,000 increase in gross over last October, are very satisfactory, and will show a large increase over November, 1907. No action has been taken in regard to a new director to succeed George H. Earle.

Chicago:	*Closing.*
Chicago Telephone	129
Commonwealth Edison	104¾
Metropolitan Elevated preferred	42
National Carbon common	80
National Carbon preferred	112

It is announced that Chicago Telephone bonds to the amount of $1,000,000 will be offered to the public.

INDUSTRIAL ITEMS.

THE CAMPBELL-STAGG COMPANY, New York, calls attention by a useful blotter to its "Star" bushings for conduit, which are obtainable at all supply houses.

THE WARNER ARC LAMP COMPANY is erecting a factory at Wilton, Iowa, which when completed will provide employment for more than one hundred men. The plant will have a capacity of 125 finished lamps per day.

WICKES BROTHERS, Saginaw, Mich., machinery manufacturers and dealers, have issued their monthly stock list, dated November 15, listing boilers, engines, dynamos, motors and machinery in stock at their sales warehouses at Saginaw, Pittsburg, New York and Jersey City.

THE AUTOMATIC ELECTRIC COMPANY, Chicago, manufacturer of automatic telephone apparatus, directed the attention of visitors to the Independent Telephone Convention, held at the Auditorium Hotel, Chicago, this week, to its exhibit in Rooms 614 and 616, where some of its latest automatic products were shown.

L'ARGUS DE LA PRESSE, Paris, whose offices were destroyed by fire January 15, announces that it has been completely reorganized and that its documents, collections and special services have been re-established and improved. The new address of the publication is Faubourg Montmartre, 37 Rue Bergere, Paris.

THE METROPOLITAN ELECTRICAL SUPPLY COMPANY, 184 Lake Street, Chicago, is making a specialty of the "Wizard" massage vibrator. The vibrator weighs one and one-fourth pounds, and operates on both alternating and direct current. It is supplied with an aluminum case, maple handle, green silk conductor cord, scalp, face and body applicators and a small leatherette-covered case.

THE DURANT ELECTRIC SUPPLIES COMPANY, 60 Fifth Avenue, Chicago, will send prices and samples of Ironite duplex drop wire upon application. Ironite is declared to be flexible and as easily handled as soft-drawn copper. It will not sag or stretch, and linemen can pull all the slack out of the line without fear of breaking the conductor.

THE HOLOPHANE COMPANY, New York city, in the November issue of *Holophane Illumination* gives considerable attention to the subject of good lighting in factories. A couple of interesting illustrations are shown of the use of the Holophane-D'Olier metal reflectors, throwing the light just where the workman needs it, and eliminating errors due to bad lighting.

THE GENERAL ELECTRIC COMPANY'S incandescent lamp works at Fort Wayne, Ind., will increase its output fifty per cent, which will mean 130,000 lamps a week. Superintendent H. K. Jones recently returned from a meeting of superintendents held at Harrison, N. J., with instructions to increase the output of the Fort Wayne plant. This will require some additional facilities as well as an increased force of men.

THE GRANT FLAMING LAMP COMPANY, 239 Railway Exchange Building, Chicago, district agent for the Grant flaming-arc lamp manufactured by the German-American Electric Company, New York city, has issued a descriptive folder and price list of lamps and carbons. The Grant lamp is manufactured in two standard types burning ten and seventeen hours, respectively, and its design is believed to present several advantages in operation and efficiency.

THE WESTERN ELECTRIC COMPANY, New York and Chicago, tells in booklet form what it is doing to increase the central-station load. In the past year of depression the company has prosecuted a sales campaign for electrical apparatus and supplies more vigorously than ever before and has met with a gratifying response. A large and important factor of this sales campaign has been advertising in the technical press, trade papers and popular magazines, advocating electric motor drive and electric illumination. The company's business has already been largely stimulated, and in consequence of the greater use of apparatus and supplies, the business of the central station has been correspondingly increased. The pages of the booklet are taken up with some illustrations of Western Electric advertisements that have appeared.

THE WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY, Pittsburg, Pa., is distributing the initial number of *Motor Talks*, a monthly house organ whose December issue is seasonably concerned "chiefly about Christmas." The company has prepared a suitable box, covered with holly paper and tied with red ribbon, to contain the electric motors for driving sewing machines and mechanical washing outfits, which it recommends as useful and appreciated gifts.

THE NERNST LAMP COMPANY, Pittsburg, Pa., announces that an order has been received for three-glower lamps to replace the six-glower Nernst lamps in the corridors of the Frick Building, Pittsburg. Nernst lamps have been used in this building for the last five years, and the new lamps will give the same amount of light as the old at a saving of twenty-five per cent in the current consumption. They have the added advantage of simplified renewal at a material reduction in cost.

THE CENTRAL ELECTRIC COMPANY, Chicago, is distributing a fifteen-page circular describing "O. K." fuse-block covers and meter-connection blocks. Thirty-six diagrams illustrate the methods of connecting and testing house meters without interruption to the service. The booklet is entitled "Theft of Current," and it is believed that the use of these connection blocks will effect a very considerable decrease in unaccounted-for current at central stations. A copy of this booklet will be sent upon request.

THE INTERNATIONAL ACHESON GRAPHITE COMPANY, Niagara Falls, N. Y., responding to a very general demand for Acheson graphite, grade 1340, combined with grease, for lubricating purposes, is now supplying several combination lubricants of unusual merit. The purity and smoothness of this product have won for it the highest appreciation as a lubricant. All who have used it are believed to realize that it is free from the impurities of natural graphites, finding this electric furnace product of great benefit in general lubrication.

JAMES BIGGS & COMPANY, 109 Liberty Street, New York city, announce that the Blackburn-Smith feed-water filter and grease extractor has been chosen for the new colliers—Mars, Hector and Vulcan—now being built for the United States Navy by the Maryland Steel Company. The filters are to be placed in the feed lines, securing the double filtration characteristic of the Blackburn-Smith apparatus. These filters are also used for protecting the boilers of stationary plants from floating particles of oil, grease, mud, etc., in the feed water. The manufacturers are distributing an interesting booklet on the subject of feed-water filtration.

THE DIEHL MANUFACTURING COMPANY, Elizabethport, N. J., devotes bulletin No. 56 to direct-current motors for driving sewing machines. The motor is so arranged that pressure on the treadle operates a lever which closes the switch and starts the motor. Further pressure engages the friction wheels of the transmitter and the degree of pressure regulates the friction between the wheels so that by varying the pressure on the treadle any desired speed may be obtained from a single stitch to the full speed of the machine. When the treadle is released a spring attached to the lever disengages the friction wheels, opens the switch and applies the brake.

THE GENERAL INCANDESCENT LAMP COMPANY, Cleveland, Ohio, has moved its general office from the factory at 1811 East Forty-fifth Street to Suite 202-208 Electric Building, Cleveland. Larger quarters were necessary, the company announces, in order to handle the greatly increased volume of business which it has secured since the introduction of the G. I. tungsten lamp. The General Incandescent Lamp Company is one of the oldest of its kind in the United States. It manufactures a full line of carbon, Gem and high-efficiency lamps, including miniature and low-voltage, both tantalum and tungsten lamps, for all voltages and conditions. It also has a special department where any special type of lamp can be promptly manufactured, and solicits this class of business.

THE PETTINGELL-ANDREWS COMPANY, Boston, Mass., dealers in electrical merchandise, is anticipating the holiday season in mailing copies of a handsome little descriptive booklet on Empire miniature lamps. These specialties are particularly useful for decorative purposes at Christmas time or for hotels, public buildings or house decoration at any season of the year. The lamps catalogued include almost every conceivable shape and style of globe and are made in a variety of colors and frostings. Some popular shapes include those designated as twist-flame, festoon, torpedo, candle, limousine and dome, besides a number of special lamps for surgical, instrument and other uses.

THE BOSTON INCANDESCENT LAMP COMPANY, Danvers, Mass., announces that in its page advertisement which appeared in the issue of the ELECTRICAL REVIEW AND WESTERN ELECTRICIAN for November 21, an error was made in stating that the lamps mentioned were made in candlepowers from four to fifteen. The company is anxious to have this error corrected, because the majority of the lamps sold are of sixteen candlepower, and at the reduced price at which the lamps are marketed the assumption might be made that only four to fifteen candlepower lamps were advertised, not including sixteen-candlepower lamps. The copy furnished by the Boston Incandescent Lamp Company read "four to sixteen candlepower," and the advertisement as it appeared was incorrect because of a typographical error.

THE CROCKER-WHEELER COMPANY, Ampere, N. J., is equipping the large textile mill of the Windham Manufacturing Company with electric drive. A complete electric power plant, including motors, transformers and switchboards, has just been shipped to the mills at Willimantic, Conn. The equipment consists of nine 550-volt squirrel-cage induction motors aggregating about 500 horsepower, which will be used to drive the machinery in the mill. The generating equipment consists of two 500-kilovolt-ampere generators. Sixty-cycle, three-phase current will be generated at 600 volts and transformed to 110 volts for lighting. The motors are all arranged for ceiling suspension. The transformers for the lighting system and the switchboard were also furnished by the Crocker-Wheeler Company.

THE BUREAU OF ILLUMINATING ENGINEERING, 437 Fifth Avenue, New York city, announces that it is prepared to carry out the work usually alloted to the illuminating engineering of commercial departments of central stations where the amount or character of the work will not permit the company's own engineers to undertake it, and the Bureau will also act as consulting engineer for companies maintaining these departments where advanced information is desirable. Unique contracts are being made in these connections, permitting a central-station company to submit a stipulated number of lighting problems over a stated period of time. In addition to engineering duties, the Bureau designs globes and reflectors, lighting fixtures, and outline, display and decorative lighting effects. Photometric and illuminometer tests are also made, and the Bureau oversees acceptance and performance tests on all characters of artificial illuminants and accessories. Major E. L. Zalinski, U. S. A. (retired), is president of the Bureau, and Albert J. Marshall, chief engineer.

PUBLICATIONS.

THE ELECTRICAL INDUSTRY OF PERU—Vol. II of the descriptive treatise on the electrical industry of Peru, by Emile Guarini, has been published. This covers the possibilities of electrical development in that country and the electrical service established at Lima and its environs. The price of the publication, which is in Spanish, is three sols, and it may be had from the Electrical Section de la Escuela Nacional de Artes y Oficios, Lima, Peru.

UNITED STATES PATENT OFFICE GAZETTE—Commencing with Volume 138, January, 1909, the Official Gazette of the United States Patent Office will be published in monthly instead of bi-monthly volumes. The yearly subscription price, $5, will remain unchanged, but the price of single volumes, unbound, will be fifty cents. Indexes, digests, and title pages for each volume will be furnished regular subscribers and purchasers of unbound volumes. The price of bound volumes will be $2.50.

WIRE INSPECTION BUREAU HANDBOOK—The Wire Inspection Bureau Handbook for November, 1908, issued by the Wire Inspection Bureau, 29 West Thirty-ninth Street, New York city, describes manufacturers' tests for rubber-covered wire and flexible cord. A list of the companies employing the Wire Inspection Bureau to make, supervise and verify tests on wire and flexible cord is given, with a sample of the Bureau's stamp, the presence of which indicates that the wire has successfully withstood the test prescribed.

NEW MANUFACTURING COMPANIES.

MINNEAPOLIS, MINN.—The Minneapolis Electric Motor Company has been incorporated with a capital stock of $50,000, to manufacture and deal in electrical supplies, machinery and fixtures. Walter H. Vilett, John W. Helm and John M. Zeessman are the incorporators.

ALBANY, N. Y.—A certificate of incorporation of the Bell Arc Light Company of Brooklyn has been filed with the secretary of state. The capital is $100,000, and the directors are Charles A. Campbell and Henry W. Van Alen of Brooklyn, and Monroe May of New York city.

NEW YORK, N. Y.—The Tesla Electrotherapeutic Company, of New York, has been incorporated to manufacture and deal in electro-hygienic and electrotherapeutic apparatus. Its capital is $400,000 and the incorporators are: Archibald M. Langford, Morton G. Bogue and Ward W. Pickard, all of New York.

DATES AHEAD.

American Roentgen Ray Society. Annual meeting, New York city, December 28-30.

Chicago Electrical Show. Coliseum, Chicago, Ill., January 16-30, 1909.

American Association for the Advancement of Science. Annual meeting, Baltimore, Md., January, 1909.

Northwestern Electrical Association. Annual meeting, Milwaukee, Wis., January, 1909.

RECORD OF ELECTRICAL PATENTS.

Issued (United States Patent Office) November 24, 1908.

904,522. CABLE CONNECTOR. John D. Firmin, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Filed August 20, 1906. A coupler has two threaded counterpart terminal members with threaded interfitting projections and clamping sleeve screwed over the extensions.

904,524. ELECERIC-LIGHTING DEVICE. Joshua T. Fisk, Rochester, N. Y., assignor to Metal Specialties Manufacturing Company, Chicago, Ill. Filed October 28, 1907. An electrical cigar lighter is provided with a receptacle and a convolute resistance wire mounted in the same.

904,525 and 904,526. OVERHEAD ELECTRIC RAILWAY. Francis M. Frederick, St. Louis, Mo., assignor to Francis T. Moormann, Charles H. Poth, Thomas B. Poth and Frank J. Vollmer, St. Louis, Mo. Filed November 4, 1907. Comprises an elevated track rail, a motor-driven truck operating thereon, a car suspended from the truck and compressed-air means carried by the car for raising or lowering it.

904,529. ELECTRIC FURNACE MUFFLE. John F. Hammond, Prince Bay, N. Y., and Ralph B. Savin, Philadelphia, Pa., assignors to the S. S. White Dental Manufacturing Company, Philadelphia, Pa. Filed February 27, 1908. Consists of a hollow electrically wired inner member, a hollow outer member and a plug fitting in the rear end of the latter.

904,532. ARC-LAMP ELECTRODE. Henry S. Hatfield and Frank M. Lewis, Brighton, England. Filed July 31, 1908. Composed of some eight parts of calcium fluoride, five parts of carborundum, and carbon.

904,540. PROCESS OF ELECTRIC WELDING. Laurence S. Lachman, New York, N. Y., assignor to Standard Pulley Manufacturing Company. Filed March 24, 1905. A process for uniting metal sheets by a number of autogenous spot welds at projections integral with the sheets.

904,541. DEVICE TO PREVENT TROLLEY WHEELS FROM JUMPING. William O. Lane, Cleveland, Ohio. Filed March 12, 1908. A pair of spaced guide arms is arranged to be connected to the pole and held in advance thereof.

904,550. AUTOMATIC FIRE-ALARM, BURGLAR-ALARM AND TELEPHONE SYSTEM. George F. Milliken, Boston, and Frederick W. Cole, Newton, Mass., assignors to Gamewell Fire-Alarm Telegraph Company, New York, N. Y. Filed October 16, 1905. A normally closed circuit connects the central station with subscribers' stations provided with telephone equipment and alarm-transmitting devices.

904,583. TELEPHONE SYSTEM. Harry G. Webster, Chicago, Ill., assignor to Kellogg Switchboard and Supply Company, Chicago, Ill. Filed February 28, 1903. Relates to a supervisory relay associated with the cord circuit.

904,592. ELECTRICAL CONDUCTOR SUPPORT. John S. Allen, Los Angeles, Cal. Filed March 22, 1906. A double petticoat insulator is suspended from a cross-arm and carries the conductor beneath it.

904,603. CONNECTOR. Clarence T. Crocker, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Filed August 31, 1906. A coupler for cables comprises terminal members having interfitting extensions and a pair of sleeves for clamping them together.

904,609. ELECTRIC INCANDESCENT LAMP. Frederic W. Erickson, New York, N. Y. Filed January 28, 1908. A light diffuser consists of a lamp having a plain globe, a casing about the same made of two interlocking parts, one a reflector and the other of colored glass.

904,616. STARTING MECHANISM FOR INTERNAL-COMBUSTION ENGINES. Henry C. L. Holden, Blackheath, and George K. B. Elphinstone, Lewisham, England. Filed October 28, 1907. Means for insuring that the mechanism used for giving a few turns to the crankshaft can only be brought into action when the sparking circuit is broken.

904,624 and 904,625. DEVICE FOR REVERSING THE DIRECTION OF ROTATION OF INTERNAL-COMBUSTION ENGINES. Leon Le Pontois, New Rochelle, N. Y. Filed August 2, 1907. An electrical ignition governor has an ignition circuit, one of whose electrodes is operated by an air-pump piston.

904,632. VIBRATORY APPARATUS FOR EAR TREATMENT. Eugene Meyer, New York, N. Y. Filed February 2, 1908. A vibratory hammer lever is provided with an armature actuated by an electromagnet.

904,640. ARC LAMP FOR STEREOPTICONS, ETC. Herbert F. Patton, Cleveland, Ohio. Filed May 13, 1907. Comprises means adapted to support two carbons at right angles.

904,645. BATTERY GRID. Franklin W. Post and Archie M. Morley, Los Angeles, Cal. Filed August 21, 1906. A storage-battery grid has opposite sets of spaced ribs disposed in parallel planes.

904,661. CIRCUIT-CLOSING RELAY. Jean F. Webb, Jr., Denver, Colo., assignor to the Electric Signagraph and Semaphore Company, New York, N. Y. Filed May 12, 1908. Two supporting frames for the magnets and armature respectively are arranged to be connected to a local circuit.

904,663. MANUFACTURE OF RAIL BONDS. Walter H. Williams, Mansfield, Ohio. Filed November 14, 1906. A stranded terminal member is made by separating the strands to form an aperture, then inserting one end into this and compressing the whole into a solid mass.

904,677. ELECTRIC-CURRENT BATHING TUB. Friedrich Braun, Dresden, Germany. Filed December 4, 1907. This tub has electrodes at its ends and an insulating partition across the tub and adapted to support the knees of the bather with the feet in one compartment and the body in another.

904,684. METHOD OF ELIMINATING COPPER FROM COAGULATED CELLULOSE. Emile Crumière, Paris, France. Filed February 19, 1908. Consists in passing a current through a solvent in which the cellulose is immersed so as to dissolve the copper and deposit it on a cathode.

904,693. SYNCHRONOUS SPEED INDICATOR. Arthur E. Griffin, Winthrop, Mass., assignor to Sears B. Condit, Jr., Boston, Mass. Filed March 13, 1905. An induction motor has a make-and-break device mounted thereon and operated by its rotor, and an indicator energized by alternating current and by induced current from the make-and-break device.

904,728. ELECTRIC-LAMP RECEPTACLE FOR ELECTRIC SIGNS. Frederick W. Ruby, Jackson, Mich. Filed March 20, 1908. The front edge of the socket is supported flush with the sign surface by two sleeves threaded over the socket.

904,741. ELECTRICALLY OPERATED SEMAPHORE MECHANISM. Jean F. Webb, Jr., Denver, Colo., assignor to the Electric Signagraph and Semaphore Company, New York, N. Y. Filed May 12, 1908. A motor drives a gear carried by the semaphore shaft.

904,743. ELECTRICAL PRINTING APPARATUS. Milton T. Weston, Orange, N. J. Filed September 25, 1901. Contains a number of electromagnetically controlled trip devices.

904,765. SYSTEM OF CONTROL FOR ELECTRIC MOTORS. Arthur C. Eastwood, Cleveland, Ohio. Filed May 9, 1908. There is a manually controlled resistance in series with the main motor circuit and a second resistance automatically cut out when the current in the motor is below a certain value.

904,768. TELEGRAPH SYSTEM. Stephen D. Field, Stockbridge, Mass. Filed December 1, 1906. An electromotive force counter to that of the line current is impressed on the line at the instant when the circuit is open to form the signals.

904,771. ELECTRIC WELDING MACHINE. Weston M. Fulton, Knoxville, Tenn., assignor to the Fulton Company, Knoxville, Tenn. Filed February 7, 1906. Consists of a number of yieldingly pressed rotatable electrodes for welding lapped seams.

904,776. SYSTEM OF ELECTRIC DISTRIBUTION. Caryl D. Haskins, Schenectady, N. Y., assignor to General Electric Company. Filed September 26, 1904. The rotor of a motor meter controls an electromagnet for periodically opening and closing the line switch.

904,780. SYSTEM OF CONTROL. George H. Hill, Schenectady, N. Y., assignor to General Electric Company. Filed March 23, 1907. Comprises a controller for alternating-current operation, a controller for direct-current operation and a master controller for governing both the controllers.

904,782. ROTARY CONVERTER FOR ELECTRIC WELDING. Arthur M. Hoffman, Johnstown, Pa. Filed December 23, 1907. A device for converting direct into alternating current consists of a commutating and resistance-controlling rotor.

904,783. INDICATING AND RECORDING INSTRUMENT. William F. Howe, Schenectady, N. Y., assignor to General Electric Company. Filed September 17, 1907. A motor meter has current and potential coils, a disk armature for the coils, a damping magnet and a pivoted sheet-metal indicating armature mounted in the field of the coils and of the magnet.

904,786. CIRCUIT CLOSER FOR FIRE-ALARM CIRCUITS. William W. Katterjohn, Henderson, Ky. Filed May 20, 1908. A spring connected to the circuit closer and adapted to close the same upon retraction is held in extended position by two series of oppositely placed eyes and cords.

904,788 and 904,789. AUTOMATIC CARRIER SYSTEM. Sam H. Libby, East Orange, N. J., assignor to Sprague Electric Company. Filed March 12, 1906. An electrically operated traveling carrier system is automatically controlled from the loading stations to the unloading stations.

904,794. GENERATION, CONTROL AND TRANSMISSION OF ELECTRIC ENERGY, PARTICULARLY FOR USE ON AUTOMOBILES AND LIKE VEHICLES. Albert H. Midgley, London, England. Filed February 26, 1908. The engine drives a dynamo having two armatures, one of which supplies current to the propelling motor.

904,801. CURRENT-COLLECTING APPARATUS FOR DYNAMO-ELECTRIC MACHINES. Jakob E. Noeggerath, Schenectady, N. Y., assignor to General Electric Company. Filed October 10, 1906. A laminated brush is pressed against the collector by a U-shaped spring on the brush holder.

904,808. INSULATING MATERIAL. George H. Rupley, Schenectady, N. Y., assignor to General Electric Company. Filed August 7, 1907. Is made from a fabric impregnated with a soft, pliable, non-adhesive material and coated with linseed-oil varnish.

904,810. DISTANCE CONTROL APPARATUS FOR TRANSLATING DEVICES. Ernest Schattner, London, England, assignor to General Electric Company. Filed August 6, 1906. A multiple-rate meter connected to a supply circuit has means responsive to currents of different frequency and arranged to set the meter to register at corresponding rates.

904,821. SHADE HOLDER FOR INCANDESCENT ELECTRIC LAMPS. John Weber, Schenectady, N. Y., assignor to August Weber, Sr., Schenectady, N. Y. Filed July 21, 1905. Is provided with telescopically engaging members adapted to interlock automatically with a snap action.

904,826. LAMP REDUCER. Charles Wirt, Philadelphia, Pa., assignor to Charles Wirt and Company, Newark, N. J. Filed March 18, 1907. A turn-down lamp socket has a rotary rheostat ring surrounding it.

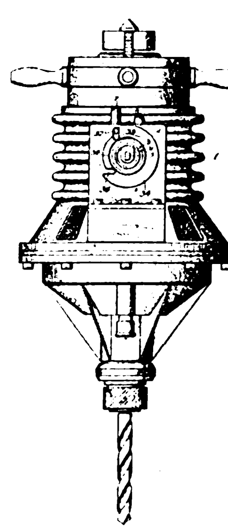
904,831. PROCESS OF MAKING HOMOGENEOUS BODIES FROM TANTALUM METAL OR OTHER REFRACTORY METALS. Werner von Bolton, Charlottenburg, Germany, assignor to Siemens & Halske Aktiengesellschaft, Berlin, Germany. Filed January 5, 1904. Consists in uniting the powdered metal into a coherent mass, then heating this to the melting point by means of an electric current.

904,832. ELECTRICAL FUSE PLUG. Harold E. Bradley, Greenwood, R. I., assignor to Marion C. Happoldt, Providence, R. I. Filed January 3, 1908. A cap engages and can be locked to the casing that receives the fuse.

904,834. ELECTRIC RAILWAY SIGNALING SYSTEM. Yorke Burgess, Washington, D. C. Filed December 7, 1907. Line conductors are formed in sections, each having portions in different planes.

904,850. TELEPHONE SYSTEM. Francis W. Dunbar, Chicago, Ill., assignor to Kellogg Switchboard and Supply Company, Chicago, Ill. Filed May 9, 1904. Describes a polarized line-signaling device connected to the line at the central office.

904,851. CONTROLLER FOR ELECTRIC DRILLS. William O. Duntley, Chicago, Ill., and Henry J. Kimman, Cleveland, Ohio, assignors to Chicago Pneumatic Tool Company, Chicago, Ill. Filed January 22, 1906. The drill is provided with grasping handles, a main switch arranged adjacent one of them, a reversing switch and a sleeve concentric with the handle for operating the latter switch.



904,851.—CONTROLLER FOR ELECTRIC DRILL.

904,871. ELECTROMAGNET. George W. Henry, New York, N. Y., assignor to Henderson P. Childress and John L. Lequin, New York, N. Y. Filed July 31, 1907. A magnet has an armature and a lever with a rocking fulcrum bearing and pivotal connection with the armature.

904,877. TROLLEY FOR CARS. John Kaufman, Hazleton, Pa., assignor to H. H. Shellenberger, Easton, Pa. Filed June 5, 1908. Mounted on a trolley pole is a two-part head hinged together on a vertical axis and a contact wheel journaled on the outer end of each part.

904,881 and 904,882. PROCESS OF ELECTRIC WELDING. Laurence S. Lachman, New York, N. Y. Filed May 8, 1907. Renewed April 23 and 27, 1908. The process of uniting two bodies of metals by a spot weld consists in providing at least one of the bodies with a perforation, placing them together and passing a current through them in the region surrounding the perforation.

904,887. VOLTAGE REGULATOR FOR DYNAMO-ELECTRIC MACHINES. George S. Neeley, St. Louis, Mo. Filed November 30, 1906. An alternator has an exciter and means for regulating the field resistance of the latter.

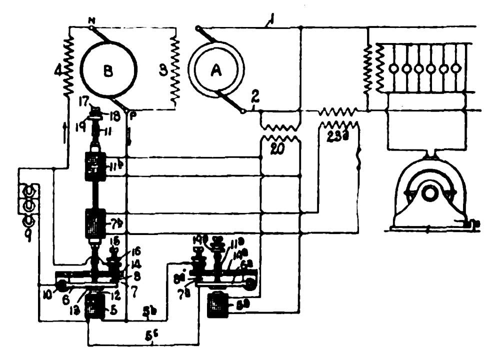
904,889. ALARM DEVICE FOR FIRE-ALARM BOXES. Joshua B. Nicholson and Artemus R. Warfield, Washington, D. C. Filed June 30, 1908. An electric bell adjacent the box is rung when the alarm circuit is closed.

904,890. BRAKE MECHANISM. Frederick H. Osborn, Garrison, N. Y. Filed February 4, 1908. An electrically controlled brake for a phonograph.

904,892. STREAM-POWER ELECTRIC FLOAT. William J. Pattosien, San Rafael, Cal. Filed December 17, 1907. A dynamo, having both field magnets and armature rotatable, is operated by two undershot waterwheels, one for the field magnets and the other for the armature.

904,894. DAMPER REGULATOR. William Roberts and Dellford H. Holloway, Waterford, N. Y., assignors to Charles W. Scoville, Cohoes, N. Y. Filed September 11, 1907. An electrically controlled damper-operating device.

904,897. ROTARY SWITCH. Frank J. Russell, New York, N. Y. Filed May 13, 1907. An electric switch is provided with a base having stationary contacts and rotatable switch plug stamped into rectangular form.

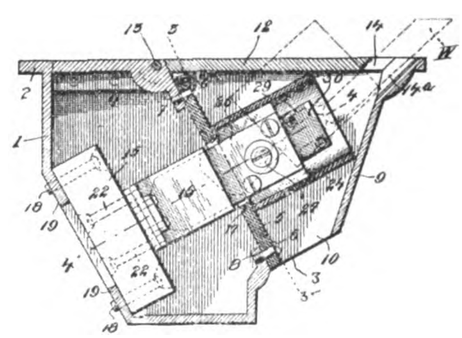


904,887.—VOLTAGE REGULATOR.

904,898. FLOOR-POCKET RECEPTACLE AND PLUG. Frank J. Russell, New York, N. Y. Filed June 7, 1907. A floor box has an inclined shield board which divides the box into separate compartments, a receptacle member in one compartment and a plug member arranged for insertion through the other compartment.

904,902. LINE INTERRUPTER FOR ELECTRIC RAILWAYS. Albert Thode, Hamburg, Germany. Filed July 8, 1908. An insulator has plates attached laterally to it that are adapted to raise a sliding bow from the latter when it passes under the line interrupter.

904,903. TELEPHONE ANNUNCIATOR AND JACK. Henry Tideman, Menominee, Mich. Filed July 6, 1907. A switchboard drop and jack.



904,898.—FLOOR RECEPTACLE.

904,906. DRUM CONTROLLER. Henry J. Wiegand, Milwaukee, Wis., assignor to the Cutler-Hammer Manufacturing Company, Milwaukee, Wis. Filed March 14, 1907. Combined with a number of reversing switches and resistance switches is a single drum provided with cams for actuating the switches.

904,917. CONDITION-CONTROLLING DEVICE. James I. Ayer, Cambridge, Mass., assignor to Simplex Electric Heating Company, Boston, Mass. Filed October 29, 1906. A pair of contacts is pivotally mounted in a support and a circuit-closing element is movable so as to engage either contact.

904,918. SIGNALING SYSTEM. Garrison Babcock, Rochester, N. Y., assignor to Merton E. Lewis, Rochester, N. Y. Filed May 31, 1906. An alarm system is equipped with substations consisting of a box, a break-wheel mechanism and telephone apparatus within the box.

904,925. SYSTEM OF ELECTRICAL DISTRIBUTION. William L. Bliss, New York, N. Y. Filed August 4, 1904. An axle car-lighting system.

904,928. ATTACHMENT FOR SAFETY FUSES. William J. Boemper, Rutherford, N. J., assignor of one-half to Harry A. Muecke, New York, N. Y. Filed October 4, 1907. A safety-fuse clip is provided with two pivotally connected curved arms.

904,936. TELEGRAPH REPEATER. Lewis B. Cecil, Santa Barbara, Cal. Filed February 25, 1908. Consists of a main-line and a branch-line relay.

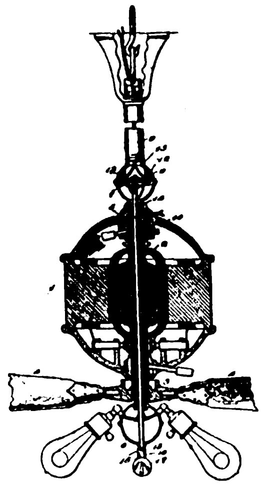
904,945. WIRE BRACKET OR HOLDER AND INSULATOR. Isaac L. Edwards, Aurora, Ill. Filed March 5, 1908. A box made of separable sections united by a joint has an insulator within it formed of separable sections.

904,952. COMBINATION TROLLEY AND TELEGRAPH POLE. James Hackett, Bellaire, Ohio. Filed August 14, 1908. The pole comprises stepped sections, a head carried by the upper one and having extensions for insulators and cable supports.

904,969. LIGHTNING ROD. George R. Kress, Pittsburg, Pa. Filed February 6, 1908. There is in combination a top section, a continuous line rod and a separate Y-shaped joint, connected to the section and rod.

904,971. AUTOMATIC RAILWAY ALARM. Niels Lang, Vancouver, British Columbia, Canada. Filed April 21, 1908. An electric circuit extends throughout the section of track to be protected, one end being connected to the rails and the other to a series of contact plates at intervals along the track.

904,979. HOLDING DEVICE FOR NEWSPAPERS. John K. Morris, Newhall, Cal. Filed May 8, 1908. A pair of jaws works with a rod having a wedge-shaped head on the opposite end and electrical means for ringing a bell when the rod is forced backward by a paper.



905,089.—CEILING FAN.

904,985. EMERGENCY VALVE. Oliver Penn, Pittsburg, Pa. Filed July 1, 1908. A pair of electromagnetic devices operates the valve.

904,991. PROCESS OF SMELTING METALLIC COMPOUNDS AND PRODUCING CARBIDES. Edgar F. Price, Niagara Falls, N. Y., assignor to Union Carbide Company, Niagara Falls, N. Y. Filed July 14, 1904. A process of making calcium carbide consists in preheating a calcium compound and carbon and then electrically heating the mixture.

904,999. BRAKE-SETTING MECHANISM. William A. Rideout, Sr., Oshkosh, Wis. Filed February 24, 1908. An electric circuit includes a magnet to release the valve lever.

905,014. FLEXIBLE SUSPENSION FOR CONDUCTORS. Louis Steinberger, New York, N. Y. Filed September 23, 1907. A cross-arm carries a collar and an insulating sleeve supporting a number of suspension-type insulators.

905,045. ELECTRIC HEATING DEVICE. James I. Ayer, Cambridge, and Horace B. Gale, Natick, Mass., assignors to Simplex Electric Heating Company, Cambridge, Mass. Filed June 13, 1908. The heating element consists of a heat-absorbing body provided with a series of grooves and a ribbon-like current conductor secured in them.

905,048. APPARATUS FOR THE EXTRACTION OF GOLD FROM CRUSHED ORES. Thomas E. Beaumont, London, England. Filed March 29, 1906. An amalgamator forming part of an electric circuit is placed in the base of a vessel in whose upper part is a series of annular electrode plates.

905,066. OUTLET BOX FOR ELECTRIC WIRES. John Fountain, Jr., Elizabeth, N. J., assignor to Sears B. Condit, Jr., Boston, Mass. Filed August 3, 1908. An outlet box has a transverse apertured connector mounted in its wall so as to turn freely in all directions.

905,089. CEILING FAN. Fred P. McBerty, Warren, Ohio, assignor to the Peerless Electric Company, Warren, Ohio. Filed November 20, 1907. Relates to the mounting of an electric motor-driven fan.

905,114. ELECTRIC TRACTION ELEVATOR. De Witt C. Suplee, Philadelphia, Pa., assignor to Suplee Elevator Company. Filed January 3, 1908. The arrangement of a motor-driven cable gear is described.

905,115. ELECTRICAL INTERRUPTER. Henry M. Sutton, Walter L. Steele and Edwin G. Steele, Dallas, Tex. Original application filed September 24, 1904. Divided and this application filed December 2, 1907. Comprises a number of rotatable slotted disks, terminals at the opposite sides thereof and means intermediate each terminal and disk for varying the charging period of the disk.

905,119. INCANDESCENT ILLUMINANT. Orlando M. Thowless, Newark, N. J., assignor to Herbert L. Thowless, Newark, N. J. Original application filed March 8, 1899. Divided and this application filed July 25, 1899. A glower for electric lamps, which is a non-conductor at normal temperatures, but which becomes conductive and incandescent under the action of the current when heated, consists of a mixture of zirconium, thorium and aluminum oxides.

905,126. PRINTING-TELEGRAPH RECEIVER. John Burry, Ridgefield Park, N. J.; Marie Burry executrix of said John Burry, deceased. Filed March 30, 1906. In combination with a lever and a type plate carried thereby, are a number of fulcrums for the lever and electrical means for oscillating the lever on any of the fulcrums.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired December 1, 1908:

464,001. TELEGRAPH REPEATER. R. L. Atkinson, Delaware Township, N. J.

464,005. TREATING FILAMENTS FOR INCANDESCENT ELECTRIC LAMPS. J. Bradley, Massillon, Ohio.

464,025. POTENTIAL INDICATOR. C. E. Kammeyer, Eau Claire, Wis.

464,027. FIELD MAGNET FOR DYNAMOS OR MOTORS. C. E. Kammeyer, Eau Claire, Wis.

464,055. ELECTRIC HEATER. P. Wright, Denver, Colo.

464,063. ELECTRIC MOTOR. M. H. Collon, Denver, Colo.

464,090. ELECTRIC APPARATUS FOR USE ON RAILWAY TRAINS. R. A. Wilder, Cressona, Pa.

464,125. METHOD OF TESTING INSULATED WIRES. R. Varley, Jr., Englewood, N. J.

464,132. ELECTRIC ARC LAMP. Wm. A. Nicholson, New York, N. Y.

464,133. RELAY. R. Varley, Jr., Englewood, N. J.

464,134. ELECTRIC CIRCUIT CLOSER. R. Varley, Jr., Englewood, N. J.

464,136. ELECTRIC REGULATOR. C. W. Holtzer and G. E. Cabot, Brookline, Mass.

464,152. ELECTRIC TRANSMITTING TELEPHONE. R. Eickemeyer, Yonkers, N. Y.

464,156. ELECTRICAL GENERATOR. V. Hirbec, Paris, France.

464,198. ELECTROMAGNET. O. E. Lundstedt, Brooklyn, N. Y.

464,216. ARMATURE FOR DYNAMOS AND ELECTRIC MOTORS. St. John V. Day, St. Louis, Mo.

464,231. ELECTRIC MOTOR. J. R. Robinson, Salem, Mass.

464,244. ELECTRIC FIRE ENGINE. M. W. Dewey, Syracuse, N. Y.

464,245. ELECTRIC HOSE CARRIAGE. M. W. Dewey, Syracuse, N. Y.

464,246. ELECTRICALLY PROPELLED VEHICLE. M. W. Dewey, Syracuse, N. Y.

464,247. ELECTRIC HEATING APPARATUS. M. W. Dewey, Syracuse, N. Y.

464,248. ELECTRICALLY PROPELLED VEHICLE. M. W. Dewey, Syracuse, N. Y.

464,299. ELECTRIC MOTOR. H. A. Florian, Detroit, Mich.

464,347. MAGNETO-ELECTRIC IGNITER FOR COMBUSTIBLE-VAPOR ENGINES. L. G. Woolley, Grand Rapids, Mich.

464,470. ELECTRIC ELEVATOR. W. Baxter, Jr., Baltimore, Md.

464,475. JOINT FOR ELECTRIC CONDUCTORS. H. W. Fisher, Pittsburg, Pa.

ELECTRICAL REVIEW
AND
WESTERN ELECTRICIAN

VOL. LIII, No. 24. CHICAGO, SATURDAY, DECEMBER 12, 1908. ISSUED WEEKLY

BY THE
ELECTRICAL REVIEW PUBLISHING COMPANY.
CHARLES W. PRICE, President.
STEPHEN H. GODDARD, Vice-President. H. S. TUTHILL, Secretary.
PHILIP S. DODD, Manager. C. W. FORBRICH, Assistant Treasurer.

PUBLICATION OFFICE: 204 DEARBORN STREET, CHICAGO.

The present publication comprises: ELECTRICAL REVIEW, VOL. LIII, No. 24; WESTERN ELECTRICIAN, VOL. XLIII, No. 24.

EASTERN DEPARTMENT . . . . 13 Park Row, New York.

Application made for entry at the Post Office at Chicago as second-class matter under the Act of March 3, 1879.

CONTENTS.

LOAD-FACTORS AND DIVERSITY-FACTORS.

Although several definitions have been put forward to explain the meaning of "load-factor" and "diversity-factor," the definitions introduced by Mr. Robert Hammond and also by Mr. Arthur Wright have been generally accepted.

Load-factor is the ratio of the average load, represented by actual sales to consumers, to the maximum load supplied to the feeders at the station, expressed as a percentage; that is to say, it is the number of units sold during the year times 100, divided by 365 times twenty-four times the maximum load.

It is thus evident that even if all the consumers had a steady twenty-four-hour load, the load-factor as thus defined could not be 100 per cent, for the average load represented by the number of units sold, divided by the proper denominator, includes the losses in distribution. This may be a considerable percentage, especially in the case of alternating-current transformer systems. Ambiguity sometimes occurs, because some engineers take the maximum load as the total maximum load on the bus-bars, including the power used on the works. Others take only the maximum load supplied to the feeders, which is conceded to be the more correct way. If the power used at the works is included, the load-factor will often come out at a much lower figure.

The diversity-factor is the ratio of the sum of the consumers' demands to the maximum demand on the feeders at the station bus-bars. It is thus always greater than unity, although there can be a hypothetical case in which the consumers' maximum demands might occur simultaneously, in which case the demand on the feeders would be greater, as it would include the distribution losses; so that, in this instance, the diversity-factor, in accordance with the accepted definition, would actually be somewhat below unity.

In calculating diversity-factor, the station auxiliaries and lighting may be regarded as a consumer if desired, in which case the ratio would be taken as the sum of the consumers' maximum demands and the maximum demand by the station auxiliaries and lighting to the maximum power delivered from the bus-bars, including the power used on the works.

This analysis of load-factors and diversity-factors formed the subject of Mr. W. W. Lackie's address as chairman before the Glasgow local section of the Institution of Electrical Engineers, of Great Britain, last month. Mr. Lackie is engineer-in-chief of the Glasgow Electricity Department. Aside from his very interesting analysis of the definitions and usages of these two terms, Mr. Lackie made a suggestion which provides a very generous portion of food for thought. In Glasgow, as in other large industrial centres, the power-station engineer finds the power load creeping up to, and often overtaking, the lighting load, as electricity becomes more generally used. The power load also is fairly steady, and the variation in total output follows almost directly the growth of the system. On the other hand, the lighting load varies considerably with the season, and also varies from day to day, according to the amount of sunlight which the vagaries of the weather make available. In Glasgow the lighting customers are charged at a flat rate for a maximum demand, and power customers are charged on a similar system, but at a lower rate. If a set of customers do not use their maximum demand, they do not pay all their standing charges, and are therefore a loss to the undertaking, notwithstanding the fact that throughout they have to pay a higher rate under a maximum-demand system. A consumer paying the maximum charge per unit may be an unprofitable consumer, while an industrial consumer paying a lower price per unit throughout for a long-hour power supply will make a solid contribution to the profits of the supply undertaking.

Mr. Lackie states that at present many companies and supply authorities in supplying energy for power purposes allow their consumers to use five or ten per cent, and in some cases twenty per cent, of their consumption for lighting, the whole being charged at power rates. If this is right, he considers we may look forward to a time when the total demand for lighting will be, say, only ten per cent of the total output, the other ninety per cent being used for power and heating purposes; and electrical energy used for lighting purposes will then be thrown in at a price corresponding to our charge for power today. The effect of the metallic-filament lamp helps on this idea by reducing the present demand and corresponding consumption of energy for lighting purposes; whereas we feel certain that no such vital change in the efficiency of motors can take place so as to reduce, in a similar manner, the demand made by our power consumers.

ELECTROBUS COSTS.

What appears to be a reasonably authentic summarization of operating costs and earnings of electrobuses has been made public by one of the companies operating a system of public electric carriers in London, England. When the London system was inaugurated about eighteen months ago, we raised a question as to whether profitable operation would be possible at the rate of fare charged, taking into consideration the heavy depreciation on all parts of the system and the high cost of current for electrical charging of the storage batteries.

From the reports of the auditors of the company operating the electrobuses, it appears that, contrary to general expectations, the service has become very popular, and that as the number of carriages has been increased, the revenue per carriage-mile has also increased. While for the first three months the earnings were considerably less than the cost of operation plus the overhead and establishment expenses, the revenue for the fifteen months ending last October was sufficient to pay operating costs, ulterior expenses, and leave a small profit.

TRANSPORTATION DEVELOPMENTS IN BOSTON.

The opening of the new Washington Street tunnel in Boston on Monday, November 30, marks a definite step forward in the working out of a comprehensive scheme of transportation for the larger community of which that city is the centre. Although the tunnel is but a little over a mile in length, it illustrates the latest ideas in the field of engineering design and construction, and in its relation to the existing elevated system of the city, it assumes a position of fundamental importance. In the past, the most densely populated shopping district of Boston has been well served by surface cars, and later by the nearness of the Tremont Street subway, but today the inauguration of travel in the new tunnel shortens the gap between the residential districts of the north and south and the retail centre and financial section to an extent only a citizen of the Hub can fully appreciate. The restoration of surface car traffic in the original subway will shortly be completed, and with the clear result that on its north and south axis Boston will be finely provided with facilities for real rapid transit.

The completion of the Forest Hills elevated extension and the pushing of the elevated lines into the Malden and Everett section will still further strengthen the situation, and with the East Boston tunnel, will furnish service of a high character radially into and out of Boston through an arc of about two hundred and seventy degrees. Already active plans are under way for the building of a subway to Harvard Square, Cambridge, with a rapid transit extension in the near future to East Cambridge, and a little farther in the future, the building of a subway under the South Embankment of the Charles River for the special service of the directly western suburban territory. Thus, there appears to be work enough ahead to keep both the Boston Elevated Railway Company and the Boston Transit Commission busy for some years to come. Although facilities are often outrun by traffic in these days of urban expansion, each new route opened affords a considerable measure of relief, and the people of Boston are to be congratulated on this latest addition to their underground lines, which avoids the features which experience has shown undesirable in the earlier subway construction and sets a standard toward which future workers may well look in their efforts to develop high speed underground travel according to the most advanced resources of engineering.

THE TRAINING OF WORKMEN.

It is not long since Mr. F. W. Taylor, in his classic paper before a meeting of the American Society of Mechanical Engineers, outlined a system of training and rewarding workmen which attracted the greatest attention from shop managers and educators in general. The optimism with which Mr. Taylor developed and presented his ideas had the hearty support of that master mind, Dr. Robert H. Thurston, but those in charge of large organizations of workmen were skeptical, and there have been few actual trials of the system outlined. It can be stated as a fact, however, that this system, in connection with the other work of Mr. Taylor, has so greately increased the output and reduced the cost of work in the large machine shop of the Bethlehem Steel Company that for the past seven years

Mr. H. L. Gantt has given a large portion of his time to the development of its possibilities. In an address before the recent New York meeting of the American Society of Mechanical Engineers, Mr. Gantt made the statement that the results have far exceeded his expectations.

Under the system outlined by Mr. Taylor, each man has his work assigned to him in the form of a task to be done by a prescribed method with definite appliances, and to be completed within a certain time. The task is based on a detailed investigation by a trained expert of the best methods of doing the work. The task-setter or his assistant acts as an instructor to teach the workman to do the work in the manner and in the time specified. If the work is done within the time allowed by the expert, and is up to the standard for quality, the workman receives extra compensation in addition to his day's pay. If it is not done in the time set, or is not up to the standard of quality, the workman receives his day's pay only.

Mr. Gantt holds that people, as a rule, prefer to work at the speed and in the manner to which they have been accustomed, but are usually willing to work at any reasonable speed and in any reasonable manner if sufficient inducement is offered for so doing, and if they are so trained as to be able to earn the reward. The task and bonus method of training not only furnishes the workman with the required knowledge, due to the assistance from trained and expert instructors, but, by offering an inducement to utilize the knowledge properly, the workman is trained in the proper habits of work.

Habits of work in a mechanic are comparable with habits of thought in an engineer. Our industrial schools should make proper habits of work the basis on which to build their training in manual dexterity. The engineering school does not make engineers, but tries to furnish its graduates with an equipment that will enable them to utilize readily and rapidly their own experience and that of others.

Under the task system, workmen are taught how, and trained to do, at the same time. Knowing and doing are thus closely associated. Many skilled workmen make their skill an excuse for slow work, and unless, when they are taught how to do, they are also taught to do efficiently, they never attain the success which should be theirs and thus continually fall short of the economic ideal which shop management might attain to.

So it is evident from Mr. Gantt's experience that there is an economical as well as a humanitarian advantage in striving to bring out and make the greatest use of the best characteristics of the workman. The ordinary workman becomes a gang foreman, then a general foreman and a shop superintendent, because for his ability he stands out above all others. If, in his progress upward, there have been developed in him the proper habits of thought and a passion for doing his work efficiently, the greatest possible gain has been made both for trade and for posterity. One of the most satisfactory evidences of the value of Mr. Gantt's work and his paper describing it was the enthusiastic commendation which was accorded him at the conclusion of his address by the foremost engineers of the day in attendance at the convention.

CANDLEPOWER—FLUX—ILLUMINATION.

The standard candle adopted by the gas referees in London in the year 1860 as the unit of light will continue, with slight modifications, to be the standard of intensity. As a rating for modern light source candlepower of itself has little value, owing to the fact that lamps are rated at the angle of maximum intensity and the angle varies through ninety degrees even in lamps which can be used for similar purposes. For example: The maximum intensity of the majority of incandescent lamps is in the horizontal direction, while the maximum for the downward type of incandescent and the Nernst glower are directly underneath. In the larger units the enclosed arc varies considerably below the horizontal, while the flaming type have characteristics similar to the downward filament and Nernst types. Instead of the maximum intensity the average intensity has been suggested as a rating.

The unit of flux is the mean spherical candlepower multiplied by four, or the "lumens generated." Some authorities have given mean spherical candlepower as the unit of flux, but in the calculation of illumination the "lumens generated" is held to be the more convenient term. The mean spherical candlepower can be readily determined from the polar diagram, and photometers are now available by means of which this value may be obtained with a single reading. There is a variable of considerable importance which is not taken account of with this rating and that lies in the fact that the losses by reflection will be smaller in the case of lamps giving the larger percentage of the total flux below the horizontal.

The unit of illumination is the foot-candle and not candle feet, as the value is sometimes erroneously stated. The efficiency is expressed in the "lumens effective" (watts per square foot per foot-candle). The last named will vary widely with various colors of ceilings and walls, but under the same conditions the ratio of efficiency as represented by the percentage of lumens which are effective as against lumens generated will be in favor of the unit giving the larger flux in the lower hemisphere.

AN ELECTRIC YACHT CHARGING TENDER.

One of the enterprising yachtsmen of the New York Yacht Club has had built for use as an auxiliary to his electric yacht an electric charging launch, which has been named the Kilowatt. This makes the electric launch independent of short charging stations, and, it is stated, gives the yacht a radius of action practically unlimited. The auxiliary carries 400 gallons of gasoline, enabling her to be operated at full power for 100 hours, during which time she can recharge the batteries aboard the electric yacht ten or twelve times, giving a sailing distance of somewhat over 2,000 miles.

The pleasures of a yacht depending upon electric motive power are well known, and attention need hardly be directed again to the advantages of the elimination of smoke and cinders, the lessened possibility of explosion and conflagration, and the doing away with malodorous fumes and gases. The gasoline tender, it is believed, solves the question of the use of electricity in large motor yachts.

Electric Yacht with Charging Tender.

A gasolene and electric charging launch has recently been built by the Electric Launch Company which is to be used in southern waters as an auxiliary to the electric yacht Cascapedia, owned by Benjamin Douglass, Jr. The launch is named Kilowatt and is thirty-five feet long, nine feet beam and two feet draft.

The boat's power equipment consists of a forty-horsepower, six-cylinder gasolene engine, with mechanical reverse-gear connected to the propeller shaft, the engine driving a thirty-horsepower dynamo which is directly connected to the forward end of the engine. It is so arranged that electricity can be generated when the boat is under way or while lying at anchor. A slate switchboard located on the port side of the cabin, with the necessary instruments and switches, distributes the power to the electric yacht for recharging the batteries. The plant has a capacity for recharging the yacht's batteries in three or four hours.

With the Kilowatt as an auxiliary the electric yacht Cascapedia is not dependent upon electricity ashore for recharging her batteries. On one charge the yacht has a capacity of 200 miles, but in connection with the auxiliary charging launch Kilowatt her radius of action is unlimited. The auxiliary launch carries 400 gallons of gasolene, enabling her to be operated at full power for 100 hours, in which time she could recharge the electric yacht ten or twelve times and enable the Cascapedia to cover 2,000 miles before the auxiliary launch would have to replenish her fuel. This is the first electric auxiliary boat ever built, and it does much to solve the question of the use of electricity in large motor boats. The advantages of electricity for cruising boats are well known: Absence of noise, heat and vibration, absolute safety while afloat, no danger of fire or explosion, and ease of control. One man can handle the largest electric yacht. The boat has been shipped to West Palm Beach, Fla., where the owner will use her during the winter.

Independent Wireless Communication Made Possible.

Bellini and Tosi, two Italian scientists, who, with the sanction of the French Government, have been conducting experiments in wireless telegraphy for eighteen months on the coast of Normandy, announce that they have solved the problem of independent wireless communication.

This result, they say, has been secured by means of two rectangular aerials fixed at right angles and so attached to the apparatus for reception and transmission as to permit the passage of unequal currents. By a simple law of mechanics these two electromagnetic forces unite and produce an electromagnetic field, and the Hertzian waves are projected in a single vertical plane, which can be alternated instantly by means of the Bobine device.

The inventors say that they have picked up messages at will from every English wireless station and from ships at sea, and that they have transmitted messages from Courville to Havre and other points without the waves being perceptible at the other stations lying just off the line of transmission.

They claim that their system insures absolutely independent communication and opens up immense advantages in the use of wireless telegraphy.

New York & Ontario Power Company.

Plans and details of the New York & Ontario Power Company, of Waddington, St. Lawrence County, which proposes to furnish waterpower in Northern New York, have been explained to the Public Service Commission, Second District, at a hearing on November 30, on the company's application for permission to issue $1,800,000 in bonds and $654,741 in stock. The commission reserved decision.

It was shown that the company has a possibility of developing 30,000 horsepower, but proposes at the present time to develop 17,200. The power is to come from a stream which flows into the St. Lawrence River, and as a consequence the company believes continuous power is assured without the necessity of a storage dam.

Receivers for Auto Transit Company.

The Auto Transit Company, Philadelphia, being unable to meet its obligations, has been placed in the hands of receivers. The application for the receivership was made by the Electric Storage Company, which supplied power to the electric omnibuses of the Transit Company and was its creditor to the extent of over $30,000. The city of Philadelphia is also a creditor for $2,500 for unpaid licenses and $4,000 for repairs to streets used by the company's vehicles. The service was begun in July, 1907, and although at first popular was not patronized extensively when the fare was raised from five to ten cents to make the receipts meet the expenditures. Should there be a disposition to pay the higher fare needed for the maintenance of the service it will be resumed and the company reorganized.

Westinghouse Company Solvent.

The receivers of the Westinghouse Electric and Manufacturing Company and the Securities Investment Company were discharged in the United States Circuit Court on December 5, by Judge James S. Young.

Petitions for the discharge of the receivers were presented to the court by George Gordon, representing the various consenting interests. The companies were represented as being in sound financial condition. The debts of the Westinghouse Electric and Manufacturing Company have been arranged for, with the exception of unassenting creditors with claims to the amount of about $700,000, who will at once be paid in cash. The company has cash on hand amounting to about $15,000,000. The cash of the Securities Investment Company now on hand is about $17,000,000, with unassenting creditors representing only about $15,000.

Mr. Gordon asked that no account be filed by the receivers, stating that they had reported the condition of the plant from time to time to the company, and that the making of account would interfere greatly with the company at this time. The judge agreed to this motion.

Alaska-Yukon-Pacific Exposition.

During the summer of 1909 the Alaska-Yukon-Pacific Exposition, produced at an estimated cost of $10,000,000, will be held at Seattle, Wash., a commercial seaport of growing importance on the Puget Sound. The exposition will draw upon the territory named in its official title for the major part of its rich exhibits.

The grounds, 250 acres in all, are a part of the campus of the University of Washington, and are beautifuly situated between fresh-water lakes in the midst of a forest of giant trees and in plain sight of several ranges of mountains, including snow-capped Mt. Rainier, at an altitude of 15,000 feet.

Fifteen large buildings, of handsome architectural design, will comprise the exhibition palaces. Besides, the United States Government has expended $600,000 for its own building and exhibits, and fifteen states will be represented by beautiful edifices. A number of foreign countries will participate. The amusement section of the exposition will be known as the Pay Streak, a suggestive term from miners' vernacular. Residents of Seattle give every assurance of perfect weather during the exposition, which will open June 1 and close October 16.

Lewis Institute Branch, American Institute of Electrical Engineers.

One of the most successful meetings ever held by Lewis Institute branch of the American Institute of Electrical Engineers, was that on the evening of December 2, at which an audience of over 400 assembled to hear an address on "Rehabilitation of Chicago Street Railways," by Ralph H. Rice, assistant engineer, Board of Supervising Engineers, Chicago Traction.

Mr. Rice called attention to the prevailing tendency for the public control of all public utilities, which was well illustrated in the new franchises of the Chicago traction companies, in which the Board of Supervising Engineers, thereby created, corresponds to a public-service commission. In tracing the history of the traction problem in Chicago for nearly ten years back, it was evident that the poor service formerly rendered was due to the uncertainty of franchise renewal caused by the agitation for municipal ownership, which resulted in making it impossible to get capital for improvements and rehabilitation of equipment. It was interesting that in a voluminous report on this problem made by Bion J. Arnold in November, 1902, there were recommended most of the features subsequently incorporated in the franchise ordinances of February, 1907. It took nearly five years to secure their adoption, but in the one-and-one-half years since over half the work has been carried into effect.

The main features of these ordinances were pointed out and shown to be far in advance of anything ever attempted in this line. The functions of the supervising engineers in seeing that the provisions are carried out were explained, and the organization and duties of the engineering corps described. The work done by the different branches of this corps was illustrated by considering in detail the typical methods made use of by the division on power distribution, with which the speaker is connected. Preparations of plans, securing of estimates, inspection of the work and progress reports thereon, checking of the companies' accounts and issuance of the final certificate showing proper expenditures to capital account were explained in proper sequence. The speaker then considered at length the engineering features relating to calculation of a feeder system and practical problems met in its installation.

A brief summary of the work done and the amounts expended was given. The Chicago City Railway Company has completed seventy-five miles of rehabilitated and new single track; the Chicago Railways Company sixty-six miles. The former company has laid 2,800,000 duct-feet of conduit and installed 587,000 feet of cable in fifteen months; the latter company has laid 1,260,000 duct-feet of conduit since April 1. An interesting feature in the new equipment is the use of pay-as-you-enter cars, which were successfully introduced for the first time in this country on the South Side lines a year ago and which are being rapidly put in service throughout the city. To the original valuation of the surface traction properties, placed at $50,000,000 at the time of passage of the ordinances, there has been added $21,000,000, which represents approved expenditures for rehabilitation and new equipment, making the total capital account at the present time $71,000,000.

At the conclusion of Mr. Rice's address he met the members of the branch at close range in an upper hall of the Institute and answered many questions in regard to all aspects of the rehabilitation work and particularly in regard to details of its technical features.

Creosote for Railway Ties.

The Pennsylvania Railroad has determined to treat with creosote ties for its main tracks that their life may be prolonged. Some two years ago the company undertook tree planting upon a large scale. Since that time it has set out some 2,425,000 trees and has handled this year some 625,000.

In order to provide still more completely against the future a contract has just been placed for the construction of a tie-treating plant at Mt. Union, Pa., and, in addition, two large creosote storage tanks to be located at Greenwich Point, Philadelphia, Pa. The Mt. Union plant will be the first creosoting operation undertaken on a large scale by an eastern railroad.

It is estimated that proper treatment will increase the life of cross-ties from two to three fold. Applied to all of the 100,000,000 ties which American railroads use annually, it would greatly reduce the drain on the rapidly-decreasing timber resources. The Pennsylvania Railroad alone uses from 3,500,000 to 4,000,000 ties each year. The average life of these red oak and chestnut ties under present conditions is from three to four years, while white oak lasts from seven to eight years.

Revision of Patent Office Rules.

It has been decided to publish a revised edition of the Rules of Practice of the United States Patent Office because of the changes which have been made in such rules since the publication of the last edition. In view of this fact and in order, if possible, to simplify and improve the rules governing the practice before this bureau the Commissioner of Patents desires to obtain suggestions as to amendment of the present rules and would be glad to hear from those interested upon the subject. It is not proposed to make radical amendments to the present rules, but simply to embody such changes in or additions to the rules as will be beneficial both to the office and to applicants. All suggestions should be submitted prior to January 1, 1909, and addressed to Edward B. Moore, Commissioner, United States Patent Office, Washington, D. C.

$2,000,000 Trolley Line to Connect Urban Roads.

A $2,000,000 trolley line will be built which is to connect the Chicago & Milwaukee (the Frost road) with the Ravenswood branch of the Northwestern Elevated at Kedzie Avenue, Chicago. The corporation has been organized by D. H. Louderback, and the funds secured. Chicago capital, exclusively, is enlisted. The tracks are to run from Central Avenue, North Evanston, tapping the Frost line there, to Rockwell Street, Ravenswood, where connection is to be made with the overhead company, a distance of about ten miles.

This territory is well populated. It embraces several suburbs, including McAllister, which is owned by Louderback and his associates. The new company will not come in competition with any urban transportation service.

Chicago & Milwaukee Electric Railroad —New Receivership.

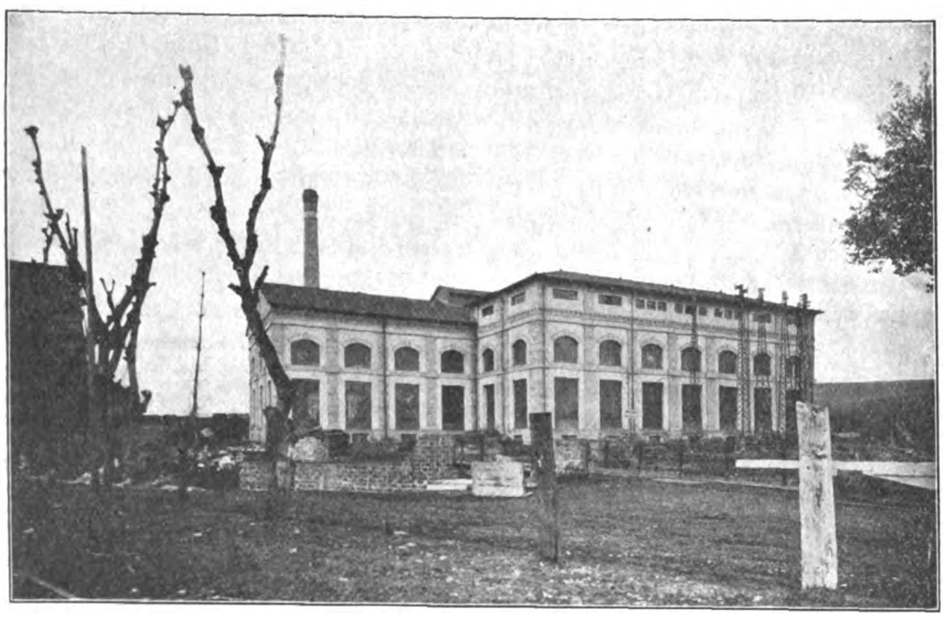
An order assuring the reorganization of the Chicago & Milwaukee Electric Railroad and marking one of the most important steps toward the settlement of the financial difficulties of the interurban line was issued on December 2 by Judge Grosscup. The former receivers were reappointed, but with enlarged duties. The immediate consequence of this action is expected to be the formulation of a plan of financial reorganization, the success of which is apparently assured beforehand by the harmonious action of the holders representing $8,500,000 out of a total of $10,000,000 of bonded indebtedness.

The Power Plant and Transmission System of Castelnuovo-Valdarno, Italy.

BY FRANK KOESTER.

The Societa Mineraria ed Elettrica del Valdarno possesses in the province of Tuscany, near San Giovanni-Valdarno, rich lignite fields. The mining of this coal was not a great commercial success, because it is of a low heating value and contains from forty to fifty per cent moisture. For these reasons it paid to ship only large lumps any distance, and it was not economical to install drying apparatus for that which remained unshipped.

Taking it all in all, the owners of the mine decided to install a steam power plant, in which the inferior coal is utilized to generate electrical energy, which



CASTELNUOVO-VALDARNO PLANT—EXTERIOR VIEW, SHOWING GENERATOR ROOM AND SWITCH HOUSE.

at 33,000 volts is transmitted over five lines to Florence, Prato, Figline, Siena and Valdarno.

The power plant is located directly beside the mine and the boiler room is connected with the latter by a track. The mined coal is exposed to the atmosphere for some time, after which it is conveyed to the overhead bunkers and fed to the boilers of special design. The conveyors are of the bucket type, and besides handling coal are used to remove ashes.

The boiler house is at right angles to the engine room. It is 180 feet long, 98.5 feet in width, and about fifty-five feet high. There are at present installed ten Babcock & Wilcox water-tube boilers having 5,135 square feet of heating surface each. With a coal consumption of 8,100 pounds, each boiler is capable of evaporating 13,200 pounds of water per hour at 190 pounds gauge pressure.

The engine room is 220 feet long and 69 feet wide. The present equipment consists of three horizontal four-cylinder, triple-expansion Franco Tosi engines, having one high, one intermediate and two low-pressure cylinders. Each has a capacity of 2,600 horsepower and is equipped with Lentz valve gearing.

The direct-connected, three-phase generators are of the British Westinghouse make and have a capacity of 1,800 kilovolt-amperes, making 93.7 revolutions per minute and developing 6,000 volts at fifty cycles. Exciting current is furnished from a common set of buses by two 130-kilowatt, 125-volt, six-pole generators, one being driven by a vertical two-cylinder Delaunay-Belleville engine and the other by a 190-horsepower induction motor supplied with three-phase, 220-volt, fifty-cycle current.

For long-distance transmission the 6,000-volt generator potential is stepped up to 33,000 volts. The equipment of transformers and other high-tension apparatus is among the most interesting features and has been installed by the Maschinenfabrik Oerlikon of Switzerland.

In the accompanying wiring diagram it will be noticed that the ultimate equipment will be seven main generator units, and that the present five main outgoing feeders are arranged symmetrically to the former. Current may be thrown on the 6,000-volt bus-bars or on the transform-

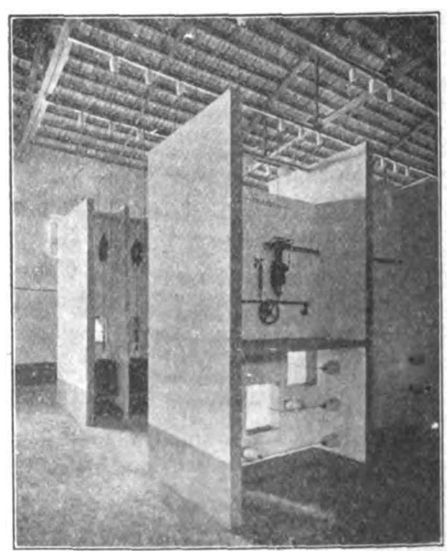
ers direct. The current for the mines and auxiliary motors installed in the power plant is drawn from the generator bus. Auxiliary 6,000-volt buses feed the transformers supplying 220 volts to these vari-



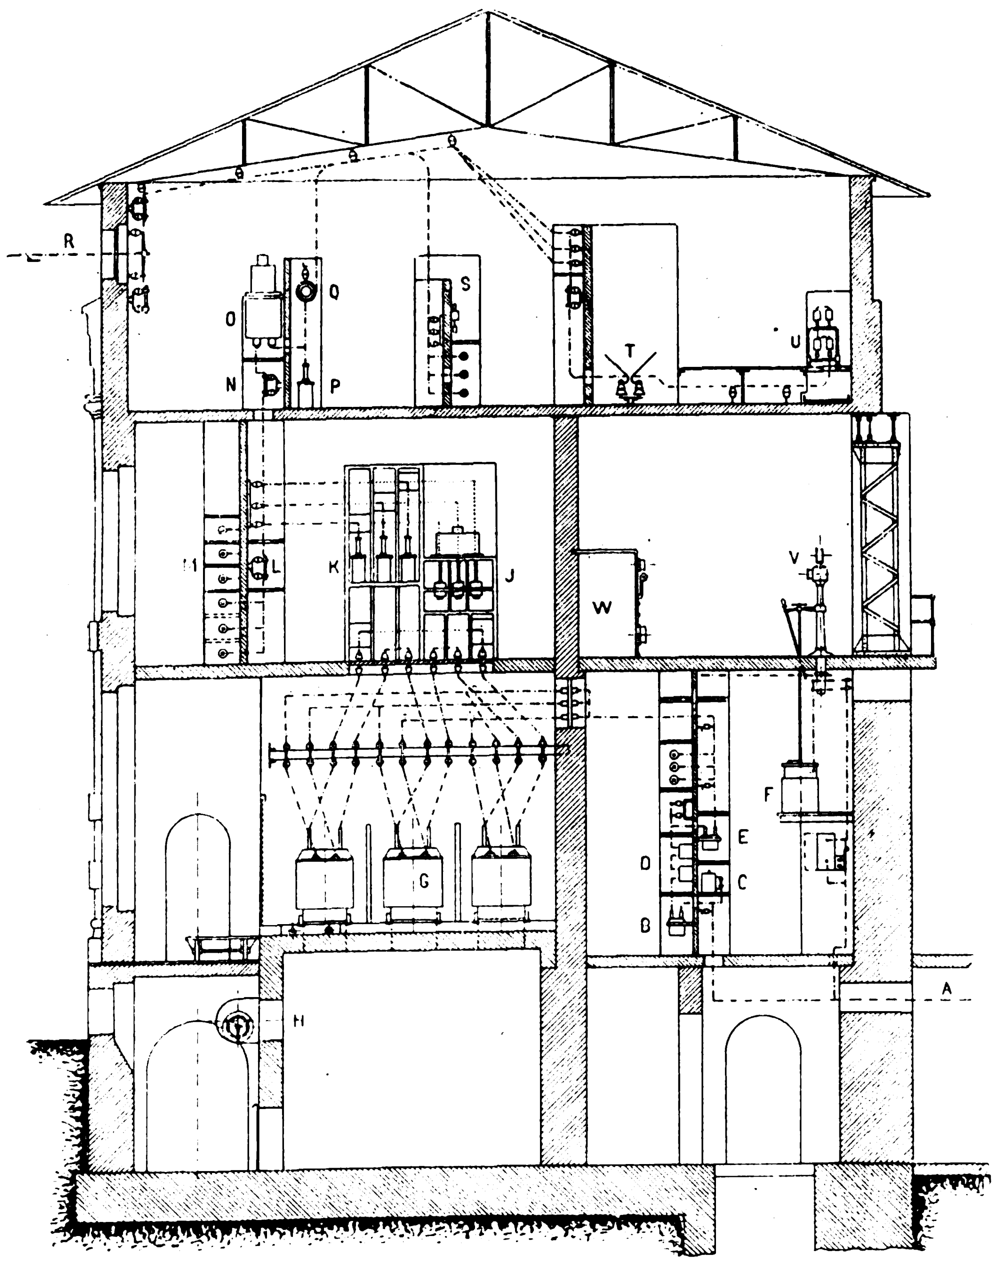
CASTELNUOVO-VALDARNO PLANT—ELECTROMAGNETIC SWITCH AND AUXILIARY BUS FOR GROUND TESTING.

ous motors. The exciter bus will be supplemented in the future by the storage battery indicated.

The 33,000-volt bus is of the ring system, frequently found in continental practice. One thing especially noticeable is the number of sectionalizing switches employed, there being no less than fifteen to accommodate five outgoing feeders. By this scheme each transmission line may be fed by a generator, and in case of necessity may draw from any other generator, or the whole may operate in parallel.

In order to divide the whole bus and main partition wall, separating the two lower floors into high and low-tension divisions.

The 6,000-volt generator switch compartments are located on the main floor nearest the generators. Behind them and on the other side of the partition wall are the 6,000-33,000-volt transformer com-



CASTELNUOVO-VALDARNO PLANT—CROSS-SECTION OF SWITCH HOUSE.

A—Generator leads; B—Automatic overload oil-switch, 6,000 volts; C—Potential transformer; D—Series transformer; E—Selector switch; F—Generator rheostat; G—Transformers; H—Blowers; J—Automatic overload oil-switch, 33,000 volts; K—Series transformer, 33,000 volts; L—Hook switch; M—Busbars, 33,000 volts; N—Hook switch; O—Automatic overload feeder oil-switch; P—Series transformer; Q—Choke coils; R—Outgoing line; S—Ground-detector equipment; T—Horn gaps; U—Water rheostats; V—Instrument column; W—Switchboard.

operate it in two distinct parts each end is provided with series and potential transformers, a voltmeter, three ammeters and one recording polyphase wattmeter.

The switch house possesses many novel features and is one of the most up to date in European practice. This house has, besides the basement, three main floors, which are divided longitudinally by a partments, and above these are the 33,000-volt oil switches and bus-bars. In front of the latter and above the 6,000-volt switch compartments is the controlling room for the generators and high-tension feeders. The upper floor is similarly divided. Above the control room are the protecting devices for the outgoing lines, while in the middle is the ground-detecting equipment, and on the other side are automatic circuit-breakers, choke coils, etc., for the outgoing feeders.

The generator leads are bare conductors carried on ribbed insulators and run to the switch compartments, which are made of reinforced concrete. Each contains a potential transformer for the voltmeter, two for the potential coils of the reverse current relay and polyphase wattmeter, and two remote-controlled oil-switches for throwing the generator on the bus or directly on the transformers.

On the back of each switch compartment is an automatic oil circuit-breaker with a time limit and reverse-current relay, a series transformer for an ammeter, two for the relays and two for the polyphase wattmeter. Referring to the cross-section of the switch house, the arrangement of the switch compartments is indicated by the letters B, C, D and E. Opposite these compartments are the field rheostats located on a shelf indicated by F. They are actuated from instrument columns, V.

The generator instrument columns are arranged in groups of three, between which and in the middle of the gallery are located the columns for controlling the exciters. Upon each generator column are mounted one ammeter for the generator and one for the exciter current, a double voltmeter, a polyphase wattmeter and two pilot lamps for the overload switch. There are also three levers, one for the overload and two for the selector switches.

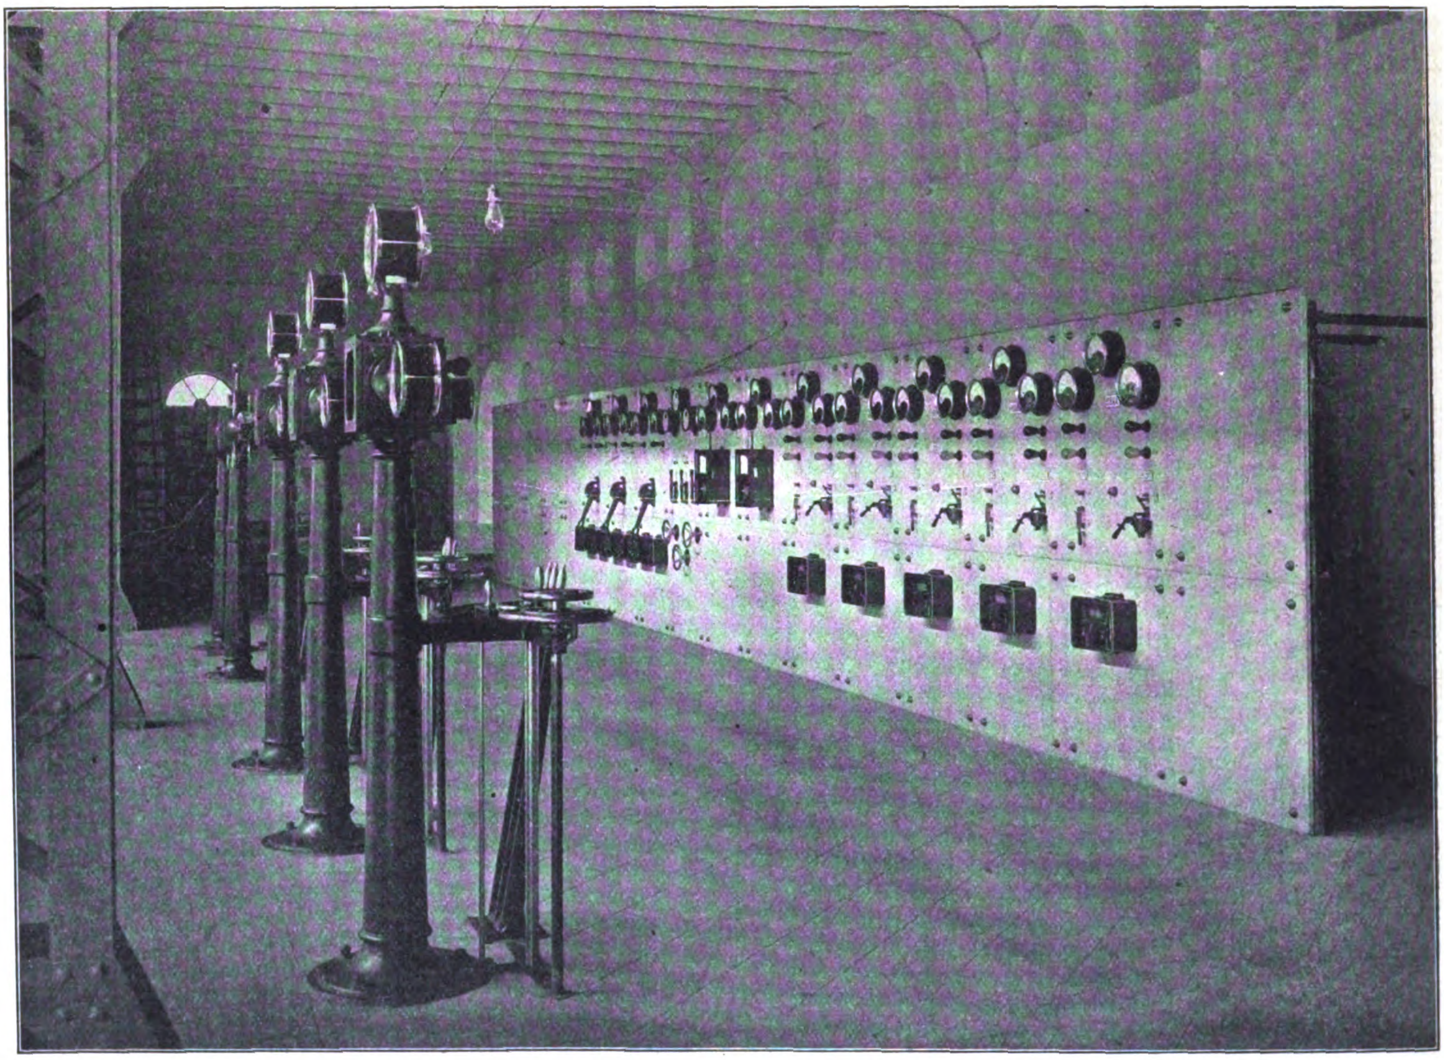
Provision is made by means of a mechanical interlock located between the generator and selector switches, so that when the generator is to be thrown in for parallel operation one of the selector switches must be closed before the main switch, and on the other hand the main switch must be opened before the selector switches.

The exciter current is controlled by two-point carbon switches, operated from the instrument columns by worm gearing. The rheostat for regulating the field of each main generator has two successive contact devices, for which two handwheels are provided on the instrument column. The excitation and main generator switches are so interlocked that the latter cannot be closed when the former is open; on the other hand, the field switch cannot be opened before the main switch. Synchronizing is facilitated by means of a double voltmeter and voltmeter selector switch, so that the voltage and phase of an incoming machine can be compared with those in operation.

Of the two exciter columns, one serves for a future storage battery and the other is provided for each machine with an ammeter, a voltmeter, a handwheel for the automatic overload switch and one for the exciter field rheostat. There are also signal lamps and a starting device for the induction motor.

The transformers are arranged contrary to the usual practice, in groups of three compartment, or three transformers) suspended from a wall of the air chamber in the basement. A novel feature of these transformers is that the core is not surrounded by a casing, but instead the lower half only is surrounded by glass plates.

There are seven compartments for the accommodation of twenty-one transformers, nine of which are at present installed. Another compartment contains four open, air-cooled 6,000-220-volt transformers, each of 250 kilovolt-ampere capacity. pole time-limit relays, are actuated from the controlling board by means of levers, cables and bell cranks. Each transformer group has its own panel on the main control board. Each panel contains a lever for the automatic oil-switch, three ammeters, two signal lamps for indicating the position of the switch, together with a two-pole overload time-limit relay and a two-pole overload reverse-current relay for the generator which belongs to the group.



CASTELNUOVO-VALDARNO PLANT—SWITCHBOARD AND CONTROLLING GALLERY.

in a common compartment, in which they are separated from one another by concrete slabs 6.5 feet high. The ends of the compartments open into a common corridor and are provided with corrugated-iron swinging doors. By means of casters on the transformers they can be moved onto a small truck in the side aisles and the whole conveyed to the repair room.

All the transformers are of the Oerlikon single-phase, air-cooled, open-core-type, connected in delta. Each has a capacity of 600 kilovolt-amperes. The air is supplied to the transformers by means of motor-driven blowers (one for each These serve for the operation of the exciter group and motor pumps for condensing and boiler-feed purposes, as well as for lighting the station. Three of these transformers have their primaries connected in delta and the secondaries in star. The fourth is kept in reserve, and by means of hook switches it is readily cut in.

Instead of being connected in the transformer compartment the high-tension leads run to the floor above, where they are connected in delta, joining here the oil-switches and then the bus-bars. These oil-switches, provided with two-

The feeder automatic oil-switches are provided with overload time relays and are electromagnetically operated from the main control board. Each can be isolated on either side by hook switches. The current passes three series transformers for the ammeters and relays, then through a choke coil and finally through a hook switch out onto the line. Passing under the outlet for each feeder is a common ground bus, which by means of a hook switch is easily connected to each circuit. This arrangement was thought necessary because a number of the substations have synchronous motor-generator sets with storage batteries, and as the sets may sometimes be inverted, being fed by the batteries, there is the possibility that the synchronous motor will feed back into the line.

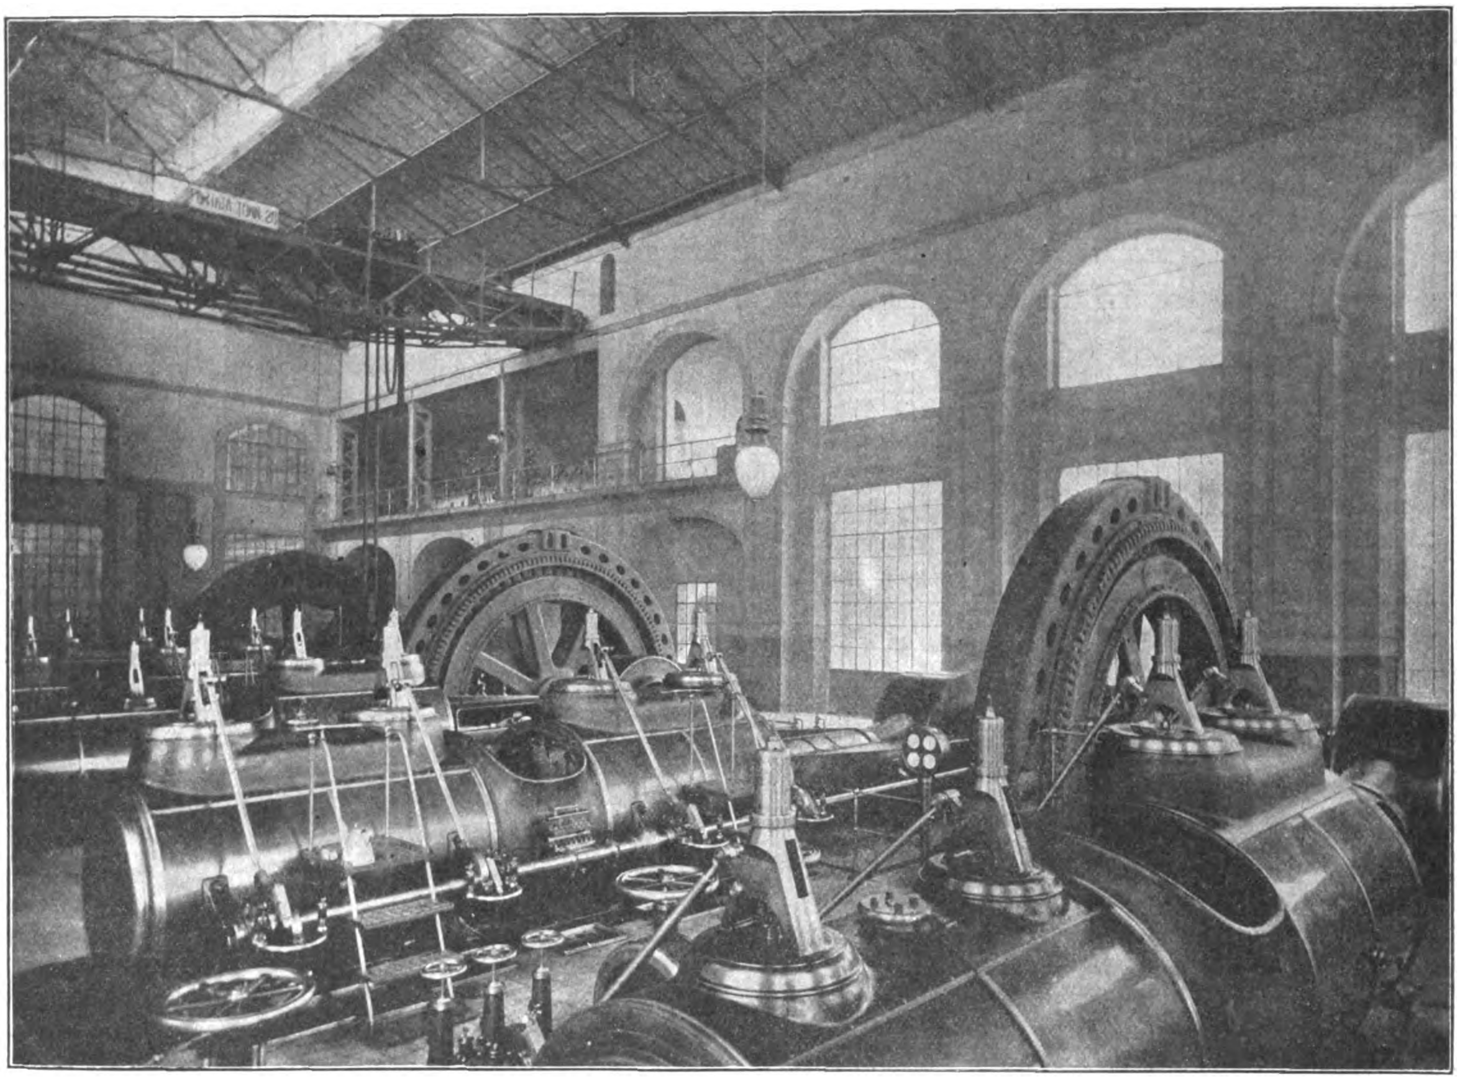
The outgoing circuits are well protected against lightning and other atmospheric discharges. To take care of direct lightning strokes each phase is provided with a horn gap connected in series with four tile water rheostats. The lighter discharges are led off by the Oerlikon water-flow grounders, much used in Swiss and Italian high-tension practice.

There is a very elaborate system for testing the lines for insulation and grounds. It consists of separate auxiliary bus-bars, high-tension oil switches, etc., so arranged that not only can the individual circuits be tested separately, but the phases of the circuits can be tested independently. An electric lock prevents more than one phase from being tested at a time. By means of this equipment the exact location of a ground on a line is readily determined. The method of procedure is as follows: When a grounded line is thrown on the auxiliary bus the ohmmeters give a certain indication. An artificial line is then built up in the station using dry cells. After a few trials the required number of cells to give the same deflection on the ohmmeter as did the line is obtained. As the resistance and other factors of the artificial line bear a certain ratio to the same conditions of the main line, by checking up the elements of the Siemens dry batteries and other factors and multiplying by the ratio the precise location of the trouble is determined.

A separate panel on the main switchboard is set aside for the ground-testing instruments, consisting of three ohmmeters, three single-pole switches for cutting in a battery of seventy-eight Siemens dry cells and a handwheel to facilitate making adjustments.

Each panel for the outgoing lines contains three ammeters, a control switch with two pilot lamps for governing the oil-switches and two-pole time-limit relay, and a control switch with pilot lamps for ground tests. Thorough precautions for safety have been taken. All non-current carrying exposed metal parts, such as brackets carrying insulators, etc., are grounded.

There are at present installed five 33,000-volt transmission lines. One line to Florence is 15.6 miles long; parallel to the same and continuing past Florence is a circuit 30.6 miles long to Prato. Just outside of Florence is a switching station whereby the two lines can be run in parallel as far as the latter city. One line runs southward 16.75 miles to Siena. Another line goes to the iron works at San Giovanni, 3.6 miles distant. Parallel to this and branching off near the substation at San Giovanni runs a circuit six miles long to Figline.



CASTELNUOVO-VALDARNO PLANT—INTERIOR OF GENERATING ROOM.

The transmission towers are of steel lattice construction; the lowest insulator is about forty-five feet from the ground. They are set in concrete blocks which are about six feet deep. The insulators are of the three-piece, triple-petticoat type with a porcelain base, the total being about ten inches high. The head is about nine inches in diameter. They are mounted on wooden brackets with a spacing of thirty inches between the conductors.

In the substation at Florence are installed four 300-kilovolt-ampere, single-phase transformers (one being kept in reserve) to step down from 31,000 to 5,200 volts. The substation has been designed to accommodate twelve transformers. There are also installed two three-phase, fifty-kilovolt-ampere transformers to step down from 5,200 to 260 volts.

The substation at Prato has been designed to accommodate six 300-kilovolt-ampere, single-phase transformers; four of these are at present installed, one being kept in reserve. There are also two fifty-kilovolt-ampere, three-phase transformers. The former step down from 30,000 to 5,000 volts, the latter from 5,000 to 300.

At Siena the substation is designed to accommodate six 300-kilovolt-ampere single-phase transformers, three of which are at present installed.

At the ironworks in San Giovanni there are six 300-kilovolt-ampere, 32,000-3,000-volt, single-phase, oil-insulated, water-cooled transformers. Provision is made for twice as many. At Figline there is but one oil-cooled, 125-kilovolt-ampere, 31,000-3,000-volt transformer.

All these transformers are of the Oerlikon make, and, with the exception of those installed in the last two stations, are of the forced-air-cooled type.

Third Rail for Pennsylvania Tunnel.

The Pennsylvania Railroad Company has announced that it has adopted the direct-current system of electric traction, generally known as the "third rail," for its New York and Long Island tunnel extension. This system of electric traction is now in use on the lines of the Long Island Railroad, with which lines the tunnel extension will be directly connected, and with which it is expected to facilitate suburban development in Long Island and New Jersey.

SMOKELESS COMBUSTION.

BY CHARLES L. HUBBARD.

(Concluded.)

From both an economical and a smoke-suppressing standpoint there are three generally recognized methods for hand stoking a boiler furnace to produce the best results. These are commonly known as "coke firing," "alternate firing" and "spread firing," and have been described in some detail by the writer in a previous article.

Some bituminous coals have little or no coking quality, but will fall into a more or less loose powdery form. Such coal will stand but little moving about on the grate after it has once been charged into the furnace. Other coal when heated will swell up and fuse into a pasty mass, forming a crust on top of the firebed, but after the volatile matter has been distilled from the coal the coke can be easily broken up and moved to any desired position on the grate. Sometimes two such coals can be mixed in such proportion as to give better results than either alone.

Coke firing is best applied to furnaces in which the gases pass over a bridge-wall at the rear of the furnace, or where a brick arch is provided, extending over the firebed for some distance toward the rear. In charging fresh coal into the furnace it is piled inside the door instead of being thrown directly upon the fire, and may occupy about one-third of the length of the grate, extending across the full width. The heat of the furnace will cause a slow distillation of the volatile matter from the coal, and these hydrocarbon gases passing over the incandescent bed of coke in the presence of an abundant supply of highly heated air will be completely consumed. When most of the volatile gases have been distilled from the coal the newly formed coke may be pushed back upon the grate, thus forming a new bed of practically smokeless fuel, and a supply of fresh coal may then be fired in the same manner as before.

After the fireman once becomes familiar with this method of firing in a properly constructed furnace he will be able to secure practically smokeless combustion with no greater difficulty than in the case of any rational system of firing. The economy of this method will vary in different cases, but in nearly every instance will show a saving in fuel. The disadvantages are the length of time it is necessary to keep the fire doors open for charging and cleaning, which allows a large quantity of cold air to rush into the furnace, not only checking combustion but also cooling the boiler parts and causing severe strains. These objections are overcome in various ways as will be described later.

In alternate firing the coal is placed on one side of the furnace at a time, and the result is somewhat like that obtained in the coking system, the gases being burned over the bright side of the firebed as they are given off. After the freshly fired coal has been changed to coke and is burning brightly without smoke the other side of the grate may be fired.

In spread firing fuel should be added at regular intervals, only one or two shovelfuls at a time, and each put where it is most needed. If there are two doors to a furnace, only one should be fired at a time. In other words, fire lightly and frequently. If the work is light and the draft good, smoke may be almost entirely prevented in this way. If the work becomes heavier, fire oftener but do not put on more than three shovelfuls at a time. If much smoke is noticed just after firing, leaving the furnace door ajar an inch or so for about a minute will prevent this.

Having described some of the more important points to be noted in hand firing, let us now consider some of the devices which can be applied to boilers already set without too radical changes.

One of the simplest of these is the steam jet for use when fresh coal is first charged into the furnace. This may be used with the ordinary flat grate and is of great assistance in preventing smoke and promoting combustion generally. The steam jet alone is of very little value, and should always be used in connection with some form of air supply over the fire, as the real benefit derived is not from the steam itself but from the artificial draft which it produces. Immediately after firing, more air is needed than can readily pass through the grate, and if this additional demand is not at once provided the fuel will smoke. If there are two or more steam jets over the furnace door, pointing downward toward the rear of the grate, and suitable air inlets in front or at the side of the grate, the opening of the steam jet will induce a draft and supply the needed air. The supply of steam and air should be gradually shut off as the fresh coal becomes coked. In some patented steam jets or blowers the arrangement is such that the air is drawn in through the blower itself by means of suitable openings provided for this purpose.

The value of any device of this kind depends upon the care which it receives. If of good design and properly used, it should prevent a large proportion of the smoke and at the same time increase the economy somewhat. But if the air-ways become clogged or the tips of the jets are allowed to burn off, or the fireman neglects to turn on steam, the device becomes useless. In order to overcome these objections to some extent, automatic means are often provided, one of which consists of a dashpot which is pushed up by opening the fire door. This in turn opens the valve on the steam jets, opens a hinged flap in the furnace door to admit air over the fire, and closes a check draft in the uptake to increase the draft. As soon as the door is closed the dashpot piston begins to fall and reverses these operations. The time of the falling of the piston may be regulated according to the amount of air needed by the particular kind of coal used. There are several devices working upon the same principle, but differing more or less in detail. It is claimed by some that a steam jet is injurious to the grates and boiler plates; but if the steam and air are well distributed there should be no danger of local injury. The amount of steam used need not be large, as it is only required intermittently, that is, when fresh coal is fired.

The furnaces mentioned thus far have been fired by hand and depend largely for their success upon the skill and faithfulness of the fireman. Briefly, the directions given may be summed up as follows: Keep the fires clean and bright and do not allow the grates to become clogged; carry as thin a fire as is sufficient for the work to be done, but do not allow air-holes to form; put on coal in small quantities (unless the coking system is employed) and as often as may be necessary, spreading it thinly and evenly, so that it may burn brightly at once; in cleaning do not tear the fire to pieces and uncover large spaces of grate, but clean one side at a time and cover the grate with red-hot fuel before putting on fresh coal; keep all flues and heating surfaces clean, and when firing heavily leave the doors slightly ajar for a couple of minutes or so after firing.

If, after improving the conditions by more skillful firing, it is desired to take a more radical step toward the elimination of smoke, one of the reliable forms of automatic stoker should be installed, which, with proper care and adjustment, should be able to furnish steam to the full capacity of the boiler without an objectionable amount of smoke. The reason for their superiority over hand firing depends principally upon their uniform action and the avoidance of opening the fire doors for the introduction of fuel. The stoker feeds the coal to the fire regularly instead of intermittently, and the air supply can be easily graduated to correspond. When a stoker produces smoke regularly it is usually due to the fuel not feeding forward properly, and to its clogging and sticking to the bars. Either the stoker, the fuel or the fireman may be at fault for this condition; the stoker by improper shape and setting of its grate, the fuel by melting and forming clinkers, and the fireman by not adjusting the stoker to the fuel used.

Mechanical stokers may be divided into three general classes, as follows: Those with rocking or shaking bars placed in an inclined position, traveling or chain grates, and under-feed stokers.

The first type is unsuitable for burning a coking coal, the only satisfactory fuel in this case being one which burns freely, forming a light ash and little clinker. Stokers with inclined grates have not always given the best satisfaction as smoke preventers on account of the fuel sticking to the top of the grate and leaving holes in the fire below. This makes it necessary to poke the fire from time to time, which is liable to result in rolling considerable masses of burning fuel to the bottom of the grate, and carrying more or less unburned coal with it.

Chain-grate stokers are particularly well adapted to large plants carrying a uniform load, and have the advantage of being self-cleaning and are very efficient in the prevention of smoke. They usually consist of an endless chain having a width equal to that of the furnace, running over sprocket wheels at the front and rear. The coal is fed onto the grate at the front and the ash is dumped over the rear end.

Under-feed stokers rank next to chain-grates in the prevention of smoke, being practically smokeless except at the times of cleaning the fire or when the side doors are open.

In addition to mechanical stokers, there are several furnaces of special design which give very good results. One of the most successful in smoke prevention and economy is the so-called down-draft furnace, which is built on the principle of a kerosene lamp. The coal in this furnace burns from the bottom, that is, the flame is led away from the fuel just as with a candle or lamp.

The gases are thus distilled slowly and afforded an opportunity to come in contact and mingle with the proper amount of heated air. The upper grates supporting the fire must, of course, be water grates, otherwise they would be burned. Below the water grate is a common grate for catching and burning the coke which falls through the upper grate when the fire is sliced. In this furnace the excess of heated air which passes through the lower grate is necessary for complete combustion of the hydrocarbons which may pass through the water grate with a deficient amount of air. With this form of furnace an almost entirely smokeless chimney and a considerable gain in economy can be obtained if handled with a reasonable amount of intelligence.

Another form of special furnace has a grate made up of two parts, the forward part being stationary and sloping moderately from the fire doors toward the dumping grate at the rear. A fire-brick arch is built across the center of the furnace over the rear grate. Fuel is fired upon the front or sloping grate and after the gases have been given off it is pushed back upon the dumping grate. Air is admitted through both grates from the ash-pit and also above the fire through a special opening in the front wall. The arch serves to deflect the air and gases downward toward the incandescent coke upon the dumping grate, which insures complete and smokeless combustion if proper care is used in firing.

Another form differs from the ordinary furnace in having two vertical walls, with a narrow opening between them, built back of the bridge wall near the end of the boiler. In addition to these, there is a fire-brick arch over the combustion chamber and a series of short walls or piers back of the bridge wall. Coal is fired alternately upon one-half of the grate at a time and the smoky gases from the freshly fired side and the excess of very hot air passing through the bed of bright coal on the other side are brought together by passing through the narrow opening between the two vertical walls, and combustion is therefore made much more complete.

One important matter in the design of a furnace for smokeless combustion is to obtain the proper area of grate surface to burn the fuel used to the best advantage. First, the particular kind of coal to be used should be selected, and then the rate of combustion determined. This will vary for different coals. A writer in *The Engineer* gives the following, based upon a series of tests, as giving average results:

Kind of Coal.		Pounds Burned per Square Foot of Grate per Hour.
Anthracite	Steam sizes	15
Semi-anthracite		16
Semi-bituminous		18
Eastern bituminous		20
Western bituminous		30

It is an important matter to have the grate bars properly spaced to give room for the air to pass to the fuel bed and combustion chamber beyond it. If an excessive amount of ash occurs in the fuel used, shaking grates should be used (if hand fired), so as to easily keep the air openings clear, and thus facilitate the passage of air through the grates and fuel.

In drawing up smoke ordinances it is necessary to state what degree of density constitutes an offense. It will be found in practice that a certain latitude must be allowed, as there are usually periods of two or three minutes in the case of hand-fired boilers when smoke will be emitted from the chimney, and it is well in framing such an ordinance to state that smoke above a certain degree of density will not be permitted for periods of over a given length of time.

There are several ways of determining the density of smoke; the one most commonly used at present is known as the Ringelmann Chart. This is composed of six rectangles, the first being perfectly white, while the sixth is entirely black, and the intermediate rectangles placed between these two extremes have a series of black lines ruled upon them at fixed distances apart, as indicated below:

No.	Black Spaces.	White Spaces.
0	....	All White
1	1 m. m. wide	9 m. m. wide
2	2.3 m. m. wide	7.7 m. m. wide
3	3.7 m. m. wide	6.3 m. m. wide
4	5.5 m. m. wide	4.5 m. m. wide
5	All Black.	....

This chart is placed between the observer and the chimney, and at a distance of some fifty feet it will be seen that the ruled lines upon the rectangles are blended together to form a succession of tints, so that the observer may compare the tint of the chart with the gray or black smoke as it issues from the chimney.

In Australia a telegram is carried 3,000 miles at the rate of two cents a word across the territories of six governments and states.

INDEPENDENT TELEPHONE CONVENTION.

THE CLOSING SESSIONS—THE EXHIBITS.

The twelfth annual convention of the International Independent Telephone Association, held in Chicago during the week of December 1, was brought to a successful close after a belated session on Thursday afternoon, when the final business and election of officers was finally transacted. The convention was marked by lively interest and general attendance on the part of the delegates, representing "four million telephones and seventeen million users," and the manufacturers of Independent telephone apparatus were on hand with an instructive array of equipment and exhibits estimated at a total value of about $50,000.

As reported in full in the ELECTRICAL REVIEW AND WESTERN ELECTRICIAN of last week, the three sessions of Tuesday were given over to preliminary business and the consideration of certain important technical matters. On behalf of Mayor Busse, George M. Bagby, assistant corporation counsel for the city of Chicago, welcomed the members of the convention, and his cordial words were given a pointed response in the reply of R. D. Critchfield, president of the Wisconsin Telephone Associaton, who urged upon the city administration the importance of telephone connection with the large majority of Independent subscribers in the vicinity of Chicago.

Tuesday afternoon was devoted to technical discussion relating to local line operation. Roy Owens, of Columbus, Ohio, presented a paper on "The Telephone Engineer in His Relation to the Telephone Business." J. H. Ainsworth, of Dayton, Ohio, discussed "Some Economies in Handling Maintenance Men." G. E. Bickley, of Waterloo, Ia., read a brief paper on "Maintenance Economies." J. P. Boylan's paper on "Handling Trouble" was read by B. H. Brooks.

At the evening session matters of interest to toll-line operators were taken up. Frank F. Fowle, consulting engineer, Chicago, delivered, in abstract, his exhaustive paper on "The Economical Development of Toll Territory." George K. Gann, Lincoln, Neb., related in brief the contents of his paper, "Handling Long Distance Traffic." Both afternoon and evening technical discussions were in charge of Gansey R. Johnson, of Columbus, Ohio.

The early part of the session of Wednesday morning was given over to the reading of the reports of various state and local Independent telephone associations, affording a favorable account of the progress of the Independent movement throughout the country. The convention then listened to the paper on "The Supply and Preservation of Poles," by W. F. Sherfesse, an expert in the employ of the Forest Service.

ANNUAL CONVENTION OF THE INTERNATIONAL INDEPENDENT TELEPHONE ASSOCIATION, AUDITORIUM HOTEL BANQUET HALL, CHICAGO, ILL., DECEMBER 2, 1908.

Mr. Sherfesse spoke of the relative advantages of the preservatives used in the prevention of the decay of wood. These are corrosive sublimate, copper sulphate, zinc chloride and creosote. The first two are being supplanted by the latter in the preservation of telephone-line material. Zinc chloride may be painted over, but has the disadvantage of being soluble and will bleach out of the wood. Creosote has a higher first cost and possesses the added disadvantage of a rather limited supply.

The preservative treatment of impregnation may be carried out in the presence of either artificial or natural pressure. The pressure treatment involves first subjecting the wood to a steam bath, then exposing it to a partial vacuum, to exhaust the moisture and air from the pores and cellular interstices, and finally applying oil under pressure. This treatment is giving way to the "open-tank" treatment of the butt, which requires less expensive apparatus and is simpler to effect. Air-dry wood is placed in an open bath of hot oil. The oil is then cooled, or run out and its place taken by cold oil, or the wood is removed and plunged into a receptacle containing cool oil. The preserving compound penetrates the sapwood easily, but longer duration of the treatment is required for its effective entrance into the heartwood.

The benefits of the preservation treatment are manifested by the increased life given to the ordinary run of timber, and the possibility of use of a cheaper grade of wood otherwise entirely unsuitable. Thus, southern loblolly pine can be treated and made useful for telephone purposes, and fire and insect-killed timber becomes as available as that thoroughly seasoned.

Business and financial matters of Independent telephone operation were discussed during the session of Wednesday afternoon. "Damage Suits—Their Prevention and Defense" was the subject of a paper by William S. Hart, an attorney of Waukon, Ia. C. E. Wilson, of Philadelphia, Pa., read a paper on "Pernicious Political Pull" and J. B. Hoge, Cleveland, Ohio, presented the matter of "Insurance—Liability and Fire."

The programme of the afternoon session was interrupted by the committee on finance, which issued a call for funds to carry on the campaign of education and legal enactment in the interest of the Independent telephone movement. Following the call, the convention scene was an enthusiastic one as the delegates rose in quick succession to pledge duplication of the subscriptions of state associations, companies and individuals for the year before, or to increase or propose new amounts. Under the active invitations of James S. Brailey, Jr., chairman of the finance committee, in an incredibly short time the total amount subscribed reached $95,000.

At the annual association banquet, held at the Auditorium Hotel in the evening, the following toast list was given, with Dwight E. Sapp of Mt. Vernon, Ohio, presiding at the speakers' table:

"The Telephone President." H. D. Critchfield, Milwaukee, Wis.

"The Crowning Triumph." W. S. Hart, Waukon, Ia.

"Mergers and Alliances." D. J. Cable, Lima, Ohio.

"Competition versus Monopoly." Judge C. W. Showalter, Parkersburg, W. Va.

"The Telephone and the Law." Clarence Browne, Toledo, Ohio.

"Our Emblem." Manford Savage, Champaign, Ill.

On Thursday morning, following the reading of the reports of the remaining state and local associations, Secretary Ware read the paper on "A Sound Financial Policy," by E. B. Fisher, Grand Rapids, Mich.

"Some Telephone Problems" was the title of a paper by Morgan Brooks, professor of electrical engineering at the University of Illinois, which received the interested attention of the convention.

Success in the telephone field has been due to the engineer rather than the inventor, premised the writer. He then directed attention to the priority of use of the telephone induction coil over the transformer for the transmission of electric currents to great distances. Professor Brooks reviewed briefly a number of problems of construction, the matter of "loading" long lines, and the increasing danger and annoyance from high-tension power lines near telephone circuits. The advent of the single-phase alternating-current railway has brought in a large share of troubles which simple expedients of transposing or insulating the telephone line have been unable to remedy. A three-phase high-tension power transmission system carrying a balanced load creates only a slight disturbance, since the wires are comparatively close and the sum of the currents in any two wires at any instant is equal to that in the third. However, the single-phase railway employing a single conductor of comparatively high voltage (3,300 to 6,600 volts) with a ground return, introduces conditions of noise and even dangerous induced potentials which cannot be well avoided without removal of the telephone wires outside of the disturbing zone.

The engineering experiment station of the University of Illinois, said Professor Brooks, is now building an experimental line, paralleled by power wires, one mile in length, and arranged so that any required conditions can be obtained. That actual danger exists to men working a telephone line near a high-tension circuit, Professor Brooks cited a laboratory experiment in which an insulated wire five feet away from a 6,000-volt line showed an induced potential of 500 volts. While this represented only the slight static charge of the line, the capacity of the wire being, of course, very small, the professor believed that a long line under certain conditions might deliver a fatal current. The improving insulation of telephone lines of course tends to conserve the charge, and with improved conditions in this direction the danger from induced shocks is increasing. A telephone line within 200 or 300 feet of a single-phase trolley line will likely be rendered inoperative, and the effect of the alternations has been noticed at a distance of several miles.

Following Professor Brooks' discussion of high - tension alternating - current sources of annoyance and danger, Secretary Ware read a paper on "Western Electric versus Independent Telephone Apparatus."

At the afternoon session a number of committee reports were heard and before the convention was finally declared adjourned the following officers were elected: President, E. H. Moulton, Minnesota; first vice-president, P. C. Holdoegel, Iowa; second vice-president, E. B. Fisher, Michigan; treasurer, Manford Savage, Champaign, Ill.; secretary, A. C. Davis, West Virginia.

Directors for one year: A. E. Boqua, Arkansas; J. W. Barnes, West Virginia; M. L. Colladay, Missouri; P. H. Griswold, New York, and A. E. Yaxlor, Illinois. For two years: F. D. Houck, Pennsylvania; Frank C. Hoge, Kentucky; W. H. Nelson, Kansas; Dr. J. E. Demers, Canada, and H. D. Critchfield, Wisconsin. For three years: Frank L. Beam, Ohio; Manford Savage, Illinois; James H. Shoemaker, Iowa; Charles B. Norton, Indiana, and E. B. Fisher, Michigan.

The next convention will be held in Chicago in December, 1909.

A direct outcome of the Independent telephone convention in Chicago is the amiable consideration given by the city administration to the matter of long-distance connection with the large proportion of Independent subscribers in the adjoined states.

A committee from the telephone association held a conference with the council committee on gas, oil and electric light, which resulted in the association being requested to submit a concrete proposition at an early date.

A. C. Lindemuth of Chicago went into details regarding the proposed service before the council committee, and in reply from queries from Aldermen Pringle and Snow, gave data regarding the operations of the Bell company. The committee for the telephone association was told that a local service might not be considered at this time, but that a long-distance service, built along the lines proposed by Mr. Lindemuth, might be accepted by the council.

EXHIBITS AT THE TELEPHONE CONVENTION.

The North Electric Company, Cleveland, Ohio, presented one of the most interesting and novel of the exhibits in the shape of a section of the new Clement Automanual switchboard it has begun to install at Ashtabula, Ohio. The Automanual system, as the name implies, combines certain features of both the manual and automatic switchboards. As explained in a circular given out by the North company, any standard common-battery subscriber's instrument can be used in the new system, as the subscriber calls in the usual way, verbally, giving the number wanted to the operator, who sets it up on a keyboard similar in appearance to that of an adding machine. From this point the operation of selecting a trunk, connecting and ringing the called subscriber is all performed automatically. Immediately the operator has set up one call she is ready for another, and the calls are automatically distributed among the positions, the simple duty of the operators being to set up the numbers. Clearing-out is automatically effected by hanging up the receivers. Edward E. Clement, the inventor of the Automanual system, was present and answered the questions of a great many interested inquirers.

The Sandwich Pole-Changer Company, Sandwich, Ill., showed an operating exhibit of its product which is adapted to supply either alternating or pulsating current. The three contact springs are provided with heavy platinum contacts, and in other respects the Sandwich pole-changer is of extremely rigid and compact construction.

Stanley & Patterson, New York, N. Y., showed a number of sections of the Patterson wireless dry-battery holder, with the special form of dry cell adapted to fit in this convenient holder. One of these types of cell is provided with both the standard binding posts and the screw-thread contacts. The Patterson holder is made with an automatic bridge which restores the continuity of the circuit if any cell is removed.

The Everstick Anchor Company, St. Louis, Mo., showed a number of anchors made on its well-known mechanical principle, so arranged that after the anchor is inserted in an eight-inch hole it may be tamped to expand its plates out into the undisturbed earth.

The Miniature Telephone Booth Company, New York, N. Y., demonstrated two popular forms of its telephone container by the use of which one may secure the utmost privacy in the use of his instrument without actually entering a sound-proof box.

Middleton Bros., Monadnock Block, Chicago, gave practical demonstrations and instruction in the use of testing instruments for locating telephone troubles. The Universal test set was used in these demonstrations.

The Dayton Telephone Lock-out Manufacturing Company, Dayton, Ohio, exhibited the Kneisly-Billman lockout for use on party lines. The hook switches of any subscribers on the line, not called, are effectually locked down until released by the central operator with this system.

The Duplex Metals Company, New York, N. Y., had an interesting exhibit of Monnot copper-clad steel wire, which is manufactured in a variety of forms and sizes for telephone and electrical use. The two metals are welded with a perfect autogenous joint, and the wire combines with the strength of the steel the superior conducting and non-oxidizing properties of the copper covering.

The Baird Manufacturing Company, Chicago, showed its new Baird chronograph. Any number of toll tickets may be "started" in this machine and then "finished" in any order whatsoever, while the machine will print on each the actual duration of the call as well as the time and date.

The Holtzer-Cabot Company, Brookline, Boston, Mass., made a very complete demonstration of its new and leading products. One of these is its new four-frequency multicycle vibrating converter. Another is its composite multicycle motor-generator set. For use with these there is a frequency meter which operates on an escapement principle. A full line of pole-changers, switchboard and telephone parts made up the rest of the exhibit.

The Excelsior Supply Company, Chicago, exhibited two handsome Excelsior autocycles, which are coming to be used to an increasing extent by telephone men in going quickly to the scene of line and other trouble.

The Universal Specialty Company, Terre Haute, Ind., offered a few suggestions on the construction of telephone drop circuits by the use of its Universal insulators adapted to carry two wires.

The Stromberg-Carlson Telephone Manufacturing Company, Rochester, N. Y., held the interest of the operators of magneto exchanges with its self-restoring gravity drop and magneto switchboards.

The Homer Roberts Telephone Company, Chicago, Ill., had a number of operating lines of its local-battery party-line system, on which calling is accomplished by lifting the receiver off the hook, as in a common-battery exchange. By an emergency arrangement the subscribers' signaling means is always available, whether his own or any other instrument is in use, so that the line cannot be effectually tied up by any subscriber.

The Illinois Electric Company, Chicago, made a feature of its exhibits of pole seats and circle tops. The latter is somewhat of an innovation in distributing circles, as the entire ring, twenty-one inches in diameter, is of gaspipe covered with circular loom.

The Indiana Steel and Wire Company, Muncie, Ind., exhibited its extra double-galvanized telephone and telegraph wire.

The Fibre Conduit Company, Orangeburg, N. Y., was represented by W. W. Smythe, Jr., western manager, and had on exhibit all sizes of the socket-joint type of Orangeburg fiber conduit as well as its thin-wall-type linaduct and distributing-pole bends and reducers. Sections of four-duct subway showing these products installed in concrete were also shown.

The Automatic Electric Company, Chicago, took the occasion of the Independent telephone convention to introduce its new dial-type of instrument as well as its small calling switch which can be applied to any common-battery set. The Automatic Company operated a complete exchange with a number of instruments equipped with automatic ringing, doing away with the necessity for the calling subscriber's pressing the button.

The American Electric Telephone Company, Chicago, showed a full complement of its line of switchboards, telephones and parts.

The Century Telephone Construction Company, Buffalo, N. Y., manufacturer of switchboards, telephones and parts, occupied Room 628 with an exhibit.

The Chicago Telephone Supply Company, Elkhart, Ind., had rooms 420 to 426 inclusive for its exhibition of telephone apparatus.

The Cracraft-Leich Electric Company, Genoa, Ill., demonstrated the telephones and switchboards of its well-known make.

H. E. Cobb, Chicago, occupied a room on the parlor floor of the Auditorium Hotel with rubber-covered and galvanized wire, general supplies and protective devices.

Frank B. Cook, Chicago, showed some of the latest of his large line of telephone protective apparatus.

The Corwin Telephone Manufacturing Company, Chicago, exhibited intercommunicating switchboards.

W. H. Couch, Boston, Mass., showed a general line of telephone apparatus.

The Dean Electric Company, Elyria, Ohio, made a feature of its harmonic ringers in addition to its general exhibit of switchboard and telephone parts.

The Electric Appliance Company, Chicago, made an exposition of general telephone supplies.

The Fox & Borden Manufacturing Company, New York, N. Y., showed a number of telephone specialties in Room 647.

The H. S. Green Battery Company showed batteries.

Frederick Grier, president, and A. L. Hasse, sales manager, of the Harvard Electric Company, were in daily attendance at the convention.

J. Wiley, of the Standard Underground Cable Company, was a prominent figure among the manufacturers' representatives.

The Manhattan Electrical Supply Company, Chicago, exhibited small power devices.

The Miller Anchor Company, Norfolk, Ohio, demonstrated its expansible anchors for guying.

The Monarch Telephone Manufacturing Company, Chicago, exhibited telephone instruments and switchboards on the convention hall floor.

The Ohio Brass Company, Mansfield, Ohio, had an exhibit of line material.

The National Carbon Company, Cleveland, Ohio, interested the local-battery telephone men with its exhibit of dry cells.

F. W. Pardee, Chicago, showed batteries, wire, receiver shells and cable reels.

The Pierce Specialty Company, Elkhart, Ind., made an exhibit of telephone construction material.

The St. Louis Malleable Casting Company, St. Louis, Mo., showed a number of telephone specialties.

The Sterling Electric Company, Lafayette, Ind., occupied the hotel writing room with a diversified array of the apparatus of its manufacture and exhibited as a rather novel departure a compressed-air and vacuum cleaning system.

The Swedish-American Company, Chicago, showed a complete exhibit of telephones, switchboards and parts.

The Vote-Berger Company, La Crosse, Wis., demonstrated the simplified common-battery exchange circuits made possible by the use of its well-known ballasted lamp. In series with an iron ballast the lamp is placed directly in the line circuit, and on account of the temperature coefficient of the ballast the lamp will come to approximately the same brightness over a considerable range of impressed voltage.

The Warner Electric Company, Muncie, Ind., exhibited a complete line of the well-known Warner pole-changers.

The Westinghouse Machine Company, Pittsburg, Pa., exhibited storage cells of interest to common-battery men.

The Wireless Cable Tester Company, Cedar Rapids, Iowa, had a representative on hand with some faulty cable and by means of a tone-test and exploring coil located the "bug" promptly.

The Influence of High-Tension Lines on Hailstorms.

In a paper before the French Academy of Science, Mr. von Fagniez recently presented evidence of the effect of a three-phase, 45,000-volt line on a hailstorm.

A hailstorm, introduced by a few ball-lightning strokes, followed the course for 8.5 miles. The high-tension line runs parallel to a chain of mountains some two miles away. Previous to the construction of the transmission line, observations established the fact that the mountain chain attracted hailstorms. This is explained, in that the numerous cross valleys diverted the route of the storms so that they followed the main chain.

Contrary to former observations (the line has been in existence about a year), the hailstorm jumped over all cross valleys and followed the course of the transmission line.

The members of the Academy of Science agreed that the storm was influenced by the high-tension line, but were undecided whether the line was the direct cause of the hailstorm.

Western Electric Annual Report.

The annual report of the Western Electric Company for the fiscal year ended November 30, 1908, will show gross sales for the year, running close to $36,000,000, as compared with gross sales of $52,724,168 for the previous year. In 1907 the Western Electric Company earned $1,217,000 applicable for dividends, paying $1,200,000, or eight per cent, on its capitalization of $15,000,000. The economies effected by the company in operating expenses and the reduction of its floating debt and bills and accounts receivable, from the large amounts of former years, will, it is believed, enable the company to declare seven per cent dividends, if not the rate of the previous year.

October is the best month so far this year, and orders were booked at the rate of $44,000,000 a year. November shows the greatest increase in new business, according to the *Wall Street Journal*. One in close touch with the company's affairs says:

"The electrical business has shown a decided improvement during the last few months. Contracts and new developments, held up on account of financial stress, are now being placed under way again, but we look for the greatest improvement to come after the first of the year. The electrical supply business is the most active branch at the present time. We are also meeting with considerable success in demonstrating a low-pressure turbine which will be placed on the market shortly. During the slack times we conducted a more aggressive educational and sales campaign than ever before. Our advertisements appear in seventeen leading periodicals and numerous electrical and machinery trade papers, and we are getting excellent results both in inquiry and orders booked."

There is now little likelihood that the $15,000,000 five-per-cent bond issue, which was authorized some time ago, will come to light in the immediate future, as the conditions which seemed to make the bond issue necessary no longer exist. The bills and accounts receivable item which, for the year ended November 30, 1906, reached the large total of $24,555,074, was reduced to $18,252,060 in the year ended November 30, 1907, and this year's report will show as great a rate of decrease over the preceding year. The floating debt of $11,500,000 for 1907 is now in the neighborhood of $5,000,000, and as the last report showed quick assets of $21,025,669 and a surplus of $18,252,060, a bond issue is not imperative.

Train Dispatching by Telephone.

The use of the telegraph as an instrument for the dispatching and operation of trains on American railroads will soon become obsolete as the result of a recommendation made by a committee at the recent Chicago meeting of the American Railway Association, which represents over 240,000 miles of railroads.

After an investigation extending over nearly a year by a committee appointed to consider the subject it has been found that the telephone is not only as safe as the telegraph for directing the movement of trains but is more efficient and economical. Therefore the railroads are advised to substitute the newer system for the telegraph gradually.

This has already been done on a large number of roads with marked success on steadily increasing sections of their lines. Railroads running out of Chicago have already installed the telephone on over 3,000 miles of line, and as a result of the decision of the association the installations will be rapidly extended. The two systems have been used side by side in many cases, as the same wires can be used for both, but the investigation of the committee has shown that the telephone is so far superior that there is little object in retaining the telegraph except for commercial purposes. The main advantages, according to the committee, are in the saving in time and in the fact that the telephone can be used by anyone.

The investigation of the possibilities of the telephone and the decision to recommend it as a standard instrument are largely the direct result of the workings of the nine-hour law. This made it necessary for the roads to have three instead of two operators at many stations, and to employ 8,000 additional men, increasing their expenses by over $10,000,000 a year. As the Order of Railway Telegraphers has refused to allow its members to instruct student operators it was in many cases difficult to secure the new men, and the roads immediately turned to the telephone as a possible remedy for the situation.

North Shore Electric Officers.

The annual meeting of the North Shore Electric Company, operating in the suburban belt surrounding Chicago, was held November 30. Directors were re-elected as follows: Samuel Insull, Charles H. Randle, Charles F. Spaulding, Edward P. Russell, William A. Fox, Louis A. Ferguson and Frank J. Baker.

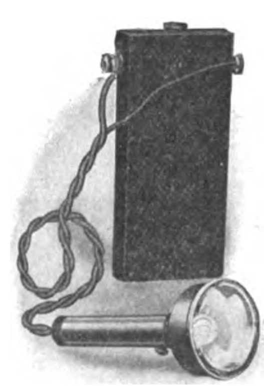
There was represented at this meeting 28,604 out of a total of 29,896 shares.

Electric Head Lamps for Chicago Street Sweepers.

To protect its night workers and sweepers against being run down by the many automobiles which dash rapidly through

STREET CLEANER EQUIPPED WITH ELECTRIC LAMP.

Chicago's boulevards and parkways the South Park Commission has equipped its scavengers with electric head lamps, as shown in the accompanying photograph. The unusual spectacle of these brilliant



PORTABLE ACCUMULATOR AND USUAL FORM OF FLASH LAMP.

little lamps bobbing across the highways in the stretches between the park lights has attracted the curiosity of all who see them for the first time. The lamps are serving their purpose effectively and are a source of very evident pride to their humble wearers.

A two-volt tungsten lamp arranged in a special socket for mounting on the hat of the wearer derives its current from a single pocket storage cell rated at six ampere-hours. This is sufficient to maintain the little lamp from twelve to fifteen hours on a single charge, it is asserted. The storage battery uses lead plates and an electrolyte of so-called "solidified" sulphuric acid, giving a compound of the consistency of table jelly. The cell is about an inch in thickness and measures two and three-quarters by six and one-half inches. It weighs one and one-half pounds.

The charging rate of the cell is one-half ampere, requiring twelve hours for a complete charge. The cell is conveniently charged from a 110-volt direct-current circuit by inserting it in series with an ordinary sixteen-candlepower incandescent lamp.

The outfits, with the exception of the special socket arranged to be fastened on top of the hat, are similar to those used by workmen in oil and gas works, paint factories, etc., and by watchmen, and were furnished by the Vesta Accumulator Company, 1336 Michigan Avenue, Chicago.

Long Trip in an Electric Automobile.

Oliver P. Fritchie, president of the Fritchie Automobile and Battery Company, of Denver, Colo., completed a trip of 1,800 miles, from Lincoln, Neb., to New York city, in an electric victoria of his own manufacture, on Saturday evening, November 28. Mr. Fritchie arrived at the Hotel Knickerbocker, in Times Square, after having been on the road just twenty-eight days.

The motor on the car has a maximum output of ten horsepower, and is geared up to nineteen miles an hour. On one charge it will travel about 100 miles, although on one day it is stated that this distance was exceeded by twenty-five miles, when Mr. Fritchie drove from Toledo to Wooster on one charge. The shortest run was over the blue-clay roads of Iowa, which were sticky and slippery from bad weather, when only forty-five miles was covered.

Although the trip establishes the fact that, under certain conditions, an electric car may be relied upon to travel 100 miles on one charge, it is the opinion of Mr. Fritchie that this record could not be made in an ordinary electric car unless it was handled by an expert electrician.

Proposed Modern Power Plant for India Coal Fields.

Writing from Calcutta, United States Consul-General William H. Michael says that many of the India collieries will have to put in new machinery, some of them complete new equipment, and that to meet this need a company has been organized in Calcutta called the Coalfields Power Syndicate, with a capital of $700,-000.

The object is to provide cheap power for coal-mining purposes. The prospectus of the company says that ten per cent of the coal mined in India is consumed at the mines for power, which for 1907 would be a consumption of 915,296 tons, worth $3 per ton.

It is to try and greatly reduce this unnecessary expenditure that the company has come into existence. It is proposed to sell electrical current at one anna (two cents) per unit, and besides power the company will handle up-to-date colliery equipment, kept in stock, in order to meet any emergency. It is believed that the gross revenue will be $113,666 for sale of power and $31,150 from rentals of colliery equipments. In reference to the need of such a syndicate, the prospectus says:

At the present time many collieries have to face an early replacement of much of their plant, and it is partly owing to this that the present demands on the syndicate for power are so large. It is only since the construction of the railways that the coal fields have been seriously worked, and although the progress for many years was slow, the development has been extremely rapid of late, as the following table of coal raised in Bengal will show:

Year.	Persons Employed.	Output in Tons.	Number of Companies.	Capital.
1904	14,896	7,058,980	28	$6,964,366
1905	33,496	7,234,103	33	7,916,152
1906	36,194	8,677,820	37	8,448,517
1907	39,365	9,993,348	77	15,358,000

The above table shows that the number of companies and their capital employed in coal mining increased very slowly until 1907; since then the expansion has been very rapid, but, as will be noticed from the column of output, there has not yet been time for the new companies to develop their mines, and a large part of the increased capital is therefore not yet productive. A natural result of this expansion is the shortage of labor from which the coal fields are now suffering, and which is considerably restricting the operations of fully developed mines. In fact, as shown in the table, the number of miners available has not kept pace with the output, and shows little elasticity in spite of a greatly increased demand. The slow development of the recently-opened mines is also largely due to deficient labor.

Seasoning and Treating Telephone Pole Cross-Arms.

There are used every year in the United States about 14,000,000 cross-arms for telephone and telegraph poles. Of these, perhaps one-fourth are now treated with preservatives to increase their durability, and there are at least five plants, at New York city, Norfolk, Va., New Orleans and Slidell, La., and West Pascagoula, Miss., at which cross-arms are treated. Because of their small size as compared with the strength required and the weakening effect of the holes for insulator pins, and their constant exposure to all kinds of weather, cross-arms should receive a thorough treatment. A good treatment with creosote will at least treble their durability.

A large portion of the supply of cross-arms comes from the South; they are sawed from the loblolly or old field pine, of which there is a large quantity throughout this region. This tree grows rapidly, but contains much sapwood which is difficult to season. It has been said that "loblolly pine sapwood will rot before it will season in the warm, damp climate of the South." While this is probably overdrawn, it is necessary so to pile the cross-arms that the air may circulate freely about them, and to protect them from rain and snow by a roof of loose boards.

Sapwood absorbs preservatives so much more readily than heartwood that when both cross-arms in which sapwood abounds and those in which heartwood predominates are treated in the same run the former absorb an excessive amount before the latter have received what they require. This is not only a needless expense but a detriment, inasmuch as the excess of creosote in the sapwood later oozes out and drips on those who walk beneath. To solve this difficulty, the cross-arms should be sorted in three classes, as sapwood, intermediate and heartwood, and treated in different runs.

Cross-arms are treated in large, horizontal cylinders varying from ninety to 180 feet in length and from six to seven feet in diameter. Into these the arms are run on skeleton trucks, and the doors are then bolted air-tight. Creosote is next run until the remaining space in the cylinder is filled. Pressure is sometimes then applied by pumps to force the preservative into the wood. In some instances before the preservative treatment, the cross-arms are treated to a bath of living steam, followed by the drawing of a vacuum, to remove moisture and secure rapid penetration of the wood by the preservative.—*From Circular 151 on "Creosoting Loblolly Pine Cross-arms," issued by the United States Forest Service, Washington, D. C.*

Electro-Acoustic Method of Measuring Distances at Sea.

Debrix has invented an ingenious method of measuring the distance of a vessel which cannot be seen, because of darkness, fog, or intervening objects. The method is based on the difference between the velocities of sound and Hertzian waves.

At the receiving station, which we may suppose to be a lighthouse or semaphore station on the coast, a train of clockwork causes a pointer to move over a divided dial at the rate of one division per second. The clockwork is started by a Hertzian wave, which is sent out by the ship simultaneously with a sound wave, produced by a gun, siren, or whistle. As the propagation of Hertzian waves is practically instantaneous, the pointer may be regarded as starting at the instant at which the sound wave leaves the ship. The observer on shore watches the pointer and notes its position at the moment the sound reaches his ears. The distance of the ship is then obtained by multiplying the number of divisions traversed by the pointer by the velocity of sound (about 1,100 feet per second).

The position of the ship can be determined with greater precision, says the *Scientific American*, if the Hertzian and auditory signals are received by two shore stations, which can communicate with each other by telegraph or telephone. The distance of the ship from each station having been found, the ship's position on the chart will be at the intersection of two circular arcs drawn about the stations, as centers, with radii equal to the two distances. The result might then be telegraphed to the ship.

A still better plan would be for each of the chain of coast stations to emit, at regular intervals, simultaneous Hertzian and auditory signals (the stations being distinguished by peculiarities in the signals, as lighthouses are now differentiated). Then any ship provided with the simple receiving apparatus described above could determine its position at any time and make its way safely to port.

Ampere Tablet Unveiled.

A bronze and tile memorial tablet in honor of the French scientist, Andre-Marie Ampere, has been set up in the Lackawanna railroad station at Ampere, N. J., by Dr. Schuyler Skaats Wheeler.

The ceremonies were opened by the acceptance by Vice-President Caldwell, of the Lackawanna Railroad, of the tablet, which His Excellency, the French Ambassador, was requested to unveil.

Dr. Wheeler said that the assemblage had gathered in order to honor the name of Andre Marie Ampere, one of the great founders of electrical science, who was born at Lyons in 1775, and died at Marseilles in 1836. His name has been given to the unit of electrical current, and in every civilized country in the world the word "ampere" is used as much as "pound," "second," or "inch." The present site of the unveiling was named Ampere twelve years ago, but until the Lackawanna Railroad completed the new station there was no appropriate place for such a tablet.

DR. SCHUYLER SKAATS WHEELER, DONOR OF THE AMPERE TABLET.

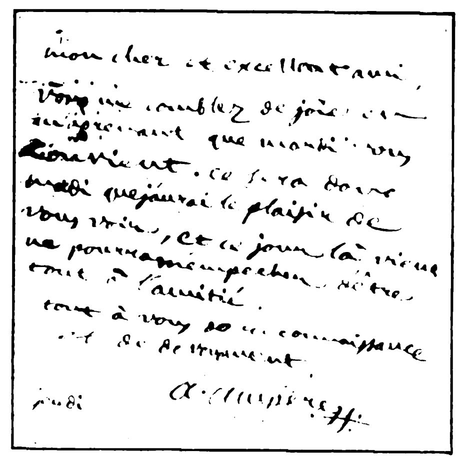
His Excellency said that nothing was more touching for a man from France, and especially for the representative of France, when traveling in America, than to notice so many places bearing French names, recalling ancient French history. There are so many towns and cities recalling the names of Joliet, Marquette and La Salle, and all those early pioneers who settled in the valley of the Mississippi and the north of this great country, and also the famous series of names, Lafayette, Rochambeau and La Luzerne, which are written on the map and also in the hearts of the people. It must not be believed that America is allowed to honor French names without French reciprocation. In France American names confront one at every step. In Paris will be found a boulevard named after Franklin, a street named after Washington, and one named after Lincoln. These names tell of an ancient blessed and solid friendship.

THE AMPERE TABLET, UNVEILED BY HIS EXCELLENCY, THE FRENCH AMBASSADOR, AT AMPERE, N. J., DECEMBER 3.

His Excellency is a native of the same town—Lyons—as Ampere. This is one of the oldest cities in France and one of the most peculiar. It is a Roman town, and for a long time was one of the foremost in France, being the first to receive Christianity, and during the Renaissance was at the head of the towns receiving the new learning. Ampere belonged to one of the austere French families. His father was a justice of the peace, and during the revolution followed the dictates of his conscience, and suffered for it. A few hours before his death he wrote in a firm, steady hand his farewell to his wife. He said: "I have in my heart as a consolation the knowledge that I did my duty without fail. I leave you poor, but you will remember that it was through no squandering of mine; no lack of care. The only expense into which I went with some extravagance was for the purchase of mathematical and geometrical books for our little son. There is nothing that I do not expect of him." That little son was the great man who was thus being honored. Ampere's name will survive in books, but, owing to Dr. Wheeler, it will also survive in another way; it will survive on the map of the United States, and the name of Ampere will last forever. His Excellency closed by saying: "As a Frenchman and compatriot I wish prosperity and happiness to Ampere."

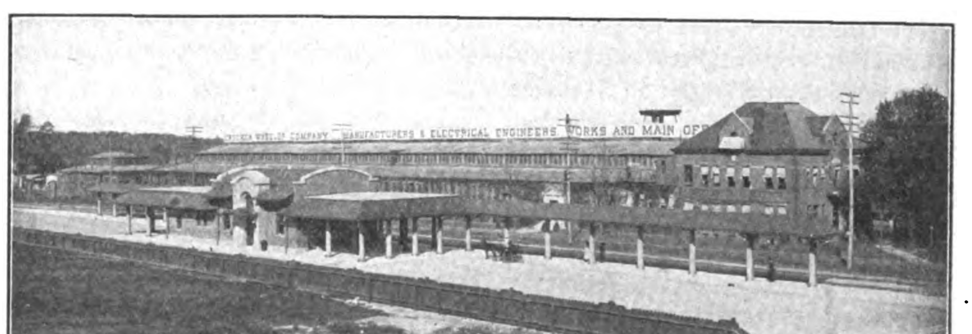
Production of Platinum in the United States.

The decline in price of ingot platinum on the New York market from $38 per troy ounce on January 1, 1907, to $25 per ounce on December 31 of the same year, was accompanied by a notable decrease in production of fine platinum—from 1,439 ounces, valued at $45,189 in 1906, to 357 ounces, valued at $10,589, in 1907. Of the total output in the later year 300 ounces came from Butte, Del Norte, Humboldt, Placer, Plumas, Trinity and Sacramento counties, in California, and fifty-seven ounces from Coos, Curry and Josephine counties, in Oregon.



Mon cher et excellent ami,
Vous me comblez de joie en m'apprenant que mardi vous reviendrez. Ce sera donc mardi que j'aurai le plaisir de vous voir, et ce jour là rien ne pourra m'empêcher d'être tout à l'amitié.
Tout à vous de reconnaissance et de dévouement.
A. Ampère

AN AMPERE AUTOGRAPH LETTER.



BIRD'S-EYE VIEW OF THE CROCKER-WHEELER COMPANY'S WORKS AT AMPERE, N. J.

THE NEW YORK MEETING OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

ANNUAL MEETING, DECEMBER 1-5. PAPERS AND DISCUSSION.

The subjects attracting the greatest attention at the annual meeting of the American Society of Mechanical Engineers, held December 1-4, in the Engineering Societies Building, New York, were the conservation of national resources, machine-shop practice, aeronautics and the training of workmen. But one paper was presented on this latter subject. The ensuing discussion, however, was most enthusiastic and of a most illuminating character.

The convention was opened on Tuesday evening, with President M. L. Holman's address on the conservation of our national resources. Mr. Holman was present at the recent conference called by President Roosevelt, as the representative of one of the four great engineering societies. In his address he reviewed briefly the work of this conference and the scope of the movement. He touched on the importance of the health and life of the people as a national resource, and the work that is being done along this line. The conserving of the timber supply is another subject of considerable importance. The work of the irrigation engineer enters here as making arid lands available for timbering, and the timbering of land conversely reacts favorably on the fertility of the country. Closely allied to irrigation problems are those of waterpower, although this latter cannot be properly called a problem of conservation. It is merely one of development; the water is there, and its use or non-use for power development does not decrease or increase the available supply. The only real interest in this subject from the conservation standpoint is the preserving to the public good the water rights of available power possibilities. The address went deeply into the subject of mineral resources, chief among which are fuel and iron ore. Improved methods of mining are necessary, both to avoid waste of the material mined and to decrease the awful loss of human life, which is far worse in America than in foreign countries. An interesting point brought out in connection with the conservation of iron ore was that eventually only enough ore would have to be mined to replace the losses of wear and tear. There are thousands of tons of iron in scrap piles which are not utilized because it does not pay to rework it. As the available supply of ore diminishes the scrap dealer will be a much more important factor than he now is.

Following the presidential address, Dr. John A. Brashear was presented to the society for honorary membership, which was conferred on him by President Holman. Dr. Brashear then delivered a most brilliant lecture on stellar photography, in which he traced the formation of planets, etc., illustrating his talk with some remarkable photographs of nebulæ and other celestial objects. He also outlined the method of calculating siderial distances and other computations in the field of astronomy.

The Wednesday morning session was partially given up to a paper on the relation of the engineer to the people, by Morris L. Cooke, who thought that many present-day conditions, among them the broadening of human knowledge, and the generally recognized necessity for co-operation, will force the engineering profession and the individual engineer to take a more direct interest in affairs affecting the public. If engineering is to take full possession of the field which the public is willing it should occupy, more effort must be made to enlighten the public as to the objects and achievements of engineering, more effort must be put forth along lines of purely public interest, and every opportunity given the public to cooperate with the engineer. The discussion on this paper emphasized the necessity of acquainting the public more fully with its vital relationship to the engineering profession, and the necessity of having legislation which involves questions of engineering guided by the national engineering societies. It was shown how proper co-operation between the public and other professions, such as medicine and architecture, had served to bring about an increasing appreciation of their value to the public.

The principal feature of this session was a comprehensive paper by Major George O. Squier, of the Signal Corps of the United States Army, which dealt with the present status of miltary aeronautics. This paper outlined quite completely the types of successful military balloons in the United States and foreign countries, detailing the construction of the dirigible French types, of Count Zeppelin, and of the United States and England. It also took up the problems of design of these types, and then discussed aeroplanes in much the same fashion. The work of Herring, Farman, the Wright brothers and others was explained, and the action of airshps was compared to that of vessels navigating the water. The application of airships to warfare was considered, and it was shown, and the manner in which they would work for peace and delimit frontiers was brought out.

In connection with this subject, Lieut. Frank P. Lahm, also of the Signal Corps, gave a stereopticon lecture on Wednesday evening, which was also illustrated with moving pictures, showing in flight the Zepplin dirigible balloon, and the Wright brothers' aeroplane.

The Wednesday afternoon session comprised two papers on fuel-oil burning, by C. R. Weymouth, of San Francisco, Cal., and two others on the total heat of saturated steam and on a method of obtaining ratios of specific heat of vapors. In Mr. Weymouth's first paper are presented results of tests at the 15,000-kilowatt power plant of the Pacific Light and Power Company, Redondo, Cal., having steam-engine prime movers, crude oil being used as fuel. The fuel economy is stated for tests on a 5,000-kilowatt plant unit at various uniform loads, approximating 2,000, 3,000, 4,000 and 5,000 kilowatts; on a variable railway load; and also for the entire station on a similar variable railway load. The operating and test conditions are fully described.

The results given indicate a remarkable plant economy under all conditions, but the particularly striking feature is the almost uniform fuel economy for the plant unit for all fractional loads from about one-half load up to the maximum load tested. The author believes that the results warrant a careful investigation as to the possibilities in the line of superior plant fuel economy, using the more modern types of steam engines as prime movers.

The second paper described the unnecessary losses in firing fuel oil and an automatic system for eliminating them as installed in the Redondo plant.

An oil-pump governor actuated by variations in the boiler steam pressure so varies the oil pressure in a common oil main, and accordingly the simultaneous rate of firing in all burners, as to maintain practically uniform steam pressure at the boilers. This variation of pressure in the oil main is the secondary means for controlling the supply of steam to the burners for purposes of atomization, and also for controlling the amount of damper opening, and thus the air supply for combustion. Due to this automatic and synchronous adjustment of all the functions of the boiler and furnace, there results on plants subject to fluctuating load an increased boiler economy, which is due to the more uniform rate of firing, the saving in steam used for atomizing the oil and the reduction to a minimum of the air supply for combustion.

In the discussion which followed these papers, the speakers almost uniformly took exception to the implied statement that reciprocating engines were largely responsible for the good showing made, and to the statement that as a steam turbine would only show high economy in connection with a good vacuum, the vacuum should be charged back against the turbine. This was considered to be most unfair to the turbine. The speakers all contended that turbines, operating under similar conditions, would show just as high if not higher economy than the engines.

A. R. Dodge's paper on the specific heat of vapors considered a method of obtaining ratios of specific heats which does not involve the use of available steam tables conceded to be too inaccurate for such investigations, nor a condition in which the steam is presumed to be without moisture or superheat. This method is based upon the expansion of initially superheated fluid in a throttling calorimeter, and tables are included showing data for steam.

Harvey N. Davis' paper on the heat of saturated steam stated that Regnault's formula for the total heat of saturated steam, $H = 1091.7 + 0.305 (t - 32)$ British thermal units, is considerably in error. This conclusion is confirmed by computing H above 212 degrees, in terms of H_{212}, from the throttling experiments of Grindley, Griessmann and Peake, and the direct specific-heat determinations of Knoblauch and Jakob. The result is: $H = H_{212} + 0.3745 (t - 212) - 0.000550 (t - 212)^2$. The best value of H_{212} seems to be 1150.3 British thermal units. The range of the new formula is from 212 degrees to about 400 degrees. The greatest error in Regnault's formula in this range is six British thermal units at 275 degrees, but if extrapolated to higher temperatures the error in it increases very rapidly. Below 212 degrees the observations of Dieterici, Smith, Griffiths, Henning and Joly show a thoroughly satisfactory agreement among themselves, and prove that Regnault's formula runs high, the error reaching eighteen British thermal units at thirty-two degrees. There are corresponding errors on the specific volume values ordinarily used.

Most of the speakers discussing these two papers did so by means of complicated formulæ on the blackboard, which it was impossible for the audience to follow.

The papers presented on Thursday morning were almost wholly devoted to machine-shop practice. A. L. De Leeuw read one on efficiency tests of milling machines, which points out the desirability of indicating the power of a machine tool by the amount of metal which it is capable of removing. It shows the results of tests made for finding the net horsepower required to remove a given amount of metal under given conditions. Other tests were made to determine the efficiency of the feed and driving mechanism. In this connection an electrical method was used, comprising two machines, rigidly connected at their spindles, one being driven by a motor, and the other driving a generator. The power input was determined, from the electrical readings, the efficiency curve of the motor being known, and the output of the generator was also measured. From the difference in power of the two electrical machines the efficiency of the milling machines was easily determined. The discussion on this paper, and on the one which followed, describing a new high-speed milling cutter, dealt mostly with questions of the proper shape of metal cutting tools, and incidentally touched on the revolution in machine-shop practice brought about by the motor drive.

A paper on interchangeable involute gear-tooth systems, by Ralph E. Flanders, gave diagrams showing the effect of varying the pressure angle and addendum on the various practical qualities of gearing, such as interference, number of teeth in continuous action, side pressure on bearings, strength, efficiency, durability, smoothness of action, permanency of form, etc. After comparing typical examples of interchangeable gear systems in these particulars, the author concludes that a new standard for heavy, slow-speed gearing is advisable.

The paper provoked a rather aimless discussion which showed mainly that there were yet many things to be learned about gearing. The discussion was so protracted that it had to be continued at an afternoon session, at which Norman Litchfield's paper on spur gearing in heavy railway-motor equipments was read and which dealt with the breakage of gearing in heavy electric-railway service, as typified by the equipments of the Interborough Rapid Transit Company, New York, which operates the elevated and subway lines. A resumé is given of the methods employed to overcome the breakage, and the strains in the teeth as calculated by the Lewis formula are shown. Attention is called to the fact that this formula is not entirely applicable on account of the difficulty in maintaining alignment of gear and pinion.

The paper attracting the most attention at the regular Thursday afternoon session was Henry L. Gantt's on training workmen in habits of industry. In this paper Mr. Gantt says that until within a few years the mechanic was necessarily the source and conserver of industrial knowledge, and on him rested, therefore, the responsibility for training workmen. With the advent of the scientifically-educated engineer capable of substituting a scientific solution of problems for the empirical solution of the mechanic, the responsibility of training workers naturally shifts to his shoulders. If he accepts this responsibility, and bases the training on the results of scientific investigation, the efficiency of the workman can be so greatly increased that the manufacturer can afford to give those that take advantage of this training compensation in excess of that usually paid for similar work.

Many speakers warmly praised Mr. Gantt, who was associated for many years with F. W. Taylor while the latter was developing his system of shop management. It was brought out that men trained under Mr. Gantt's principles made better workmen, better managers, received higher pay and were more contented than the average man. The speakers especially commended the helpful and humanitarian tone of Mr. Gantt's paper, in which it was shown that the operation of the principles therein enunciated was to the benefit of employer and workman alike. The testimony of all who had used the systems developed by Mr. Gantt and Mr. Taylor was to the effect that the results were far beyond their most sanguine hopes.

A liquid tachometer was described at this session by Amasa Trowbridge, of great accuracy and simple construction.

A paper of considerable interest was that of C. J. Mellin on articulated compound locomotives, which was discussed by S. M. Vauclain by means of lantern slides which traced the development of the Mallet locomotive.

Another paper of considerable interest, also accompanied by lantern slides, was that of S. Ashton Hand, on industrial photography. Mr. Hand outlined the steps necessary to attain success in photographing machinery, and gave a resumé of the methods used by him to correct errors of focusing, exposure, developing and printing. The paper was most interesting and was well received.

At the meeting of the Gas Power Section, held Thursday afternoon, L. H. Nash gave some reminiscences of gas-engine design, which formed a brief outline of certain features that have been tested from time to time, many of which have taken their places in the development of the gas-engine art, some being abandoned after trial for commercial use. The intention of the article is to stimulate thought along the lines referred to. Among other things, is a brief mention of a method of operation for marine purposes, many of the chief features of which are in more or less active service today, although there are others which seem to possess value enough to warrant their being brought to the attention of the engineering profession.

Another paper presented at this session was entitled "Possibilities of the Gasoline Turbine." This was by Prof. Frank C. Wagner. In order to reduce the temperature of the gases at the turbine wheel, either an excess of air or water injection may be used. The relative efficiencies of the two methods was shown to depend upon the amount of compression used, and the efficiencies of the turbine and the air compressor. The work required to compress the air may be materially reduced by using two-stage or three-stage compressors with intercoolers. It appears that with high compression the gasoline turbine may be expected to give efficiencies comparing favorably with the reciprocating gasoline engine.

The papers read at the Friday morning session attracted but little attention, due mainly to the many excursions arranged for this time, which cut into the attendance on the professional session. The papers were on the slipping points of rolled boiler-tube joints, on the storage and transmission of carbonic acid and on an averaging instrument for polar diagrams. There was almost no discussion, and the meeting adjourned at an early hour. During the meeting it was announced that Jesse M. Smith, of New York, had been elected president, and that 191 new members had been elected. Preliminary steps for the formation of a section on the machine shop were also taken.

The entertainments and excursions provided for the meeting were on an elaborate scale. In addition to the two illustrated lectures noted above, and the regular reception, there were excursions to various power stations around New York, to the Pennsylvania tunnels and terminals, to the Queensboro bridge, to the high-pressure fire-service stations, and to many manufacturing plants.

Hudson River and Pennsylvania Telephone Companies Absorbed by the Bell.

Stockholders of the Hudson River Telephone Company and the New York & Pennsylvania Telephone and Telegraph Company have been advised by Francis G. Wood, secretary of the companies, that their stock holdings will be exchanged for stock in the Bell Telephone Company of Pennsylvania. The exchange will be made on the basis of one share of Bell Telephone Company of Pennsylvania stock for two shares of New York & Pennsylvania Telephone Company stock. In the case of the other company, the offer is on the basis of one share of Bell Telephone Company of Pennsylvania for one-and-one-half shares of Hudson River Telephone Company.

The outstanding capital stock of the Hudson River Telephone Company is $3,909,900, of which $2,033,100 is owned by the American Telephone and Telegraph Company. The latter company also owns half of the $1,000,000 capital stock of the New York & Pennsylvania Telephone and Telegraph Company.

The Bell Telephone Company of Pennsylvania operates throughout a large part of Pennsylvania, New Jersey, and Maryland, and in a portion of Delaware and the District of Columbia. It embraces such cities as Philadelphia, Harrisburg, Allentown, Wilkesbarre, Lebanon, Williamsport, Camden, Wilmington, and other points, and further south it includes Baltimore and Washington.

The gross earnings of the Bell Telephone Company of Pennsylvania, in 1907, were $7,670,439; net earnings were $2,410,953. This was an increase of $925,931 in gross over 1906, and $456,835 in net earnings.

The Bell Telephone Company of Pennsylvania has paid a dividend of six per cent for a number of years. The Hudson River Telephone Company has paid no dividends since the latter part of 1907, when it paid four per cent. The New York & Pennsylvania Company has paid no dividends since 1900.

Steam Railroads Must Exchange Carload Freight with Indiana Electric Lines.

The Indiana Railroad Commission has rendered a decision making it incumbent upon a steam road to enter into an interchange of carload traffic with an interurban road, regardless of whether two or more steam roads have entered into an agreement not to exchange their car traffic. The decision followed litigation between the Winona Interurban Railway Company and the Big Four Railroad, wherein the former sought to compel the latter to deliver any cars to the interurban railway at Warsaw. The Commission holds that interchange of traffic such as is involved in this case, and where there is a physical connection between the steam and interurban line, would enlarge the opportunities of the shipping public, and would also bring steam and interurban roads into rightful competition.

The contention of the officials of the steam line that the interchange of traffic in carload lots with interurban roads would bring their equipment under the control of the interurbans and their rolling stock into use for interurban business, the Commission holds is not well taken since the Commission can and will prevent any such abuse of equipment by the interurban companies. The decision is regarded of great importance, and it remains to be seen if the steam road will make any further resistance to the order of the Commission. S.

Pennsylvania Trolley and Light Merger.

The United Gas and Electric Light Company and the Irondale Electric Light Company, of Bloomsburg; the Standard Gas Company, of Danville; the Berwick Electric Light Company, of Berwick, and the Columbia & Montour and the Danville & Bloomsburg Electric Railway companies, all in Pennsylvania, have been merged into one corporation.

The electric power houses in some of the towns mentioned will eventually be dispensed with, it being the purpose to secure some of the power necessary for operating the trolley roads from Harwood, near Hazleton, where a mammoth plant, which uses the culm from nearby banks for fuel, has been erected.

The personnel of the new company is not announced. The deal was consummated by E. R. Sponsler, of Harrisburg, and A. W. Duy, of Bloomsburg, who have been working on it for several months.

It is understood that a number of improvements will be made.

FINANCIAL REPORTS OF ELECTRICAL COMPANIES.

ONEIDA RAILWAY COMPANY.

The report of the Oneida Railway Company for year ending June 30 shows as follows: Gross operating revenue, $288,972; operating expenses, $184,448; net operating revenue, $104,524; taxes accrued, $5,830; operating income, $98,694; other income, $1,279; gross corporate income, $99,974; fixed charges, $3,910; net corporate income, $96,064; cash on hand, $23,657; profit and loss, surplus, $91,095.

MASSACHUSETTS ELECTRIC.

The Massachusetts Electric Companies has issued its ninth annual report, covering the year ended September 30, 1908. The consolidated income account shows as follows: Gross, $7,809,010; expenses, $5,001,517; net, $2,807,492; charges, $1,784,437; balance, $1,023,054; dividends, $880,773; surplus, $142,281, as against $174,462 for the previous year. The profit and loss statement of the parent company compares as follows: Dividends on stock owned, $880,841; miscellaneous interest on notes, $107,961; total income, $988,802; total expenses, $19,395; net income, $969,407; interest on notes, $157,500; surplus, $811,907; total surplus, $2,378,791, which compares with $1,566,884 for the preceding year.

The number of passengers carried by the Boston & Northern and Old Colony street railways, constituent companies of the Massachusetts Electric Companies, during the fiscal year ended September 30, 1908, was 149,649,383, against 148,554,127 in the 1907 fiscal year, an increase of 1,095,256, or three-fourths of one per cent. The 1907 increase over 1906 was 5,990,991, or 4.2 per cent.

The annual meeting of the Massachusetts Electric Companies will be held at Tremont Temple, Boston, December 16, at noon. Shareholders will be asked to authorize the trustees to sell the six per cent preferred stock of the subsidiary companies, which the railroad commissioners recently authorized.

NORFOLK & PORTSMOUTH TRACTION.

The report of the Norfolk & Portsmouth Traction Company for the month of October and ten months ended October 31 shows as follows: October—gross, $156,795; expenses, $88,316; October—net, $68,479, as against $98,561 for October, 1907. Ten months' gross, $1,552,029; expenses, $923,587; ten months' net, $628,442, as compared with $875,190 for 1907.

SYRACUSE RAPID TRANSIT.

The Syracuse Rapid Transit Railway report, as filed at Albany, for the year ended June 30, 1908, is as follows: Gross, $1,292,886; expenses, $822,197; net, $470,689; other income, $19,405; total income, $490,094; charges, $334,606; surplus, $155,488; dividends, $70,188; year's surplus, $85,300, which compares with $127,808 for the preceding year. Cash on hand, June 30, $85,300; profit and loss surplus, $439,931.

UNITED TRACTION OF ALBANY.

The United Traction Company's report, as filed at Albany, for the quarter ended September 30, 1908, is as follows: Gross, $520,679; expenses, $302,187; net, $218,492; other income, $40,014; total income, $258,506; charges, $98,877; surplus, $159,629, as against $174,854 for the preceding year.

HUDSON VALLEY RAILWAY COMPANY.

The Hudson Valley Railway Company's report, as filed at Albany, for the quarter ended September 30, 1908, shows as follows: Gross, $196,474; expenses, $135,558; net, $60,916; charges, $56,661; surplus, $4,255, a decrease of $34,418, as compared with the corresponding quarter of 1907.

NORTH SHORE ELECTRIC.

For the fiscal year ended September 30, 1908, the North Shore Electric Company, which supplies electrical energy in the suburbs about Chicago, reports gross earnings of $815,551; expenses (including taxes and rentals), $533,619; net earnings, $281,932; interest on bonds, $159,283; special depreciation reserve, $64,100; dividends, $42,702; balance, $15,847; total surplus, $119,970. The plants, real estate, franchises, etc., were valued at $7,110,924 and the total assets at $8,096,745. The outstanding capital stock was $3,780,000; bonds amounted to $3,715,000. The profits for the year were equal to substantially three-and-one-half per cent on the capital stock.

LONDON UNDERGROUND.

The Underground Electric Railways of London report earnings for each division of the system for the week and twenty weeks ended November 14 as follows: Baker Street and Waterloo, £3,145; Piccadilly, £5,445; Hampstead, £3,530; District, £10,106; Tramways, £5,192; total, £27,418, an increase of £2,354 over the same week of 1907. Total twenty weeks to date, £560,511, compared with £484,362 for the preceding year, an increase of £76,449.

DETROIT UNITED.

The report of the Detroit United Railway Company (all properties) for the month of October and ten months ended October 31 is as follows: October gross, $613,127; expenses and taxes, $412,650; October net, $200,477; other income, $6,363; total income, $206,840; charges, $133,379; October surplus, $73,461, which compares with $66,122 for October, 1907. Ten months' gross, $5,937,982; expenses and taxes, $3,807,903; ten months' net, $2,130,079; other income, $51,420; total income, $2,181,499; charges, $1,352,239; ten months' surplus, $829,259, as against $954,363 for the corresponding months of 1907.

ROCHESTER & EASTERN RAPID.

Rochester & Eastern Rapid Railway's report, as filed at Albany, for the year ended June 30, 1908, is as follows: Gross, $279,816; expenses, $221,520; net, $58,296; other income, $207; total income, $58,503; charges, $106,214; deficit, $47,711, which compares with a deficit of $30,095 for 1907.

MONTREAL STREET RAILWAY.

The report of the Montreal Street Railway Company for the month of October is as follows: October gross, $328,608; expenses, $168,124; October net, $160,484; charges, rentals, etc., $27,480; October surplus, $133,003, as compared with $119,455 for the corresponding month of 1907.

TOLEDO RAILWAYS AND LIGHT.

The report of the Toledo Railways and Light Company for the month of October and ten months ended October 31 is as follows: October—Gross earnings, $218,074; operating expenses, $119,982; net earnings, $98,092; other income, $187; total income, $98,279; charges and taxes, $71,953; surplus, $26,326, as against $30,138 for October, 1907. January 1 to October 31—Gross earnings, $2,082,897; operating expenses, $1,139,806; net earnings, $943,091; other income, $3,260; total income, $946,351; charges and taxes, $707,696; surplus, $238,655, a decrease of $11,786 from the surplus for the corresponding period of 1907.

ALTERNATING CURRENTS AND THEIR APPLICATIONS.

BY EDSON R. WOLCOTT.

CHAPTER II. (PART I).—GENERATORS.

TYPES OF ALTERNATING-CURRENT GENERATORS.

In order to generate an electric current there must be relative motion between a conductor and a magnetic field. So far as the production of the current is concerned, it is immaterial whether it is the conductor or the magnetic field that is in motion.

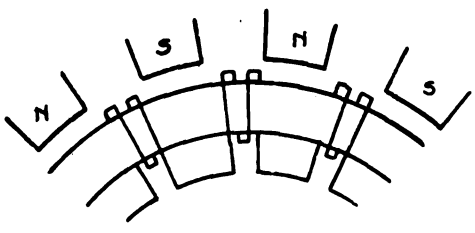


FIG. 38.—RING-WOUND ARMATURE.

In an alternating-current generator in which the conductor rotates and the magnetic field is stationary we have what is known as the rotating-armature type of alternator. It is similar to the direct-current generator in arrangement of analogous parts.

When the magnetic poles are rotated past a stationary armature in which the electromotive force is induced, the machine is called a rotating-field alternator.

In the inductor type of alternator both armature and field parts remain stationary, while the rotation of a magnetically-conducting element past the parts effects an alternating shunting of the field flux through the armature coils, securing the relative motion defined as necessary to electromagnetic induction.

THE ELECTROMOTIVE FORCE OF AN ALTERNATOR.

The electromotive force generated by an alternator as read by a voltmeter at the terminals is as follows:

$$\text{Terminal voltage} = \frac{2\pi f \phi N}{\sqrt{2}\, 10^8} = \frac{4.44 f \phi N}{10^8}$$

where N represents the number of turns of wire in series enclosing the magnetic flux, ϕ the number of lines of force from each pole passing through the winding in which the electromotive force is generated, and f the cycles per second, which equals the number of revolutions per second multiplied by one-half the number of poles. The voltage is thus proportional to the strength of the magnetic field, the number of conductors in the armature, the number of poles and the speed.

ROTATING-ARMATURE GENERATOR.

The rotating-armature generator is a type that has played a very important part in the development of alternating currents, although it is now being displaced by machines in which the field coils rotate.

The armatures of this class of machines have been wound in various ways. At first the armatures were in the shape of discs. Later they took the form of iron rings wound with insulated conductors, as shown in Fig. 38. The type generally in use in this country, however, is the so-called drum armature, illustrated in Fig. 39. It is similar in appearance to that used in a direct-current generator, although the simple alternator has no commutator, being provided with only collecting rings. In some machines, however, there is a commutator for rectifying part of the current for exciting the fields. The armature windings are embedded in slots in the laminated iron core. The more iron around the conductors and the less air-gap between them and the magnetic poles, the greater will be the magnetic flux. The iron is laminated transversely to the axis to decrease the eddy-current losses.

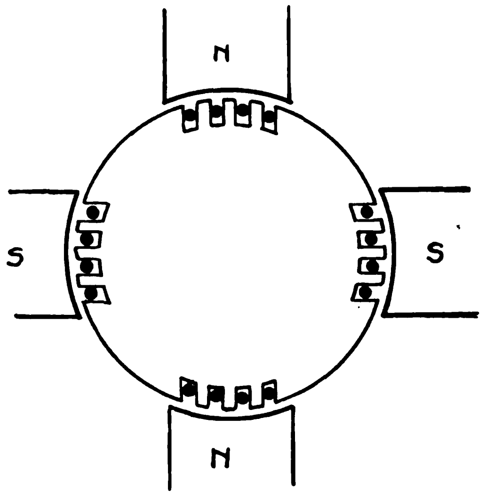

FIG 39.—DRUM-WOUND ARMATURE.

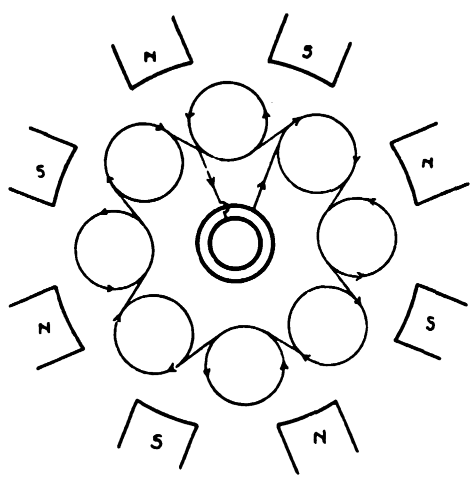

FIG. 41.—METHOD OF CONNECTING ARMATURE COILS OF AN EIGHT-POLE ALTERNATOR.

A six-pole generator of this type is illustrated in Fig. 40. The six pole windings are arranged symmetrically within the iron frame. The armature windings are in six corresponding coils, all connected in series; the terminals are connected to the collecting rings in the center, as shown. The magnetic lines of force pass from an N pole across the short air-gap into the iron core within the surrounding coil of insulated conductor, and then divide, part of the flux passing in one direction through the iron and up through the coil opposite one of the adjacent S poles, and part to the S pole on the other side.

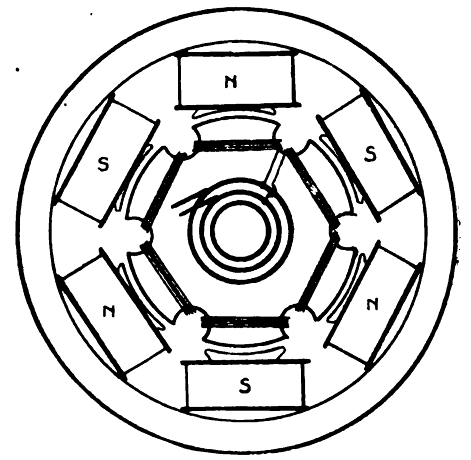

FIG. 40.—SIX-POLE, SINGLE-PHASE ALTERNATOR.

METHOD OF CONNECTING COILS.

The method of connecting the coils is shown more clearly in Fig. 41. Consider the loops as filled with iron, the coil being wound within the slots opposite the pole pieces. Adjacent coils are wound in opposite directions, as the adjacent poles are of opposite polarity. They are all connected in series, as shown, and the terminals are connected to the collecting rings in the center. The current is taken from these by means of brushes (not shown).

EXCITING CURRENT.

A direct current in the field coils is necessary to produce the magnetic flux. This is usually obtained by means of a small direct-current generator. The alternator is then said to be separately excited.

MAGNETIC SATURATION.

When an alternator is driven at constant speed and no load, no current being drawn from its armature, its electromotive force increases, approximately as the current through the field coils increases, up to a certain point, as shown in Fig. 42. At the maximum the iron is said to be saturated with magnetism, since any further increase of the field current is

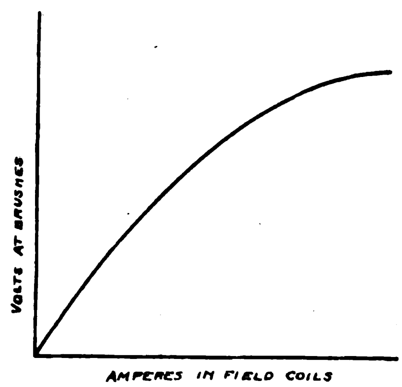

FIG. 42.—MAGNETIC SATURATION OF ALTERNATOR FIELD.

without effect on the electromotive force generated.

When iron is magnetized it may be considered that some of its component particles swing into line just like so many compass needles near a magnet.

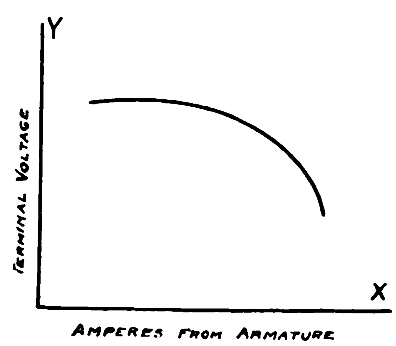

FIG. 43.—DROP OF ALTERNATOR ELECTROMOTIVE FORCE WITH INCREASE OF LOAD.

The more the iron is magnetized the greater the number of particles are to be thought of as lined up in the same direction, until finally, when they are all in line, the magnetic "saturation point" is reached.

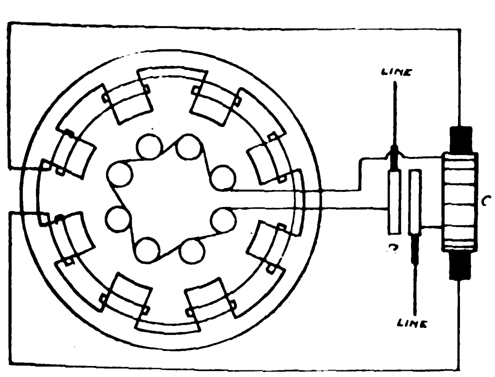

FIG. 44.—SERIES-WOUND ALTERNATOR.

RELATION BETWEEN TERMINAL VOLTAGE AND LOAD.

As the load on an alternator changes, the field excitation remaining constant, the electromotive force drops, as shown in Fig. 43. The voltage at the terminal of the generator is plotted along the axis OY, and the current drawn from the armature is plotted along the axis OX. As the load increases, the voltage decreases. Increasing the current through the field coils will again increase the electromotive force generated. This can be done by hand regulation of a rheostat placed either in the external circuit of the direct-current exciter or in the field circuit of the exciter in case the latter is a shunt-wound machine.

SERIES-WOUND ALTERNATOR.

When all of the current is rectified and passed through the field coils, the gener-

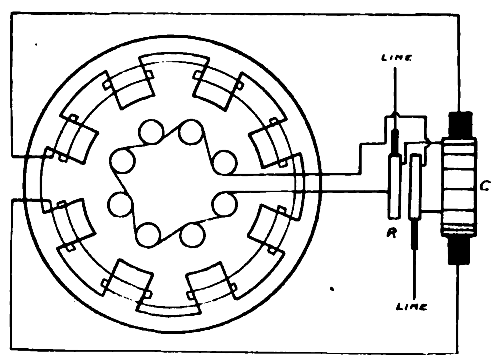

FIG. 45.—SHUNT-WOUND ALTERNATOR.

ator is series wound and is much like the series-wound direct-current machine. The method of connection is illustrated in Fig. 44. The armature windings are represented by the inner coils; one of the ter-

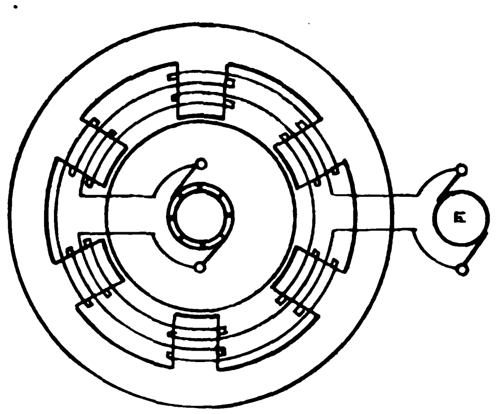

FIG. 46.—COMPOSITE EXCITATION OF ALTERNATOR.

minals is connected to one of the collecting rings R and the other to the commutator C, which is again connected to the other collecting ring. The current is thus unidirectional only while passing through the field coils.

SHUNT-WOUND ALTERNATOR.

In the shunt-wound type the commutator difficulties are not so great, for only a part of the current passes through the field coils, as shown in Fig. 45. The armature is connected directly to the collecting rings, and the field coils are connected in parallel through the commutator.

SEPARATELY-EXCITED ALTERNATOR.

A very common method of excitation is by means of a direct current from a storage battery or a small direct-current generator belted or direct-connected to the alternator, or to the prime mover. The current through the fields is usually controlled by hand regulation by means of a rheostat in the alternator field circuit or in the shunt winding of the exciter. This is known as a separate excitation.

COMPOSITE EXCITATION.

In some cases there are two separate windings in the field coils, one for self-excitation, the other for separate excitation, as shown in Fig. 46. The regulation of the alternator is then partly automatic, but subject at the same time to hand regulation, thus making a very practical combination.

[*To be continued.*]

Electrician's Helper—United States Civil Service.

The United States Civil Service Commission announces an examination on January 13, at the usual places, to secure eligibles to fill a vacancy in the position of electrician's helper, $50 a month, in the office of the Secretary, Department of Agriculture, and other vacancies requiring similar qualifications.

With reference to the above specific vacancy the Department states that the length of time that it will be able to retain the services of an electrician's helper depends on the amount of work that comes into the shop and also the funds available for the employment of a helper, both of which are impossible to determine in advance.

The examination will consist of subjects weighted as indicated:

Letter-writing, over 125 words, 10; practical questions, elementary in character, relating to the wiring of buildings and installation and care of minor electrical apparatus, 45; experience as electrician's helper, 45.

Applicants whose applications show that they have had less than one year's experience as electrician's helper will not be admitted to the examination. Age limit, eighteen years or over on the date of the examination.

Applicants should at once apply either to the United States Civil Service Commission, Washington, D. C., or to the secretary of the board of examiners at any of the usual places, for application Form 1093.

Developments in Electrification of Railway Terminals.

At a regular meeting of the Western Society of Engineers, held on the evening of December 2, H. H. Evans, secretary of the Chicago council committee on local transportation, presented an interesting paper on "Developments in Electrification of Railway Terminals." It was based principally upon the investigation of the subject made by Mr. Evans and other city officials of Chicago relative to the electrification of the Chicago terminals, particularly that of the Illinois Central Railroad, and which resulted in a voluminous report that was recently completed and which was abstracted in the WESTERN ELECTRICIAN of October 31.

Mr. Evans said that electrification of terminals may be brought about for three distinct reasons: 1, to obviate the nuisance to the public in general and to the passengers in particular; 2, to effect a saving in operation, or 3, to increase the capacity of the system. Each of these factors may be involved to a degree, although usually one of them predominates.

The density of traffic is a vital factor in determining the feasibility of any electrification project. A number of these projects have been carried out in cities that have tunnel entrances to the terminals. In such a situation electrification is practically imperative on account of the danger to life from smoke and sulphurous fumes in the tunnels. The damages caused by smoke, cinders and other objectionable features of steam locomotives both to property adjacent to the lines and to the discomfort of passengers are becoming elements that are bringing about electrification in an increasing number of instances.

The advantages of electrification to any railroad, particularly at its terminals, are manifold. Less cleaning and therefore less wear will be required of the passenger coaches. Decidedly longer life will be allowed to viaducts, bridges and other steelwork over or adjacent the tracks. This will be due to the elimination of sulphurous corrosion, which has weakened and greatly shortened the life of such structures; a viaduct in Boston that was recently examined was a forcible illustration of this fact. Less wear and tear will result on the rolling stock because of the uniform tractive power of the electric motor.

A higher working speed and therefore considerably more mileage is possible with electrical equipment because of the much higher acceleration produced. There will be much less dead movement and dead switching, as the electric locomotive does not have to go to the roundhouse after each run. The New York Central has cut down its dead mileage at the New York terminal more than one-half. There will result a much greater economy in coal consumption, about one-half of that of steam being found sufficient. This factor is of much greater importance where the cost of coal is fairly high. This saving in coal has led to the electrification of at least one or possibly two roads near San Francisco.

The electric locomotive is always ready for operation. Its cost of repairs is decidedly less. This has been found to run about three cents per mile against eight to eleven cents with the steam locomotive. This item is still less on electrically-equipped coaches, particularly where the multiple-unit system is used. With the latter system the entire cost of repairs of steam locomotives in suburban service can be saved. No dead weight has to be hauled as in the case of the locomotive tender loaded with coal and water. Greater loads are possible on an electrified system, since these are limited only by the strength of the drawbar. Delays due to bad weather are very much diminished when the electric locomotive is employed. Its efficiency, if anything, is increased in cold weather, whereas that of the steam engine is much reduced.

The higher speed attainable with electrified service results in a much higher car-mileage capacity. The reasons for electrifying suburban service have generally been rather for getting more revenue from it than for saving money in its operation. The higher speed attracts a greatly increased traffic. With stations as near together as they usually are in suburban service the increased acceleration permits of this higher speed. Operation on the multiple-unit system allows much more frequent service, which is another factor in building up the traffic.

One hour is the maximum limit that people going to and from work care to spend in traveling, even to the remotest suburbs. Increased and faster service on the street cars has increased the distance to which people are being daily carried and has resulted in building up the suburban districts. As the city builds up, however, the zone of the congested traffic steadily widens and this element limits the speed of street-car service. To reach the desirable suburbs, therefore, the most satisfactory means of transportation are by elevated or subway lines, both of which are very costly to build, or by means of the steam railroads that pass through the suburbs. Electrification of their lines seems the very best and cheapest way of building up the suburban districts.

While most electrification projects have at first been confined to suburban traffic only, the complete equipment of the road, so as to provide for the through passenger and freight service as well, results in a very much better load factor on the generating station, since freight is generally moved at other than the rush hours.

Real estate required for the large terminals in our great cities is steadily becoming more expensive. In order to provide for the gradually increased traffic enlarged capacity is necessary, and the cheapest way to obtain it is by electrification, as the present facilities can then be made to accommodate an increased number of trains. To even out the load factor a light freight and express traffic may readily be developed to accommodate the large merchants of the city. This may be arranged to deliver parcels to suburban districts frequently and quickly.

Where the cost of real estate is as high as for instance in New York city, the plan of building an office or warehouse structure over the tracks may be resorted to where these are electrically equipped. It has been proposed to build eighteen or twenty-story warehouses over such an electric terminal. The New York Central makes use of a double-deck terminal, separate levels being provided for the through passenger and suburban trains. This is possible only with electrified service.

At the conclusion of Mr. Evans' address he cited and described at considerable length a great many of the electrification projects that have been so far carried out. He described the New York Central, the New Haven, the Long Island and the Pennsylvania projects in and near New York city, the Baltimore and Ohio tunnel, the North Shore and Southern Pacific lines near San Francisco, the electrified roads around London and Paris, electrified Italian roads, and also the recently-planned project for Melbourne, Australia, where 298 miles of track will be electrified ultimately. He concluded with a brief reference to the situation on the Illinois Central Railroad in Chicago.

The discussion of the paper was opened by P. Junkersfeld, who spoke of a number of ways in which the fixed charges of an electrification project can be reduced and how the load factor on the station can be improved. One suggestion in this connection was that the time of leaving for several competing trains be made different instead of having them leave practically at the same hour. The importance of more frequent and better service on suburban lines that is permissible with electrification is very great in increasing the revenue of these roads.

E. N. Lake said the elements of electrification are very simple. The only element of a steam road as now equipped that is affected by electrification is the steam locomotive, which represents an investment of but five per cent of the total railroad property. He cited Mr. Wilgus' figures on depreciation and fixed charges as being forcible arguments in favor of electrified service. He believes that it is a good thing that there has been the competition between the single-phase overhead and the direct-current third-rail systems on practically similar lines, as it has compelled the manufacturers to perfect their equipment to the highest possible standard and therefore to make it as reliable as can be expected.

James Lyman stated that while electric operation has been regarded hitherto by many as experimental, it is no doubt true that it has passed through these stages, as is shown by the large number of lines already successfully in operation. The standardization of electrical equipment is being achieved to a high degree, as is shown on the various elevated railroads in New York, Chicago, Boston, etc., and on the New York Central and other heavy railroad projects.

It is planned to continue this discussion at the meeting on December 11.

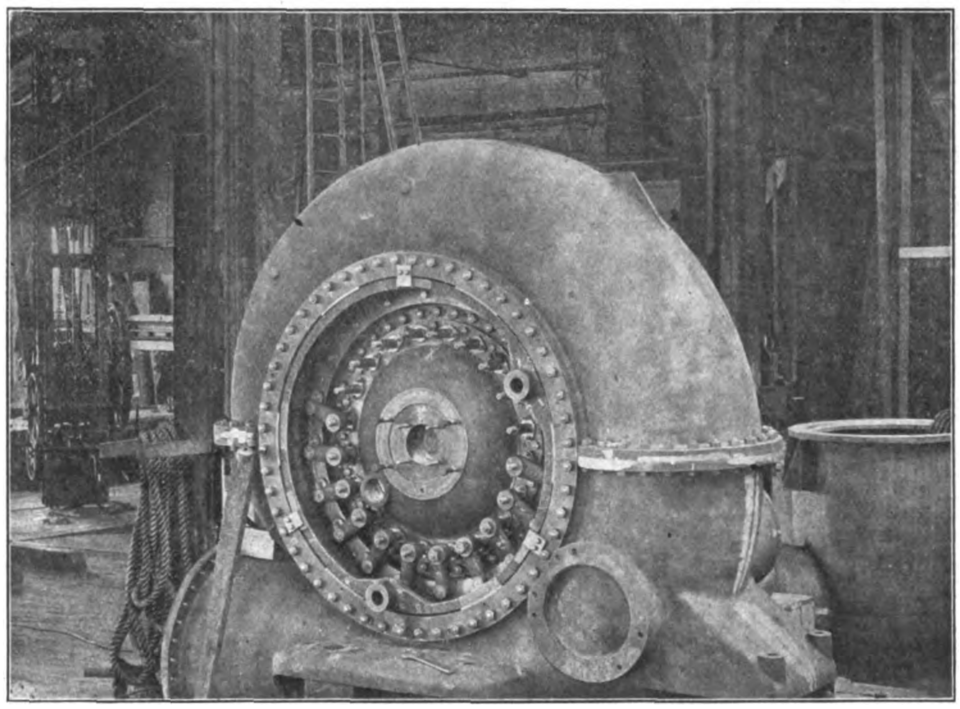
An Electrical Method of Fusing Silica.

The fusing of silica and quartz has been attended with considerable difficulty on account of the high temperature required. A German firm has recently developed an electrical method of fusing silica and molding it into any desired shape. A form of electric furnace is used in which the silica is placed in a carbon tube forming one electrode. This is inserted in a larger tube forming the other electrode and the space between filled with powdered carbon. Current is passed between the carbon tubes and readily causes the fusing of the silica in a perfectly controllable manner. By using an inner core or plug the silica when thoroughly molten can be molded into various shapes.

The Rejuvenation of a Decadent Mining District.

The "bonanza" days of the mining industry are now largely of the past, for men are no longer content to work only the highest "pay dirt" and throw the remainder on the dumps. Now by means of labor-saving machinery and the application of power the mining industry has been reduced to a conservative business proposition which has for its object merely a fair return on the investment actually made.

In order to obtain the best efficiency at least cost it is absolutely essential that cheap power shall be available, whether in coal, oil or waterpower. Without power, working the property is expensive and out of all proportion to the returns.



ALLIS-CHALMERS 5,000-HORSEPOWER HYDRAULIC TURBINE AT THE GUANAJUATO POWER AND ELECTRIC COMPANY'S PLANT, SONORA, MEXICO.

The Guanajuato district of Mexico is an example of what cheap power has done for an otherwise valuable district. What is now one of the most important mining centers in the republic was once hardly a promising proposition. A few years ago the camp was practically dead, most of the large properties having drifted into the hands of a few of the wealthy but inert Mexicans. Two English companies had for years been endeavoring to let go after having made a protracted failure of the attempt to operate in the district, while a few Americans were struggling to save enough bullion out of the low-grade ore to pay the heavy cost of fuel.

Then something happened which transformed the camp into what it is today. It was the advent of a party of Americans with the capital and the courage to build a hydro-electric plant 120 miles away, from which power could be transmitted to the mines.

The hydraulic turbine installed was a 5,000-horsepower Allis-Chalmers single horizontal-type unit in a cast-iron spiral casing with quarter-turn discharge. The waterpower development consists of a diverting dam, a canal five miles long, and two pipe lines, each 3,300 feet long, leading to the waterwheel. There is a cross connection at the power house so that the turbine can be operated from either pipe.

The head under which the turbine operates is 320 feet and the speed is 514 revolutions per minute. The plant was built by the Guanajuato Power and Electric Company, Sonora, Mexico, with Francis O. Blackwell, of New York city, as consulting engineer. The accompanying photo shows the Allis-Chalmers turbine during construction.

Mexican Light and Power.

The English interests in the Mexican Light and Power Company announce they will put through the lease of the company to the Mexico Tramways Company, notwithstanding the fact that the board of directors of the power company has condemned the lease. The English interests now have control of the power stock. The board of directors, which will be forced to resign, includes some of the leading interests in the Bank of Montreal. The English interests are headed by Sperling & Company, of London.

SPUR GEARING ON HEAVY RAILWAY-MOTOR EQUIPMENTS.[1]

BY NORMAN LITCHFIELD.

In the operation of ordinary street-railway motors the gearing is not a serious factor, on account of the low horsepower required, and it is not until the equipment becomes similar in proportions to that of a steam railroad with congested traffic that its importance begins to be felt. With the installation of electric-train service on the Manhattan Elevated Railway in 1901, however, the gearing question forced itself on the attention of the engineers through the large number of failures immediately occurring. On the New York Subway equipments the breakages were still more numerous, for these trains are more powerful than any heretofore used, an eight-car subway express train having motors aggregating 2,000 horsepower, equivalent to a locomotive of about the same power as the new electric locomotives of the New York Central Lines, but differing from the latter in that all the power is transmitted by gears, while the Central's locomotives are gearless.

It is evident that the greatest work done by the gearing on any locomotive is during the period of acceleration, and that for a given mileage the total amount of work done will depend upon the rate of acceleration, weight accelerated per gear, and total number of such accelerations or starts. During the evening rush hours in the New York Subway, the total load per gear is about thirty-five tons, and this weight has to be accelerated at the rate of 1.25 miles per hour per second every third of a mile, that being about the average distance between stations.

How serious a matter the breakage of one gear in the rush hour becomes will at once be realized when we state that at one of the many stub-end terminals of the system thirty-seven trains in and out per hour are handled during the period of maximum traffic. For the purpose of comparison the train movement at the Grand Central Station of the New York Central Railroad may be cited, the maximum number of trains there being thirty-five per hour, and this is, we believe, considered rather extraordinary congestion. One such breakage in the evening rush hour therefore means an inevitable delay to service of half an hour or more and the disruption of the train schedule for the rest of the day, thus entailing great discomfort to the traveling public.

Both the elevated and subway trains of New York are operated by the Interborough Rapid Transit Company, and there is no doubt that the conditions under which these trains operate are unique, further evidence being furnished by the failure of various apparatus other than gears which had proved entirely successful on other roads. We believe, therefore, that the data obtained by this company may be taken as measures of the limitation of power transmission by gearing in railway service.

As is probably familiar to all, the electrical operation of the Manhattan Elevated was commenced some three years previous to the opening of the New York Subway, and our earlier experience was therefore with the equipment for the former. The initial gearing installation on the 125-horsepower motors consisted of wrought-steel pinions and solid cast-steel gears of three-diametral pitch, this pitch being adopted on account of the economical current consumption thereby obtained. The pinions at once began to fail at the rate of about fifteen per month. The failures continuing, it was decided to withdraw all of the gearing then in service and replace it with two-and-one-half pitch, on account of the greater tooth section thereby obtained, although, as before stated, this meant some loss in economy of current consumption. This change practically ended the failure of the pinions, but not entirely of the cast gears, and it was decided that greater reliability could be obtained by adopting a composite type of gear consisting of a cast-steel center on which a wrought-steel rim was shrunk. This combination of a wrought-steel pinion and wrought rim gear of two-and-one-half pitch has proved generally satisfactory for the elevated service, and the improvement to be looked for is therefore in the line of greater wearing life.

On the subway division the motors are of 200 horsepower each and the original gearing equipment consisted of solid cast-steel gears with wrought-steel pinions, diametral pitch two-and-one-half, and teeth of the Brown & Sharpe standard fourteen-and-one-half-degree involute. As on the Manhattan division, so on the subway, it soon became evident that the design was not proper, but in contrast to the elevated road it was the gears which first caused the trouble. The cast-steel gears, therefore, were all scrapped and replaced by the wrought-rim type.

This improvement practically ended the gear breakage, but unfortunately the pinions began to go, the breakages averaging over one a day, and, furthermore, we find it unsafe to run a pinion the teeth of which measure less than three-sixteenths inch at the top. We are, therefore, compelled to scrap material which should be available for wear.

To what, then, shall we look as a remedy? Three suggestions have been advanced by the gear manufacturers:

a. Diametral pitch less than two-and-one-half.

b. Steel with elastic limit of 90,000 pounds per square inch and over, as compared with our present 45,000.

c. Twenty-degree stub teeth.

The first suggestion we are unable to accept on account of some local conditions, but the combination of the other two seems to have possibilities of success, and we are now replacing all our gearing with specially treated carbon steel with stub teeth. Let us now consider the loads the teeth have to carry and determine why it is that we have to resort to the use of special designs and material in order to make our gearing stand up.

Fig. 1 illustrates an express run in the subway, giving the power consumption per train of eight cars, five of which are motor cars, each carrying two motors, thus making ten gears per train. On the same diagram curves are platted showing the fiber stress in a standard fourteen-and-one-half-degree involute and a special twenty-degree involute tooth, both worn to our present limit of three-sixteenths inch at top of tooth. The force acting at the pitch line of the tooth has been figured from the power-consumption curve and the motor.

Referring to the diagram, it will be noted that the worst condition occurs just at the commencement of the motor curve, this being the point at which the gearing is transmitting the maximum torque at the greatest speed obtained during the period of acceleration, the maximum torque occurring, of course, only during this period. Under the conditions shown the fiber stress at this point is 13,370 pounds per square inch in the standard fourteen-and-one-half-degree involute tooth, and at this instant the train is running at 17.3 miles per hour, with a corresponding gear speed of 1,168 feet per minute. On account of this speed, therefore, we require a material which will permit the use of a safe working stress at no speed, equal to 39,400 pounds per square inch. The elastic limit of the material

[1] Abstract of a paper presented at the annual meeting of the American Society of Mechanical Engineers, at New York, December 3.

we have had heretofore runs about 45,000 pounds per square inch, and we therefore have a factor of safety of only 1.1, which is obviously low.

In these calculations we have considered the elastic limit of the material rather than the ultimate strength, on account of the dynamic character of the load, each pinion tooth receiving nearly 1,800 blows per mile. The greater the ratio, therefore, between the fiber stress and the elastic limit of the material (the other physical properties remaining of proper value), the greater the life, and some relief should therefore be obtained by the adoption of the special twenty-degree stub tooth which reduces the fiber stress nearly thirty per cent and increases the minimum factor of safety from 1.1 to nearly 1.6.

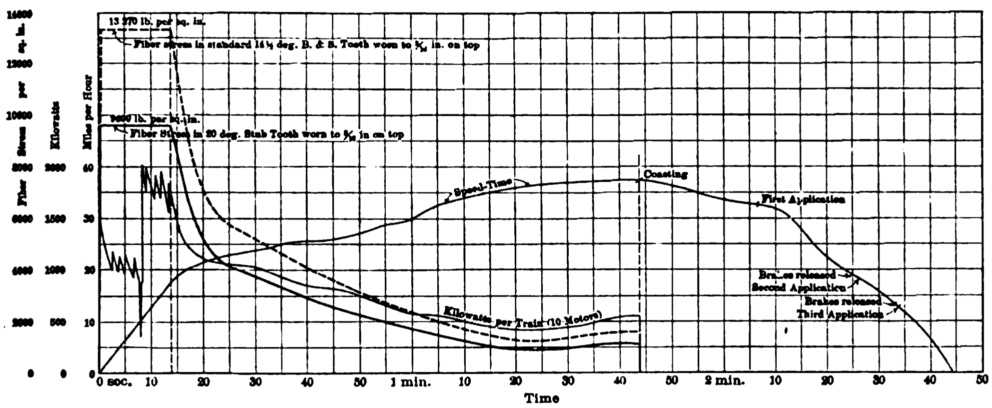


FIG. 1.—STRAINS IN TEETH DURING EXPRESS RUN—SUBWAY DIVISION, INTERBOROUGH RAPID TRANSIT COMPANY, NEW YORK CITY—CALCULATED BY LEWIS METHOD.

A much greater relief, however, may be looked for by the use of steel with a high elastic limit, say, 90,000 pounds per square inch, which, used in conjunction with a design of stub tooth, increases our minimum factor of safety to 3.2 as compared with our present 1.1.

It will be noted that the foregoing calculations are all dependent upon the use of the Lewis formula, the fundamental assumption of which is that the teeth bear across the whole face. Consideration, however, must be given to the fact that in practice it is not possible always to maintain perfect alignment between gear and pinion on account of the necessarily rough design of the motor and its assembly on the truck. The effect of this disalignment is shown in Fig. 2, which is a photograph of a pinion which broke in service. In this the lower half of the teeth have been battered over by the loose piece jamming between the gear and pinion. It is the upper half of the teeth which cracked, however, showing that these cracks were not caused by the jamming of the loose piece, but by the gradual hammering of the pinion against the gear in service. The points gave away successively, until at last the loose piece was caught and ripped out, and we find this typical of all the failures. The break ordinarily starts at the inner face of the pinion, due to the natural tendency of the armature to cock that way, but in some cases it starts at the outside, probably caused by running a new pinion with a gear which had previously worn taper.

Furthermore, the breakages cannot be attributed to so-called crystallization or "gradual fracture," for in many instances the teeth are practically new having broken after inconsiderable mileage. The necessity of having a high ratio between the theoretical working stress and the elastic limit thus becomes evident and justifies us in the adoption of the special means we have described to overcome the abnormal failures.

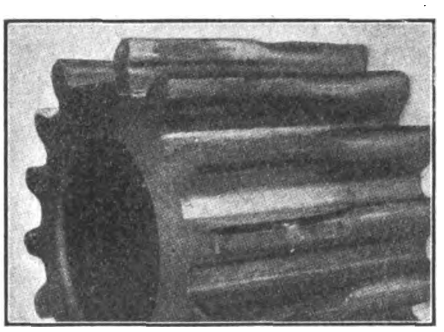

FIG. 2.—THREE-QUARTER VIEW OF PINION, SHOWING CRACKED TEETH.

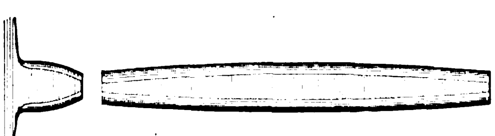

FIG. 3.—SUGGESTED FORM OF TOOTH.

The lack of alignment of gear and pinion above mentioned is probably one of the chief causes which necessitated the use of these special means, and we have therefore endeavored to find some other method of overcoming the difficulty. This led to the suggestion that as we are actually obtaining only a short bearing on the tooth, it would be better to assure this bearing being at the center of the face rather than at the end, which might be accomplished by the use of a tooth something as shown in Fig. 3, in which the central portion is left the standard outline and the balance tapered off both ways toward the ends. No investigation has been made as to the practicability of cutting such a tooth or of its desirability, and it is suggested for consideration merely as one possible way of compensating for the lack of alignment occurring in railway-motor gearing.

Electric Tramways in Germany.

United States Consul-General Richard Guenther writes as follows about the electric tramways of Frankfort:

The Frankfort electric-tramway lines at the close of the fiscal year (1907) had a length of thirty-eight English miles and carried during that year 74,250,000 passengers. There are 612 cars for the passenger service, and the total number of employes is 2,124. As most of these are married, the Frankfort tramway service furnishes means of living for about 10,000 people. On an average the electric cars run over 30,000 English miles per day. During the great International Turner festival last July the number of miles run on some days exceeded 60,000. Though the fares are lower than in American cities (ordinary fare is ten pfennigs, not quite two and one-half cents), yet the net profit derived from the service turned into the municipal treasury was 1,315,000 marks ($312,970). The profit realized during the year by the city from its electric lighting and testing plant aggregated $400,200.

The stride tramway travel has taken in Frankfort in the last decade can be discerned when comparing the above statistics with those of 1897, when the city bought out the then-existing horse-car lines which belonged to a Belgian joint-stock company. Then the total length of line was nineteen and one-fourth miles, number of cars 197, which carried during that year 26,500,000 passengers and covered a running distance of 3,375,000 English miles.

A new high-speed trolley line is to be built from Boston to Beverly at a cost of $11,000,000, to be known as the Boston & Eastern Railway. A 7,200-foot tunnel is to be built under the harbor at Boston costing $2,750,000.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

THE COST OF OPERATING ELECTROBUSES.

The London Electrobus Company, Limited, has recently issued a subscription circular asking the shareholders of the company to contribute $250,000 to a new issue of stock. A letter accompanying the prospectus gives some interesting figures dealing with the cost of operation. The company started service with six buses, in July, 1907, and in the first three months 179,909 passengers were carried. In the three months from July 15 to October 15, 1908, 925,959 passengers were carried. Over a period of fifteen months, from July, 1907, to October, 1908, the average number of passengers per bus has been nearly eleven, and the earnings about twenty-eight cents per bus-mile. In connection with the maintenance of storage batteries, it is stated that, with the exception of a few experimental batteries, the entire battery maintenance has been done under contract at four cents per bus-mile; that these contracts are still in force, and that offers have been made to maintain 100 electrobuses at the same rate for three years. The statement issued by the company's auditors makes it appear that the earnings during the first twelve months exceeded operating expenses by $3,714.54. This fell short of the establishment and overhead expenses. For the three months, July, 1908, to October, 1908, the earnings exceeded the operating expenses by $7,632.18, which is about sufficient to pay the establishment and overhead expenses. These expenses, it is stated, would not be materially increased if the number of buses were doubled, and the experience of the company indicates that as the number of carriages has been increased, the takings per bus-mile have also increased. From the auditors' statement it is found that for the year ended July 15 the number of passengers was 1,596,831. The total receipts were $43,638.18. The average receipts per bus-mile were 27.6 cents, and the total operating expenses were $39,923.64. For the three months ended October 15 the total income was $25,034.20, and the income per bus-mile 28.76 cents. These figures do not include provision for establishment, supervision or head-office charges, nor repairs to buildings. The total of these, excluding depreciation, for the same three months, was $7,582.89.—*Abstracted from the Electrician (London), November 20.*

THE MANUFACTURE OF METALLIC LAMP FILAMENTS.

In the present installment of this serial, which has been previously referred to in

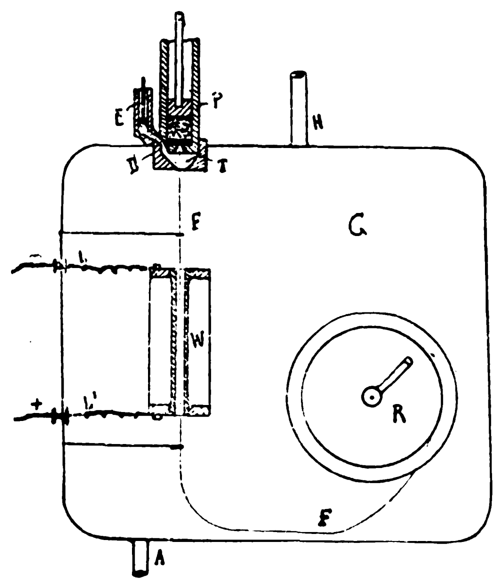

FIG. 1.—PROCESS OF MAKING METALLIC FILAMENTS.

these columns (ELECTRICAL REVIEW, November 21), Engineer B. Duschnitz describes the arrangement employed by

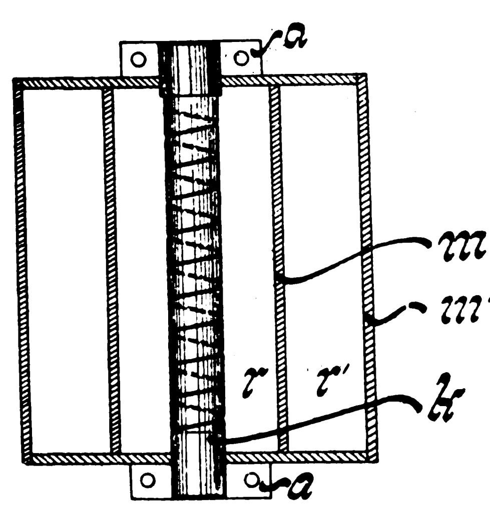

FIG. 2.—ELECTRIC FURNACE FOR THE MANUFACTURE OF METALLIC FILAMENTS.

Gebrüder Ruhstrat, of Goettingen, for manufacturing metallic filaments. The object of the arrangement is to lead the filament, consisting of wolfram oxide, for instance, through a furnace heated to about 2,000 to 2,700 degrees, and put it through the complete fusing process therein, and when it has passed through the furnace and is still aglow and flexible, to wind it on a spool provided for this purpose or cut it into definite lengths. By the aid of suitable means the filament can also be wound directly on frames to be inserted in lamps. The arrangement is diagrammatically illustrated in Fig. 1. P is a filament press, W an electric furnace, G an enclosure, through which hydrogen is made to flow and which contains the furnace and winding device, and L and L′ are conductors leading the current to the electric furnace. The method of manufacturing the filaments is as follows: The press P is filled with wolfram oxide paste and a thin filament F is pressed from it, led through the hot furnace W and wound on the spool R or a frame, or else cut into definite lengths. The case G protects the entire arrangement from the air and is filled with an indifferent gas, as hydrogen, which is injected at H and withdrawn at A. If very thin filaments are to be pressed, the auxiliary cylinder E is filled with a suitable binding material, which is pressed through tube D into the space T, where it covers the filament issuing from press P, in order to give it greater strength before it is fused. The furnace is of special construction. The heating body *k* (Fig. 2) is a carbon tube cut lengthwise into a spiral of a pitch of about ten millimetres. The space *r* is filled with heat-resisting material consisting of 100 parts of coke, eighty parts of sand and twenty-six parts of table salt. This mass is enclosed in a protecting covering *m*. The space *r′* is filled with a mixture of magnesia and carbon, and a second covering *m′* surrounds the entire furnace: *m* and *m′* consist of asbestos. Metal plates *a a* are provided for attaching the electric conductors. According to Ruhstrat's statements the filament is moved through the furnace at the rate of two millimetres a second. The arrangement would thus be capable of manufacturing a filament 7.2 metres long in an hour, sufficient for about twelve lamps of 100 volts and twenty-five candlepower.—*Translated and abstracted from Elektrotechnischer Anzeiger (Berlin), November 8.*

THE ELECTRICAL INDUSTRY IN ENGLAND AND ABROAD.

For the topic for his presidential address before the Institution of Electrical Engineers of Great Britain, on November 19, W. M. Mordey made a comparison between the condition of the electrical industry in England, as indicated by statistics of returns relating to electricity supply, with the electrical industry in other countries, particularly in Germany. He took exception to the repeated statements that England was in a backward condition as compared with other countries in respect to practical application to the industrial and social requirements of the nation. As a basis for comparison, Mr. Mordey said that it was necessary only, so far as the service of the public is concerned, to find the extent to which the systems of supply of electrical energy in different countries provide for the requirements of the public; in other words, to find the average consumption in units per inhabitant, and the average price per unit actually paid. Tables giving this information for a large number of towns in England and abroad, particularly in Germany, based upon what are essentially authoritative data, were examined, and this information supplemented with particular references furnished in response to his own applications. Mr. Mordey concludes that in the large towns in Germany electrical energy costs twice as much per unit, and the consumption per inhabitant is half as much as in the large English towns. In the medium-sized towns, the price in Germany is thirty-three per cent higher than in England, and the consumption is about the same as in the medium-sized English towns. In the small towns in Germany the price is forty per cent higher, and the consumption about the same as in England. The public generating stations contain two-and-one-quarter times as much power per inhabitant of the whole country as those of Germany. In electric-tramway work England does not compare unfavorably. Only where the advantage of cheap and ample waterpower in a few places has enabled an extensive supply to be given at low prices, notably in Lyons, Geneva and Grenoble, does any advantage exist. But in this direction also a British town, Bolton, with an average of 2.36 cents per unit, has the cheapest supply. Mr. Mordey considers that there is nothing in British electrical work to justify in any way the charges that have been made against it. The alleged backwardness does not exist. The country is ahead, and well ahead. There are hindrances, legislative and otherwise, to going still further ahead, but there is no more justification for the statements about scientific and technical education being behind other countries than for the statements about the backwardness of British electrical engineering. Technical education should be judged, not by the wealth of the equipment of laboratories, but by the engineering results achieved in the country.—*Abstracted from Electrical Engineering (London), November 26.*

ALTERNATING-CURRENT TELEPHONY.

Attention is called by the author, August Maior, to the importance of alternating currents in telephony over lines of any length. While engaged in experiments on the application of alternating currents to multiple telephony, he observed that, in general, the speaking currents superimposed on the alternating currents are of a more complicated form and are not an exact reproduction of speech. The rattling and long-drawn sounds assume more nearly their natural character the closer resonance is approached. The frequency of the currents employed is of great influence on the clearness of speech, and a perfectly clear reproduction of the sounds is attained only when a frequency is used which no longer audibly affects the diaphragm of the telephone receiver. The intensity of the sounds is also greater with the higher frequencies. But if, eventually, a microphone which is in series with another self-inductionless resistance, is connected in parallel with the self-induction coil of the resonating alternating-current circuit, very great variations in the strength and period of the alternating current may be produced by slight changes in the suitably-chosen parallel resistance without self-induction. In this manner the problem of the telephone relay can be most easily and most naturally solved. If the alternating current is in resonance, the speaking currents superimposed on it are virtually also in resonance, and in this way the injurious influence of self-induction and capacity of lines of any length can be easily removed, the damping constant being diminished as much as possible without impairing the strength of the transmitted sounds, which may even be increased, as before indicated. This is not always possible by the insertion of Pupin coils in the line, as is well known.—*Translated and abstracted from Elektrotechnische Zeitschrift (Berlin), November 19.*

ALUMINUM AS A CONDUCTOR IN THE ELECTRICAL INDUSTRY.

In Great Britain the employment of aluminum as a conductor has not had much vogue, though in the United States it has been used to a great extent for some time. The Niagara, Lockport & Ontario Power Company uses an aluminum transmission line from Niagara to Syracuse, a distance of 162 miles; while the Standard Electric Company, of California, has an aluminum transmission line 200 miles long. That aluminum has not been used to a greater extent in Great Britain is not altogether a matter for surprise. In the first place, there is the well-known British inertia to be overcome, while, owing to the meagre adoption of overhead work for public supply, it has hardly received proper consideration. The question whether it can be economically used for cables is an interesting one, comprising many interesting factors. During the past two years the price of copper has fluctuated between \$560 and \$270 per ton. Though to some extent disturbed by this variation, consequent on a demand which the manufacturers were not able to meet, aluminum is now available in any quantity, and its price has been reduced, until today it is quoted at the same price per ton as copper. As, however, for equal conductivity, only half the weight of aluminum is required as of copper, a net saving of fifty per cent on the cost of the raw material is effected by employing the former metal. In the installation at Snoqualmie Falls, where 12,000 horsepower is transmitted by aluminum conductors, some thirty-two miles to Seattle, and forty-four miles to Tacoma, in the state of Washington, the spans between the poles vary from 120 to 150 feet. From Electra to San Francisco, in California, the poles are about 130 feet apart, and the distance over which power is transmitted is 154 miles. The maximum span reached by aluminum conductors is 2,192 feet, across the Niagara River.—*Abstracted from the Electrician (London), November 27.*

Dr. Steinmetz to Lecture in Chicago.

At the special invitation of the Chicago Section, American Institute of Electrical Engineers, Dr. Charles P. Steinmetz will deliver a lecture on "Light and Illumination" at 8 p. m. on December 17, in Fullerton Hall, Art Institute. All members of the Chicago section, as well as the local branches at Armour Institute of Technology and Lewis Institute, are urged to attend and bring their friends with them.

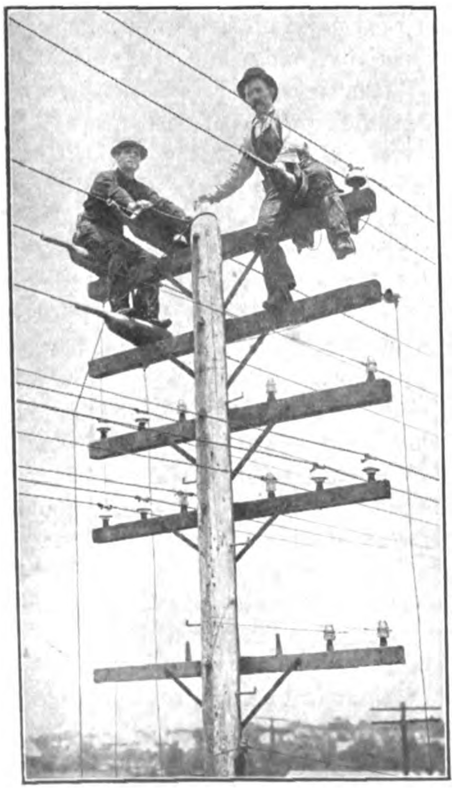
INDUSTRIAL SECTION

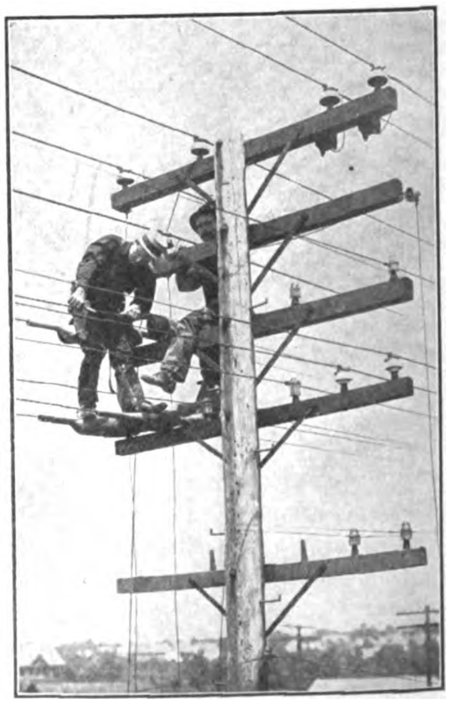
ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

A Linemen's Protective Shield.

In these days when every effort is being made to safeguard life and limb, the introduction of a shield which will minimize the dangers to linemen working on live high-tension circuits attracts considerable attention, and is worthy of specific illustration and description.

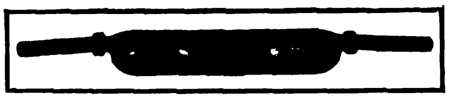
The shield which is being manufactured by the Linemen Protector Company, 201 Whitney Building, Detroit, Mich., is one of the most useful devices which has been developed in recent times. The accompanying illustrations show the protective shield and the method of using it on high-tension circuits. The shield is made of pure Para rubber, no reclaimed rubber being used. The pure rubber is carefully washed and processed so as to eliminate any possibility of impurity either in the form of sand or metal, as before the completed shield leaves the factory it must withstand very high pressures in the molding process, and a puncture test of 30,000 volts, alternating current, under water.





VIEWS SHOWING THE LINEMEN'S PROTECTIVE SHIELD IN USE ON HIGH-TENSION LIVE WIRES.

The main portion of the shield is made of three-eighths-inch rubber, tapering down at those extremities which are least required for insulating value to three-sixteenths of an inch. In order to give the shield sufficient rigidity and to make it tend to hold its original shape and fit closely over the insulators and wires, heavy strips of raw canvas are criss-crossed, and this method of laying up the canvas strips also avoids the possibility of puncture from a tool or from the lineman's spur.



THE LINEMEN'S PROTECTIVE SHIELD.

In using the shield it is hoisted from the ground, weighing complete only seven-and-one-half pounds to eight pounds, and is gripped by means of soft-rubber handles attached to the lowermost outside point of the bifurcated apron. This keeps the wireman's hands from possible contact with either the insulators, tie wires or live circuit.

In order that the shield may be held firmly to the wire a split hard-rubber ring having a helically-inclined half-inch gap, so that it may slip easily over the wire, is fitted over the small ends of the shield, resting snugly against the larger portion of the shield. While this slips on and off easily by a smooth, even movement, any tendency to jerk it off causes it to grip the shield very tightly. This is a great advantage, because at times the lineman will stand on one shield which may be placed over a cross-arm and wire lower than the point at which he is working. Should he slip and the heel of his boot come in contact with the split ring it will immediately check the slipping, and will form a brace for his foot.

The shield is recommended by the manufacturer for use on all live circuits not exceeding 7,500 volts. It is in use, however, on circuits as high as 10,000 volts. In wet weather it is not desirable perhaps to use the shield on circuits carrying voltages higher than 4,600, as in this case the static leakage over a wet shield might give the lineman sufficient shock to throw him off his balance and into contact with an unprotected live wire, or possibly cause him to fall to the street. It is stated that it is a fact that the shields have been used on 4,600-volt, three-phase circuits under all weather conditions, and that with their use it has not been necessary to cut out circuits in order to make taps or effect other repairs.

While the device minimizes the possibility of unintentional contact with other wires on the same pole, there is the chance that the lineman may rely too much upon the protective quality of the shield and subject himself unnecessarily to danger from live wires. Where the shields have been adopted, however—and they have been by a number of large companies in several sections of the country—it has been found that the linemen have accepted them in the same spirit as they have accepted climbing spurs and heavy belts, and other protective devices. It appears that the older and more experienced the lineman is, the more readily does he adopt the protective device; and its utilization appears also to be an indication and a warning on the part of the company that the circuit to be protected is dangerous, and that the lineman, in addition to utilizing the safeguard provided, must also exercise that care which is necessary to eliminate the possibility of danger to himself.

The accompanying illustrations, showing the shield in use, were made from photographs taken during work on live circuits carrying 4,600 volts, three-phase. An affidavit is in the possession of the manufacturer, stating that current was on all three wires shown covered by the shield, and that it was not shut off during the time the pictures were taken or while the work was being done.

Intercommunicating Telephone Systems.

In the December issue of the *Everbest Magazine,* published by the Ewing-Merkle Company, St. Louis, Mo., A. R. Forse, manager of the telephone department, gives some interesting information concerning intercommunicating telephone systems.

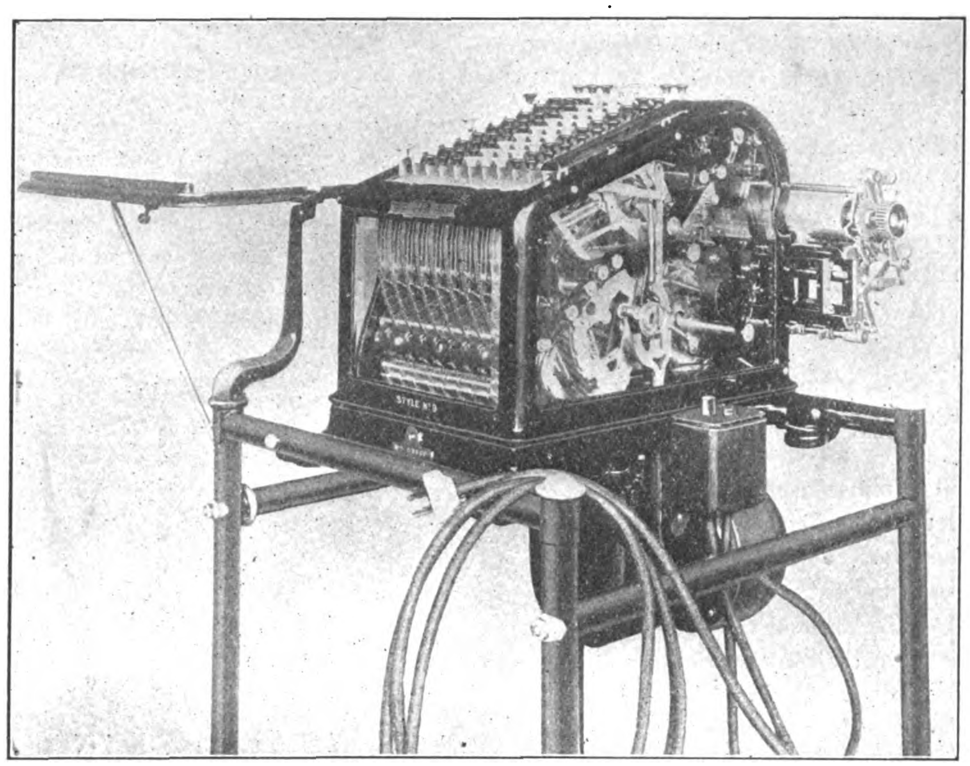
The installation of a good intercommunicating telephone system is somewhat more expensive in first cost than a private branch exchange would be, but the first cost is practically the only cost in the intercommunicating system, with the exception that about every six months there should be a new set of batteries installed, so that the service may be first class in every particular. Junction boxes should always be used wherever a cable is to be spliced. Where it is necessary to cross from one building to another, or through sections of the same building that are damp, weatherproof wire should be used; but where the lines run through ordinarily dry places, annunciator cable having a weatherproof tape and a braid overall may be used. Cable in which each wire has a distinctive color covering is preferable, and saves time in testing. Most of the systems now use four battery wires—two for the ringing batteries, and two for the talking batteries—and one wire for each station installed. Thus, a system having ten telephones would have a cable containing fourteen wires. The battery wires are usually several sizes larger than the others. For systems in which not more than 300 or 400 feet of cable is used, battery wires of No. 18, and line wires of No. 22 are generally used, with slightly heavier wires for longer distances, using four batteries on the talking wires and six on the ringing wires.

An Electric Motor-Driven Adding Machine.

Everyone has experienced the feeling of disgust caused by the expenditure of time and energy in the actual performance of long arithmetical computations necessary to obtain a desired result. Being compelled to devote close attention to a series of operations, which in themselves are extremely simple and require comparatively little intelligence is, to say the least, irksome. Then as the latter feeling increases, the liability to error becomes greater, until there is a definite limit to the amount of such work which may be done by a single computer.

The pertinence of the expression, mechanical computation, is evident when it is considered that this can actually be performed by mechanical computers, or "adding machines"; it has been stated that the number and complexity of the arithmetical operations which can be thus performed are only limited by the mechanical difficulties in the construction of the machine, which increase very rapidly as the number of possible operations is increased. The higher faculties of the human mind can never be replaced by a mechanical contrivance, but in large part the purely calculating power may. Oliver Wendell Holmes remarks that "the calculating power alone should seem to be the least human of qualities, and to have the smallest amount of reason in it, since a machine can be made to do the work of three or four calculators, and better than any one of them."

The ordinary form of adding machine will do adding, subtracting, multiplying and dividing from four to six times as fast as an expert. It is not possible to make errors in the actual performance of the computations, and during operation it does not require the close attention which the human computer must necessarily give his work. By its use, in connection with the card systems and other short cuts devised for especial use with the machine, the efficiency can be much increased. The only mechanical work necessary is the pressing of the keys and the operation of the handle projecting to the right of the case, and the latter has been eliminated in the improved forms by the application of the electric motor.



MOTOR-DRIVEN ADDING MACHINE.

The illustration shows perhaps the most popular adding machine, the Burroughs, equipped with a Westinghouse motor. With this improvement the number is written without any mechanical labor by simply pressing a key on the keyboard of the machine, which throws in a clutch and connects the shaft of the motor with that of the handle. When it is considered that the manipulation of the handle is the only thing in the operation which is tiresome and that this causes a material interruption of the work, it will be seen that the application of the electric motor is a very material advantage. In fact, experiment has shown that the operation is forty per cent faster, with less liability to error caused by setting the incorrect number and less labor on the part of the operator when the machine is thus driven.

The motors used with this adding machine have capacities of one-tenth or one-eighth horsepower, the former being used with a machine of seven figures and the latter with one of nine figures. They run at a speed of about 1,200 revolutions per minute, and are furnished for either direct or alternating current. The cost of the operating energy is insignificant, varying from one to two cents an hour, according to the local rates for electric energy. No special wiring is necessary, the motor can be connected to an ordinary lighting circuit as readily as an incandescent-light bulb. The motor will run continuously without attention, an occasional oiling once in several months being only necessary.

Western Electric Company Completes Paris Switchboard.

The replacement of the destroyed Paris telephone switchboard, as described and illustrated in the issue of November 21, was completed according to specifications November 30 and the $600 daily penalty clause in the contract, for every day over sixty days required in building this switchboard, was thus rendered inoperative.

The Chicago plant of the Western Electric Company started work on the big switchboard October 3, shipped it to New York on October 23, and it arrived in Paris on the steamship La Provence November 6.

This is the second record made within a year by the Western Electric Company for rapid telephone-exchange replacement; the other being that of the Antwerp exchange—the oldest in Europe—for which a 5,000-line equipment was manufactured and installed in thirty days. The Paris contract covered a 10,000-line equipment and, while apparently involving but twice the labor of the other, in reality meant several times more. The fast time made stands as another triumph for American skill and enterprise.

PREVENTING THEFT OF CURRENT.

BY H. W. YOUNG.

Theft of current with the many and varied methods by which it is practiced, presents a most interesting, as well as harassing, problem to central-station

FIG. 1.—SERVICE PROTECTED.

companies, many of whom have perhaps not given the subject the consideration or attention which its seriousness demands.

The larger electric-lighting companies are giving this subject careful thought, and large sums of money have been recovered in some cases, but only by an

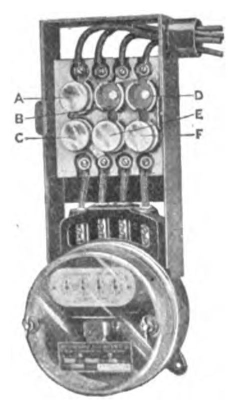


FIG. 2.—TESTING OR INSPECTING SERVICE.

elaborate and expensive spy and detective campaign. That such a system, entailing as it does large expenditures, is justified by the results which have been obtained, many of the companies will testify.

The central-station man, familiar with the fact that the majority of those who will steal current are of the class whose credit involves a deposit before the installation of the service, will appreciate that the list is not, however, entirely confined to this class. A man will hesitate before he will deliberately remove the insulation and make a permanently illegal tap on a service wire, but few will hesitate to connect a flexible cord to an exposed branch block or service switch, when it is necessary to have temporary illumination in some obscure corner, and which will probably prove to be so handy as to remain permanent. Also, but few will hesitate to connect a discontinued service to the branch block when for any reason they wish light, and it is not otherwise instantly available.

A surprisingly large number of connections of this character have been discovered in apartment houses, where meters are removed during the summer months, and the electric-lighting company is not able to connect the service as rapidly as desired.

The average central-station man, with a broad and abiding faith in human nature, will ponder over unaccounted-for current losses, and wonder how much the human equation is a factor in the phenomena of current transmission, particularly so as it has been discovered that the curve of current losses flattens materially in feeders, the service wires of which are carried in conduit directly into the meter, with entrance box and meter connections protected by seals that successfully serve their intended purpose.

The problem is not how to apprehend people who are stealing current and bring them into court, but to remove temptation, increase metered output, and eliminate legal complications that add very greatly to a station's cost of production and frequently engender a hostile feeling in a community which really does not understand the facts of the case.

Appreciating the need of coping with this phase of central-station trouble, the Central Electric Company, Chicago, and the Pettingell-Andrews Company, Boston, have marketed a number of devices designed to cure this evil, one of the best known being the "O. K." connection block illustrated in Figs. 1 and 2.

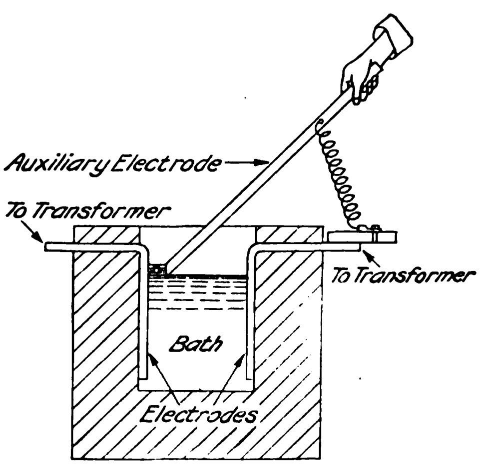
Where it is desirable and practicable to carry the service wires in conduit this connection block offers a means of terminating the conduit at the meter and taking the wires into and out of the meter without leaving any exposed leads or connections. The enclosing box is so made that line and load wires may be brought in on either side as desired. It fits snugly against the meter, protecting one or more of its supporting screws, so that it is impossible to disturb the meter connection or remove the meter from the wall without breaking the seals of the connection block cover.

In the view showing the connection block with the cover removed, the screw plugs designated by various letters are not necessarily fuse plugs, but switch-connecting means, which enable the inspector to make any desired test on the meter without cutting a wire, opening a taped joint, or interrupting the customer's service. By screwing the connection plugs into receptacles B, D, the meter is by-passed and the customer's lights kept burning. Removing the plugs ACEF entirely disconnects the meter from both load and line and permits its removal or replacement without the necessity of a soldered joint or any tool other than a screwdriver.

Any desired commercial or house test can be made by means of this connection block, and its use in laboratory work greatly facilitates meter testing, etc., because of the facility with which any desired connection or combination of connections may be made. This particularly applies to the testing of one or more meters in connection with a standard where it is desirable to remove a meter from its connection without disturbing the others.

A New Electric Furnace for Annealing and Tempering.

To secure the best results in the process of annealing and hardening, it is necessary to have a constant temperature in the furnace. The coal and gas furnaces of today do not entirely fulfill this requirement on account of the large furnace area exposed to the air for radiation.



SECTIONAL VIEW OF ELECTRICAL FURNACE FOR ANNEALING AND TEMPERING.

Again, to obtain the best results, it is often necessary to adjust the temperature of the furnace, and this cannot be done with precision with the gas furnace. Realizing these facts, it is natural that tool producers and manufacturers in general should look forward to the day when a hardening furnace would be designed that might assure them better results in a shorter time than is possible with present methods.

In the new type of electric furnace now being manufactured by the General Electric Company, Schenectady, N. Y., for operation on alternating-current circuits, metallic salts are reduced to a liquid state by means of an electric current. It can be readily seen that as soon as these salts reach a liquid condition, the temperature can be easily regulated by varying the amount of current passing through the bath. By this method of regulation any temperature from 250 to 1,350 degrees Centigrade may be obtained. The temperature will remain uniform throughout the bath except at the surface, where it is slightly lower, due to radiation. This applies, however, only to a depth of 0.6 to 0.75 inch.

Herewith is shown an electric-furnace outfit as it is installed in the die department of the Schenectady works of the General Electric Company. The outfit, as can be seen, consists of the furnace, with its hood suspended from above; the regulating transformer with regulating switch; the switchboard with the necessary ammeter and voltmeter; the incoming line with fuses. The regulating switch is provided with a sufficient number of contact points to give, as stated

ELECTRIC FURNACE FOR ANNEALING AND TEMPERING.

before, almost any desired temperature between the limits of 250 to 1,350 degrees Centigrade.

The furnace, a sectional view of which is also shown, consists of a fire-clay crucible, surrounded by an insulating material, usually of asbestos, which rests in a fire-clay box; all being supported by an enclosing case of iron. Two suitable electrodes, connected to the low-tension side of the transformer, are placed on each side of the crucible, and are in direct contact with the bath at all times.

To start up the furnace an arc is started across the broken flux by means of an auxiliary electrode, and in a very short time the solid mass is in a molten condition. After the bath has reached its proper temperature, that portion of the material to be hardened is placed entirely in the liquid bath, and is allowed to remain there until it attains the same color as the bath, when it is removed and tempered in water or oil, as the case may be.

The bath for hardening or annealing completely fills the crucible, and in the Schenectady factory consists of equal portions of barium chloride and potassium chloride. The ultimate temperature depends on the relative proportions of the two chlorides, the higher the percentage of barium chloride, the higher the temperature may be carried.

In addition to hardening, the furnace may be used for softening tempered steel, the bath being maintained at a temperature of about 250 degrees Centigrade for this work.

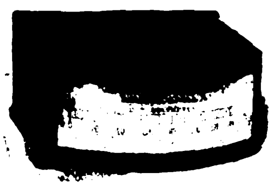
In summing up the advantages of this type of electric furnace, the following may be mentioned: There is no chance for oxidation, for the material while being heated does not come in contact with the air. All parts of the tool are subjected to the same degree of heat at all times, thus preventing any possibility of strains or overheating. Its high efficiency and low cost of operation place it far above the gas furnace. There is practically no danger from fire, as the outer walls of the furnace are never hot; in fact, when the bath has a temperature of 1,300 degrees Centigrade, the hand can be placed on the outside of the furnace without being burned. It is so simple and requires so little care and attention that it can be operated by an ordinary workman. The metallic salts have no effect on the composition of the steel, and the operator never comes in contact with dangerous fumes, as in the cyanide bath.

In the manufacture of machine tools, automobiles, razors, knives, firearms, jewelry, fine instruments, etc., this electric furnace bids fair to replace almost every other type of furnace that is called upon to meet the requirements of accurate tempering, according to the manufacturers, who have made thorough and practical tests of this apparatus.

Keystone Horizontal Edgewise Switchboard Instruments.

The Keystone Electrical Instrument Company, Ninth Street and Montgomery Avenue, Philadelphia, Pa., has placed on the market a new line of horizontal edgewise switchboard instruments. These are made in voltmeters, ammeters and wattmeters, for both direct and alternating-current circuits, and have been designed with particular reference to lighting and power switchboards where space is limited. They are secured to the board by the current-carrying lugs, so that only two holes need be drilled for voltmeters and ammeters, and four holes for wattmeters.

The instruments are neat and pleasing in appearance, and are mounted in plain cases. All cases are finished in dull black, this finish wearing indefinitely and requiring no attention beyond an occasional wiping with a soft cloth to remove dust. The scale openings are large, admitting ample light for reading at a distance. The form and location of the pointer are such that readings can be taken at a considerable angle without introducing appreciable parallax errors.



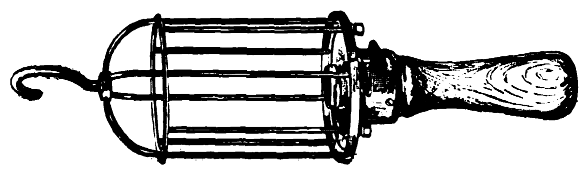
KEYSTONE HORIZONTAL EDGEWISE DIRECT-CURRENT VOLTMETER.

Voltmeters and ammeters for direct current are built on the Deprez-D'Arsonval system; voltmeters and wattmeters for direct and alternating current, on the electrodynamometer system; and voltmeters and ammeters for alternating current on the electromagnetic system. Wattmeters for alternating current are made for either single or polyphase circuits.

"Bulldog" Portable Lamp Guard.

For work requiring the use of an electric lamp in places where the globe is likely to be injured by the light falling or being struck by hard, heavy objects, some protective cage or guard is a necessity. In the design of such a guard it is essential for the comfort of the workmen that the guard metal be insulated from contact with any live parts in the socket.

Illustrated herewith is the "Bulldog" portable lamp guard, which is rigidly made, of Bessemer steel, copper-plated. The socket is provided with a key, and the handle gives perfect insulation. The bushing is large enough to take any size cord, and the guard will contain either a sixteen or thirty-two candlepower lamp.



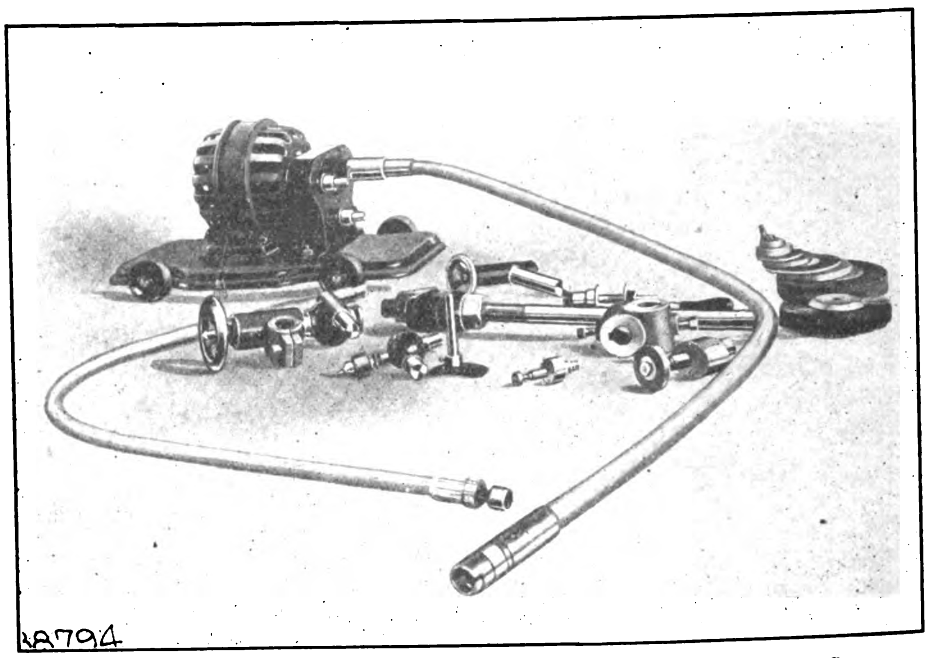
"BULLDOG" PORTABLE LAMP GUARD.

The guard is strong enough for the heaviest usage around engine rooms, machine shops, roundhouses, etc.

The Bulldog portable lamp guard is manufactured by the Crescent Company, 103 West Adams Street, Chicago, Ill.

Small Motor-Driven Emery Wheels, Buffers and Drills.

The illustration shows a handy motor-driven flexible-shaft outfit furnished the United States Government by the Coates Clipper Manufacturing Company, of Worcester, Mass. The equipment consists of a breast drill, drill press, emery wheels and polishers, and is provided with such necessary attachments as a multiplier, clamp, spindle, old-man, etc. The motor is a one-horsepower Westinghouse type CCL alternating-current motor mounted on a portable truck, and fitted with speed-changing head and flexible shaft. The portability makes the appliance convenient for any large work, and the flexible shaft permits the operator to work with ease upon parts otherwise accessible with difficulty.



SMALL MOTOR-DRIVEN EMERY WHEELS, BUFFERS AND DRILLS.

In order to obtain the proper cutting speeds for emery wheels of different diameters, multipliers of the proper ratios are used. The two which can be used to best advantage are those having ratios of eight-and-one-half to one and six-and-one-half to one, respectively; the former for use with three-eighths, one-half and one-inch wheels, and the latter for two and three inch wheels. Larger sizes are used on a clamp spindle, which runs at the speed of the shaft, 1,800 to 2,500 revolutions per minute.

By removing the breastplate on the drill and attaching a combination old-man, drilling up to one-half inch can readily be done. Larger drills up to one-and-one-fourth inches are used in connection with a worm-feed drill press and old-man attachment.

The outfit is so arranged that a heavy or light shaft can be used, according to the requirements of the work. The smaller shaft is fitted with a taper end sleeve for taking small tools, and the larger shaft has a clutch sleeve and grab-dog clutches, so that one tool can be used after another without making any change in the shaft.

Edison Phonograph Manufacture.

Announcement has been made at the works of the National Phonograph Company in West Orange, N. J., that the manufacture of Edison phonographs is in future to be restricted by the company entirely to West Orange, and that the industry will be withdrawn from the London, Paris and Berlin factories.

Current Electrical News

CONTINENTAL EUROPE.

(Special Correspondence.)

PARIS, NOVEMBER 28.—A very successful interurban electric road has been installed between Schaffhausen and Schleitheim. It uses a type of motor car operating at 750 volts, direct-current, and having a capacity of 200 horsepower, the train being generally made up of a motor car and one or more trailers. The electrical outfit for the line has been supplied by the Oerlikon Company. Passing through a number of localities, such as Beringen and Lohningen, the present line has a total length of eleven miles. It receives current from the municipal electric plant of Schaffhausen, whose transformers supply three-phase current at 10,000 volts. The Siblingen substation, where the three-phase pole-line terminates, contains the rotary groups for supplying direct current for the trolley wire. There are installed in the plant two rotary groups of 200 horsepower each, driven by Oerlikon three-phase motors working upon 380 volts, the secondary potential of the station step-down transformers. Connected with the three-phase motor is a multipole generator of the electric-railway type, which supplies 800 volts, direct current, for the car motors. A storage battery consisting of 390 cells and having a capacity of 200 ampere-hours is mounted in parallel with the generator bars. The motor cars measure fifteen metres between buffers and are mounted on double trucks. Each of the trucks contains two fifty-horsepower motors, making four motors per car.

Among the most recent construction work in the Swiss region may be mentioned the new Bernina electric tramway. The starting point of the line is at Tirano and the route lies along the Poschiavo valley, passing thence by the lake of the same name and Bianco Lake, reaching the mountain region of the Bernina Pass, about which it winds for a considerable distance, offering a fine view of the glaciers of this region. The line then descends to its terminal point at Pontresina. Current for the present line is furnished from the Brusio hydraulic plant, which is fed by the waters of Poschiavo Lake. In the canton of Berne there is a project on foot for the erection of a large hydraulic plant, which is intended to work in parallel with the existing station of Hagneck. For this purpose a dam will be built upon the Doubs stream, near the locality of Souby, at a point where the river is twenty-five metres wide. From the dam there will be run a tunnel flume to the site of the turbine plant at Ocourt. In this way there will be furnished a head of water of forty metres, and the proposed plant will utilize 5,000 horsepower. Of greater size is a proposed plant which is to utilize the power of the Linth River. The rights for such a plant have been already asked from the cantonal government, and, according to the present project, it is to furnish 15,000 horsepower. A tunnel through the Bernardin is one of the most recent projects and will be used to make a railroad connection in this part of the Alps. The enterprise is an extensive one and the project is drawn up by the Buss firm of Switzerland. It is probable that the railroad which runs through the tunnel will be operated electrically.

Messrs. Bellini and Tosi are continuing their experiments in the way of wireless telegraphy by means of directed waves, using for this purpose the main station located at Dieppe and two similar posts at Havre and Barfleur, on the Channel coast of France. By their new method they are quite successful in directing the waves to Barfleur, for instance, without having the same waves affect the station of Havre, which lies nearly in the same line. In this connection I may mention that the work of installing the new wireless station at the Eiffel Tower is making good progress, and it will not be many months before messages will be sent from the plant. A. DE C.

GREAT BRITAIN.

(Special Correspondence.)

LONDON, NOVEMBER 27.—The confusion which had developed in the case of the London electricity supply question has been somewhat disentangled by the result of the proceedings before the Parliamentary Committee, which has now completed its labors, and a certain amount of order has been evolved out of this chaotic condition by the substitution of the London County Council as the one purchasing authority in the year 1831 instead of the different local authorities at different dates.

The interesting experiment now being carried out at Poplar by the local medical officer of health, who makes an electrolytic disinfectant for distribution among the inhabitants, has been reported upon by the bacteriologist to the Local Government Board. This report, which has been asked for in consequence of certain criticisms upon the system, is entirely in its favor, and states that one ounce of the electrolytic fluid to about one gallon of water will kill cholera and typhoid germs in two-and-one-half minutes.

Mr. W. M. Mordey, as the president of the Institution of Electrical Engineers, in a recent address dealt with the alleged backwardness of Great Britain in the electrical industry compared with the rest of the world, and gave figures to show that compared with Germany the consumption of electrical energy is greater here. The present industrial depression he attributed purely to home reasons, and mainly to the fact that users of electrical machinery purchase too much from abroad.

The Great Western Railway Company, which was the first to adopt a system of audible signaling on its locomotives, with a view to abolishing the semaphore system, is now to install this system upon a section of its main line. The system signals are in character essentially electrical and were described in these columns some months ago.

Efforts at running electric cabs and electric omnibuses are apparently destined to meet with more or less unsatisfactory results in London. The Electromobile Company, which promised at one time to establish a very lucrative business in the West End in hiring out electrically driven cars of various descriptions, has suffered a loss of about $7,500 on the past year's trading. The Electrobus Company is also meeting some difficulty in raising its new capital through the public, while a prospectus for placing electric taxicabs on the streets of London did not meet such response as to warrant the directors going to allotment.

An action is being taken in the British courts by the Johannesburg Corporation against the contractors for the famous gas-engine plant there for damages to the extent of $2,000,000, which sum, however, includes the balance of the cost of the plant, which is claimed back. The defense is that the failure of the plant to come up to specification was the unsatisfactory coal used in it. G.

EASTERN CANADA.

(Special Correspondence.)

OTTAWA, DECEMBER 5.—The Brazilian Electro-Steel and Smelting Company of Toronto has been incorporated with a capital stock of $10,000,000. The provisional directors are those who usually appear in connection with the announcement of the incorporation of Mackenzie & Mann projects.

As regards the introduction of electric lighting by Canadian railways, both the Canadian Pacific and Grand Trunk railway companies are now carrying out duration trials on some of their cars. These cars have already covered a total mileage of over 1,000,000 miles without one report against them, and it is expected that similar installations will be gradually made until all the railway cars in the Dominion are thus equipped.

The sum of $1,500,000 from Chicago was deposited in a bank at Hamilton, Ont., this week to be used by the Independent Telephone Company. This company is already established at Toronto with a charter covering rights to operate out of that city, and within two weeks construction work will be commenced between Montreal and Toronto. The company is already formed, and interested Chicago people are now in Toronto, one of the party being a member of the Chicago firm of Marshall Field & Company. With this project is associated Eugene M. Beals of New York, who has sole rights for the "Telepost" system of telegraphing. W.

WESTERN CANADA.

(Special Correspondence.)

WINNIPEG, DECEMBER 5.—The electric light and power commissioners of Edmonton, Alb., have discovered that more power is urgently needed by the city. The matter will be taken up by the City Council and arrangements made for the enlargement of the municipal plant. Commissioner McNaughton may be addressed in regard to this matter.

Several important by-laws will be voted on by the ratepayers at the coming municipal elections at Fort William, Ont. The sum of $18,000 is required for extensions and improvements to the municipal telephone system; $10,000 for the extensions to the electric lighting system; $5,000 for the installation of a fire-alarm system, and $170,000 for extensions, double-tracking, etc., of the street-railway system recently acquired from Port Arthur. Address Mayor Murphy, Fort William, Ont.

By a large majority the ratepayers of McLeod, Alb., have voted in favor of spending $55,000 for improvements and extensions to the municipal electric-lighting system. Address E. F. Brown.

Despite the fact Edmonton, Alb., has a new telephone system, there is already a shortage in the supply of instruments, the demand for connections having greatly exceeded the provision made for subscribers. The Council will at once arrange for the purchase of additional equipment. Address Superintendent Cummings.

At Calgary, Alb., a company being formed has applied for a charter to build an electric railway system from that city to Millarville, a distance of twenty-nine miles. So far the names of the incorporators have not been made known. E. L. Richardson, Calgary, can give particulars.

The stringing of the wires to the Silver King mine, near Nelson, B. C., by the West Kootenay Power Company, has been completed. The intention of the owners of this mine is to use electricity entirely in the future.

Superintendent McCauley of Port Arthur, Ont., who formerly had charge of the municipal street-railway system, has been appointed superintendent of the municipal electric-light, power and telephone systems in Port Arthur.

The Kootenay Telephone Company, with head office at Cranbrook, B. C., has announced its intention of building a long-distance line from Corbin to McGillvray, B. C., in connection with the development promised by the Corbin Coal Company of Spokane, Wash. The company is also arranging for the construction of a number of lines in Canada in that part of the country due north of Spokane as well as a long-distance line through the Crow's Nest Pass country to connect with the government system in the province of Alberta. R.

OBITUARY.

MR. FRANK MILLER, manager for the Southern Bell Telephone Company, died at Nashville, Tenn., November 29. His home was at Le Sourdsville, O. H.

MRS. MARY J. NATE, who died December 2, at the age of seventy-two years, was the mother of J. J. Nate, the well-known representative of the Stromberg-Carlson Telephone Manufacturing Company.

A. V. SCHROEDER, general manager of the Winona Railway and Light Company, Winona, Minn., died of typhoid fever at Winona the latter part of November. Mr. Schroeder was formerly electrical engineer for the Illinois Traction Company, and prior to that was electrical superintendent of the Springfield (Ill.) Light, Heat and Power Company. He was a prominent figure in the organization of the Minnesota Electrical Association.

TELEPHONE AND TELEGRAPH.

(Special Correspondence.)

BRYAN, TEX.—The Bryan Telephone Company has increased its capital stock to $14,000.

YANKTON, S. D.—The Yankton Telephone Company will erect a new central office building. C.

ESSEX, IA.—The Farmers' Telephone Company has been organized with a capital stock of $15,000.

PARK, KAN.—The Park Telephone Company has been incorporated with a capital stock of $10,000.

BALSAM LAKE, WIS.—The McKinley Telephone Company has been incorporated. C. J. Porter is secretary.

BELFIELD, N. D.—Ed. O'Connor and others have incorporated an independent telephone company at Belfield.

UNIONTOWN, WASH.—The Uniontown Telephone Company has been incorporated with a capital stock of $5,000.

BARTLEY, NEB.—The Bartley Mutual Telephone Company has been incorporated with a capital stock of $12,000.

LEBANON, WIS.—The Lebanon Telephone Company has been incorporated with a capital stock of $10,000.

CHISHOLM, MINN.—The Mesaba Telephone Company is about to move its exchange office at Chisholm into larger quarters. A larger board will be installed. C.

WILLMAR, MINN.—The Tri-State Telephone and Telegraph Company has secured larger quarters at Willmar and will install day and night operation of the toll service. C.

MARSHALLTOWN, IOWA—The Farmers and Merchants' Telephone Company of Marshalltown, Iowa, has been incorporated with a capital stock of $250,000. The officers are: B. F. Cummings, president; E. H. Martin, vice-president; P. C. Holdoegel, secretary; J. P. Cooper, treasurer. C.

LADORA, IOWA—The Farmers' Mutual Telephone Company of Ladora, Iowa, was incorporated with the following officers: W. L. Morse, president; Fred Guehrn, vice-president; M. W. Kelting, secretary; H. C. Gates, treasurer; E. H. Matteson, J. W. Bean and Geo. W. Rumple, directors. C.

CULBERTSON, MONT.—The Dakota Western Telephone Company of Culbertson has been incorporated by H. C. McCartney and T. F. Marshall of Oaks, N. D., and J. J. De Laney of Streeter, N. D. The company is capitalized for $200,000. The line will extend from Palermo, N. D., to Havre, Mont. C.

LA PORTE, IND.—The South Bend Home Telephone Company is asking the La Porte City Council for a franchise to permit it to install ten toll stations in La Porte. This action is due to the fact, as alleged, that the La Porte Telephone Company has refused to make arrangements with the South Bend Home Telephone Company for an exchange of service. S.

RICHMOND, IND.—The working agreement between the Central Union and the Richmond Home telephone companies, by which the long-distance service of the former was provided to patrons, has been discontinued. This action was taken on the Ohio court's order enjoining the Central Union from alleged interference with independent companies in Ohio and Indiana. As a result the Central Union can no longer give long distance service to the patrons of the Home company unless they go to the Central Union Company's office. S.

MINNEAPOLIS, MINN.—The attorney-general of Minnesota has given notice to the effect that the Northwestern Telephone Company cannot continue to sell reduced-rate telephone coupons without violating the laws of Minnesota. The company asked the attorney-general if the selling of coupons good for ten to twenty-five dollars' worth of talk at a reduction of ten to twenty-five per cent from the usual rate were lawful. Following the decisions of the United States Supreme Court and Interstate Commerce decisions, G. W. Peterson, who wrote the opinion, says that the sale of the coupons at a discount favors the man with $10 to invest in long-distance talk all at once and discriminates against others.

PERSONAL MENTION.

MR. G. W. ARMSTRONG, Chicago manager of the Excello Arc Lamp Company, is making an extended trip through the South, and writes from New Orleans that he is finding business in fine condition. The southern people are in prosperous shape, crops are good, and "Excello lamps are seen everywhere."

MR. BERNARD E. SUNNY, president of the Chicago Telephone Company and vice-president of the American Telephone and Telegraph Company, has been elected president of the Cleveland Memorial Association, the object of which is to erect a suitable monument to the memory of the late Grover Cleveland.

MR. JOHN C. DOLPH has retired from the Standard Varnish Works, New York city, and will engage in the same line in an independent connection. Mr. Dolph has spent the last twelve years in a study of insulating varnish processes, and has been very successful in establishing and building up the insulator department of the Standard Varnish Works.

"HURRY-UP" YOST, Michigan University's famous football coach, has been selected general manager of the Great Falls River and Power Company, chartered to develop the power of Great Falls and to build an electric short line from Chattanooga to Nashville. The Michigan leader is to take the place of the late C. H. Fisk, who died in McMinnville recently.

MR. R. C. CAMPBELL, district manager for the Philadelphia office of the Adams-Bagnall Electric Company, of Cleveland, Ohio, has recently returned from an inspection tour abroad and has opened new offices in the Land Title Building, Philadelphia, where any communications or inquiries concerning tungsten incandescent lamps, open or enclosed arcs, for operation under all conditions and on all circuits, or any problems involving the field of illuminating engineering, will receive his prompt attention.

EDUCATIONAL.

POLYTECHNIC INSTITUTE OF BROOKLYN—The Polytechnic Institute of Brooklyn, according to the annual report of its president, Fred W. Atkinson, has a total enrollment of 179 students, of whom fifty-six are in the department of electrical engineering. Professor Samuel Sheldon reports on the marked improvement attained in the electrical course and adds that new exercises are being arranged which will require more extended work on the part of the students.

UNIVERSITY OF ILLINOIS INSPECTION TRIP—The University of Illinois departments of electrical and railway electrical engineering visited Chicago November 21 for an inspection trip through a number of electrical manufacturing and power-generating plants of the city. The electrical engineering students made an extended visit to Croton Dam, Mich., visiting the hydroelectric generating station of the Grand Rapids-Muskegon Power Company's 110,000-volt transmission line into Grand Rapids.

NEW PUBLICATIONS.

LIST OF ELECTRICAL FITTINGS—The October list of electrical fittings that have been examined and approved by the Underwriters' National Electric Association for use under the rules and requirements of the National Board of Fire Underwriters for the installation of electric wiring and apparatus has been issued. This list is revised semi-annually.

THE WESTINGHOUSE DIARY FOR 1909—The 1909 edition of the Westinghouse Diary is ready for distribution. This is the fifth edition of the diary, and although this reference book has been of great value to engineers in previous years, the present edition is an improvement over anything that has been published before. The information in connection with high-pressure steam turbines, condensers, low-pressure steam turbines, mechanical stokers, mercury-vapor lamps, meter testing, storage batteries, single-phase railway systems, tungsten lamps, turbo pumps and blowers, and Westinghouse Nernst lamps, is particularly complete and of great value.

PROPOSALS.

POST OFFICE BUILDINGS AT PARIS, ILL., AND JOHNSON CITY, TENN.—The office of the Supervising Architect, Washington, D. C., will receive sealed proposals until January 6 for the construction (including plumbing, gas piping, heating apparatus, electric conduits and wiring) of the United States Post Offices at Paris, Ill., and Johnson City, Tenn., in accordance with specifications which may be obtained from the custodians of the sites, or at the office of the Supervising Architect.

ELECTRICAL SECURITIES.

Last week's developments in the stock markets showed confused and erratic trading and irregular price movements. Artificial manipulation was in evidence, and this included activity in low-priced issues. The financial community, however, holds to the belief that the larger interests are still committed to higher prices. The approach of the end of the year and the usual January reinvestment demand should bolster up public confidence, and it is expected that these events will make for better market conditions. There has been no noteworthy change in the slow improvement in industry in general. Comparisons now being made with last year's period of depression may be misleading, and for some time it is evident that reports of gross earnings should be analyzed very carefully.

Dividends have been declared upon the following electrical securities: Twin City Rapid Transit Company; regular quarterly dividend of one-and-three-fourths per cent on the preferred stock, payable January 2 to stock of record December 15. Butte Electric and Power Company; regular quarterly dividend of one-and-one-half per cent on the common stock, payable January 2 to stock of record December 20. Interborough Rapid Transit Company; regular quarterly dividend of two-and-one-fourth per cent on the capital stock of the company, payable January 2 to stock of record December 19. Chicago City Railway Company; regular quarterly dividend of one-and-one-half per cent, payable December 30 to stock of record December 8. United Traction and Electric Company; regular quarterly dividend of one-and-one-fourth per cent, payable January 2. Seattle Electric Company; a dividend of $2.75 a share on the common stock, payable January 15 to stock of record at the close of business January 1. Indianapolis Street Railway Company; a dividend of three per cent, payable January 1 to stock of record December 23. St. Joseph Railway, Light and Power Company; a quarterly dividend of one-and-one-fourth per cent on the preferred stock, payable January 1 to stock of record December 15. United Traction and Electric Company of New Jersey; quarterly dividend of one-and-one-fourth per cent, payable January 2. Wilkesbarre Gas and Electric Company; quarterly dividend of one per cent, payable January 2 to stock of record December 17.

ELECTRIC LIGHTING.

(Special Correspondence.)

PRESCOTT, WIS.—The Prescott Light and Power Company has been incorporated with a capital stock of $30,000.

HARRISON, N. J.—The Strang Electric Company has been incorporated in New Jersey with a capital stock of $25,000.

STEVENSVILLE, MONT.—G. W. Messer and Mr. Featherstone have applied for an electric-lighting franchise for Stevensville. C.

MURRAY, IOWA—A vote will be taken on December 15 at Murray on the question of granting a franchise to Mr. Murray for an electric-light plant. C.

GRIDLEY, CAL.—The City Clerk of Gridley is advertising for bids for furnishing and constructing an electric-lighting plant and distributing system for the city. A.

POSEYVILLE, IND.—The directors of the Poseyville Light and Power Company have decided to extend its transmission line to Cynthiana, a distance of fourteen miles. S.

SLATEDALE, PA.—The Slatedale Electric Light, Heat and Power Company is to be incorporated with a capital stock of $10,000. Wilson Rex is president of the company.

OLNEY, ILL.—The power plant of the Olney Electric Light and Power Company was completely destroyed by fire with a loss of $30,000, of which $17,000 was covered by insurance.

EVANSVILLE, IND.—Plans have been ordered by the Evansville Gas and Electric Light Company for the improvement and enlargement of its plant and the installation of some new equipment. S.

TWIN BRIDGES, MONT.—It is reported that Twin Bridges will be supplied with electric light from the power line which the Madison River Power Company will build from Renova to Sheridan. C.

SPRINGFIELD, ILL.—The Consumers' Electric Company, of Springfield, has been incorporated, with a capital stock of $1,000, to furnish light, heat and power. James A. Hull heads the company.

SANTA BARBARA, CAL.—The Water Commissioners of Santa Barbara have awarded to the Reynolds Electrical Company a contract for cable work and the installation of transformers amounting to $2,550. A.

NORCROSS, GA.—Norcross has voted for bonds, thirty to one, for electric lights. The Mayor and Council ordered the election for the purpose of voting upon the question of issuing bonds to the amount of $5,000.

WILMINGTON, DEL.—The Columbia Power, Light and Railways Company has been incorporated with a capital of $1,200,000 by W. H. Sprousler, Bloomfield, Pa.; M. P. Reed, Philadelphia, and C. L. Ward, Wilmington.

TIPTON, IND.—The Indiana Gas and Electric Light Company has applied for a franchise for a central plant, to be located at Tipton, agreeing to furnish both gas and electricity at a greatly reduced rate from that now charged. S.

RACINE, WIS.—Joseph Horlick, Jr., has undertaken the development of waterpower at the Rapids Dam, near Racine. He is under contract to furnish electricity for nearby plants and towns, and work is to be commenced immediately.

BOSTON, MASS.—The Gas Commission has approved of an issue of $15,000 additional stock by the Marion Gas Company, to be offered to stockholders at $100 per share, the proceeds to be used in the construction of an electric light and power plant.

CALISTOGA, CAL.—The plant, franchise and other property of the Calistoga Electric Light and Power Company at Calistoga has been sold under execution by the sheriff for the extremely small amount of $2,000. The buyer was William Spiers of Lakeport, Cal. A.

SABINAL, TEX.—The electric light and power company is now at work erecting poles and wires on the streets, and it is expected that the plant will be in operation within a few days. The company has been granted a franchise by the town for twenty years.

SAN JOSE, CAL.—R. W. Hersey of San Jose, promoter of the National Park Electric Company, and a party of engineers are now in Tuolumne County inspecting the site of the proposed plant. Mr. Hersey announces that work on the plant will be begun next spring. A.

LINTON, IND.—The City Council at its last meeting took steps to improve and increase the capacity of the electric-light plant. Those opposed to municipal ownership insist upon the sale of the plant, but the Council has decided otherwise and will improve the plant. S.

SAN FRANCISCO, CAL.—It is given out that a new electric power company to be known as the United States Electric Light and Power Company and to have an authorized capital stock of $40,000,000 will file articles of incorporation in San Francisco within a few days. A.

ESCANABA, MICH.—The Escanaba Power Company has been launched by O. L. Hule, formerly manager of the local traction company at Marinette, Wis., to construct a second power dam, capable of developing 2,500 horsepower, across the Escanaba River at Gross, Mich.

EUGENE, ORE.—The City Council of Eugene has decided on the construction of a power plant on the McKenzie River, about fifteen miles from the city. The power developed will be used chiefly for the operation of pumps for the recently-acquired water plant of the municipality. A.

ALBANY, N. Y.—The Central Station Operating Company, with a capital of $25,000, has been incorporated, to furnish gas and electric light in all the cities and villages in the state. The directors are William H. Sheehan, Edward F. McAviney and Frank L. Smith, of New York city.

ANDERSON, IND.—The Sefton Manufacturing Company of Anderson has decided to enlarge its local plant which, when completed, will cover nearly seven acres. The plant will be equipped with electric power throughout. Ex-Governor W. T. Durbin is vice-president and manager. S.

LOS ANGELES, CAL.—The San Joaquin Light and Power Company of Los Angeles, which has a plant under way on the Middle Tule River in Tulare County, is reported to have secured the site for its proposed dam on the Tule River by the purchase of the entire property on which the site was located. A.

AGNEWS, CAL.—The Board of Managers of the Agnews State Hospital at Agnews, Cal., is advertising for bids for the furnishing and erection of a power plant and conduit system to include boilers, engine, generators, switchboard, conduit pipe, wire and wiring. Bids will be received until December 16. A.

CAMAS, WASH.—Two applications for franchises for electric lighting have been presented to the Camas City Council. A steam plant is proposed by Kelley Loe, who applied for a fifty-year franchise, while G. S. Smith of Washougal contemplates building a system to supply both towns with power from the Washougal River.

CHICAGO, ILL.—It has been definitely announced that the Commonwealth Edison Company has acquired the property and franchises of the Cosmopolitan Electric Company. The latter was recently granted a building permit for a power house costing $280,000, to replace its present plant at Canal and Grove streets and the south branch of the Chicago River.

PORTLAND, ORE.—F. S. Morris, of Morris Bros., Portland, has begun preliminary work for the construction of a power plant on the Clackamas River, near Portland. It is given out that the plant will have a capacity of 15,000 horsepower and will cost in the neighborhood of $500,000. The work includes the building of a dam 400 feet long and forty feet high. A.

SEATTLE, WASH.—The Pacific Coast Light and Power Company of Seattle, Wash., has begun condemnation proceedings for the purpose of securing water rights on White River which are supposed to be the property of the Muckleshoot Indians. The company plans to convey water from White River to a point on Stuck River, where the power house will be located. A.

TACOMA, WASH.—The City Council of Tacoma has called an election for December 16 to vote on the question of the construction of a municipal electric power and lighting plant of 20,000 horsepower on the Upper Nisqually River at a cost of about $2,000,000. On the same date the issue of bonds to the amount of $300,000 for the preliminary expenses for rights, etc., will be voted on. A.

EASTON, PA.—The Easton Gas and Electric Company has a project on foot that is bound to result in benefit to the city and community. By the erection of a sign the name and location of Easton is to be burned into the minds of travelers on the various railroads passing through the city. The people of the city are asked to do their share, and a slogan is to be selected and suggested by the people.

BELLINGHAM, WASH.—Howard E. Grant, manager at Bellingham, Wash., for Stone & Webster of Boston, announces that it has been decided to double the capacity of the power plant on the Nooksaak River, controlled by Stone & Webster, the cost of the improvement to be about $250,000. When the changes are completed the power plant will be made the distributing point for the company's interurban railway lines. A.

PORTLAND, ORE.—President Josselyn, of the Portland Railway, Light and Power Company, has approved of the order for underground conduits for the company's system in the business section of the city. Work will commence at once. When completed it will cost in the neighborhood of $1,250,000. Orders have also been given for the installation of new machinery at the Alder and Seventh streets substation at a cost of $150,000. A.

JOLIET, ILL.—The Illinois Steel Company has entered into a contract with the Sanitary District of Chicago to use 1,200 horsepower of electrical energy from the latter's hydroelectric plant at Lockport, Ill. A special transmission line about three miles long will be built from this plant to the steel works. This will be fed directly from the generator buses at 6,600 volts and will be distinct from the 45,000-volt transmission line to Chicago.

LA CROSSE, WIS.—Governor Johnson of Minnesota and Governor Davidson of Wisconsin have been invited to attend the ceremonies marking the formal opening of the works of the La Crosse Water Power Company about December 15. The dam is 50 feet high, 50 feet wide at the base and 495 feet long, damming the Black River into a reservoir lake in its rear. This lake is five-and-one-half miles long and in some places two-and-one-half miles wide. When the water is over the dam there is a storage reserve of 479,160,000 cubic feet.

LEXINGTON, N. C.—The Fries Power Company has closed a contract with the Southern Power Company, the great water-power concern below Charlotte, on the Catawba, whereby this company will enter Winston and furnish 1,500 horsepower of electricity. The transmission lines will be built through Lexington, High Point and Greensboro, these towns, including Thomasville, having the opportunity of securing electric power, also. The Southern Power Company has already built lines and is furnishing power to Charlotte, Mooresville, Statesville, Newton and various other communities.

MERRILL, WIS.—Current has been turned on from the recently completed hydroelectric power plant at Grandfather Falls. The dam is 700 feet long and 70 feet in height. At the right end is the power house, which is 44 feet square and 23 feet high. In this is installed one 1,400-kilowatt generator with its exciter. Other flumes have been constructed to receive additional units to the amount of 3,700 kilowatts when necessary. The power is transmitted twelve miles to the city over high-tension transmission wires, and is used at the mills of the Grandfather Falls, and for lighting purposes at Grandfather.

NORTH YAKIMA, WASH.—Another big electric-power project, where 4,000 to 5,000 horsepower can be developed from the Naches River flow, is planned for the vicinity of North Yakima. Local capitalists have already procured a site for a new power house and the right-of-way for the canal to it, assuring a drop of sixty feet to the power wheel. The power estimated is at the lowest stage of the river. There are now four big power projects under construction near North Yakima, that of the Northwest Light and Power Company, the Yakima Valley Transportation Company's canal through the Moxee to Union Gap, and the East Selah project in the Yakima River Canyon, besides the new one.

OAKLAND, CAL.—The Great Western Power Company of San Francisco has completed the installation of the first unit of its power plant on the Feather River as well as the cementing of the three-and-one-half-mile tunnel which will convey water to the power house. December 10 was set as the date for starting the plant. The initial production will be 20,000 horsepower of electric energy. It is expected that the company's transmission line to Oakland on San Francisco Bay will be completed about that time. The company has filed deeds for a right-of-way through the lands of the People's Water Company in Alameda County, Cal., and will erect its line over the property at once. A.

COLORADO SPRINGS, COLO.—The controlling interest in the Empire Water and Power Company was recently sold to George Bullock, of New York, president of the Colorado Springs Electric Company. Mr. Bullock announced that development to the extent of $500,000 will be prosecuted within the next twelve months. The company owns valuable water rights on the north slope of Pike's Peak and has plans already made for the building of three large reservoirs with necessary pipe lines and an electric power plant in Manitou that will develop 3,000 horsepower, which will be used in supplying power to the large mills and other manufacturing concerns in the Pike's Peak region.

SALT LAKE CITY, UTAH—The application for water power for the largest electric producing plant in Utah has been filed with the state engineer by the Grand Canyon Power Company, Incorporated. The company asks for 2,000 feet of water per second from the Green River, which will be used in running a plant capable of producing 38,000 horsepower. The fees paid for the water rights are $2,000. The plan of the company is to place an immense dam in the Green River 200 feet below its junction with the Coal Creek in Emery County. This will back the water up in Green River for twenty miles. Near the junction of Coal Creek with Green River a diverting channel will be constructed. It will be twenty-four feet wide, ten feet deep and 9,000 feet long.

BELLOWS FALLS, VT.—The Cavendish Gorge hydroelectric generating plant of the Claremont Electric Company is now practically in commission and supplying electricity for a variety of purposes. The dam is of concrete, fifty-four feet high and 107 feet wide along the crest or rollway. The thickness below the water line is thirty-eight feet. There are two gates and a forty-eight-inch waste-water pipe. The gate leading into the fore-bay is nineteen feet below water surface. From the forebay an eight-foot tunnel extends through 200 feet of rock, connecting with a steel penstock six feet in diameter and 1,100 feet long, that conveys the water to the turbines in the power house. In the brick and concrete power house are three Pelton wheels, direct-connected to an equal number of Fort Wayne generators of 500 kilowatts capacity.

SAN FRANCISCO, CAL.—Several large appropriations of water for electric power purposes in California have been made during the last few days. Most of these are in the northern part of California. Among these are: The appropriation of 300,000 inches from the Sacramento River at Tron Canyon by Paul Stoll; the appropriation of 8,000 inches from Deer Creek, near Chico, by William Elliott; 11,000 inches from Battle Creek by H. A. Tedford and W. W. Wheeler. In central California, J. W. McLaughlin and C. K. Kirby have appropriated 300,000 inches of water from the San Joaquin River to be diverted in Fresno County. The Mountain Development Company of Tacoma, Wash., has appropriated 2,000 cubic feet of water from the south bank of White River, near Tacoma, to be stored and used for electric power purposes. The latter company has just been incorporated with a capital stock of $200,000 by B. P. Simonds, Robert M. Davis and A. J. Firmin. A.

ELECTRIC RAILWAYS.

(Special Correspondence.)

MISSOULA, MONT.—W. A. Clark and others have been granted a fifty-year franchise for an electric line. P.

GRAND FORKS, N. D.—The Grand Forks Street Railway Company is to be incorporated with a capital of $150,000. P.

GRUNDY CENTER, IOWA—A right-of-way has been granted at Grundy Center to the proposed electric road from Waterloo to Perry. C.

SIOUX CITY, IOWA—The Sioux City and Spirit Lake Interurban has petitioned for franchises in Spirit Lake, Hartley and Le Mars, Iowa. C.

BUXTON, IOWA—An interurban railway is projected by Byllesby & Company of Chicago, from Ottumwa to Buxton, passing through Eddyville. C.

JACKSON, MINN.—It is proposed to build an electric line from Jackson to Spirit Lake, Iowa, to connect the Sioux City and Spirit Lake road with the Dan Patch Air Line. C.

ELGIN, ILL.—The De Kalb Midland Railway Company has been formed to construct and operate an electric railway from De Kalb to Sandwich, Ill. The capital stock is $150,000 and the incorporators are John W. McQueen, Herbert J. Burdick and John F. Pearce.

L'ANSE, MICH.—The new hydroelectric power plant at L'Anse has been started successfully. This generating station is one of the few waterpower plants in the northern peninsula of Michigan and was constructed after a new steam plant had already been built and discarded.

BERNE, IND.—The stockholders of the Bluffton, Berne & Celina Company, recently organized to construct a traction line between the cities above named, will file articles of incorporation during the coming week. Bids will be received in a short time for the construction of the road. S.

SAN FRANCISCO, CAL.—The delay in the return of President Patrick Calhoun of the United Railroads of San Francisco to California has led to a number of rumors of a possible sale of the company to E. H. Harriman or to interests allied with Mr. Harriman. All knowledge of such a move is denied by the company's representatives here. A.

GARY, IND.—The construction of a street railway connecting the cities of Whiting, Indiana Harbor and Gary is the object of the franchise now being asked of the City Council of East Chicago. The capitalist behind the project is Louis N. Erb, of Chicago, who with other Chicago capitalists recently procured a franchise to enter the city of Whiting. S.

CHICAGO, ILL.—Receivers J. B. Forgan and John M. Roach of the Consolidated Traction Company were given leave of court on December 2 to borrow $200,000 for use in rehabilitation work on the Cicero & Proviso branch of the Consolidated lines. The receivers were authorized to pledge the receipts of the road until 1910 as security for the money to be borrowed.

INDIANAPOLIS, IND.—J. W. Wood of Evansville, senior member of the Indiana Railroad Commission, who has been elected chairman of the Commission, just returned from a meeting of railroad commissioners held in Chicago and reports that the commissioners from Illinois, Michigan and Minnesota decided to adopt the Indiana plan of separating grade crossings of railroads. S.

SOUTH BEND, IND.—The Chicago, Lake Shore & South Bend, the traction line between South Bend and Chicago, which is now in operation between South Bend and South Chicago, has been officially changed in name to the South Shore Line. The company has ten cars in operation between South Bend and Hammond, eleven to Michigan City and twenty-nine to Hammond and Gary. S.

SOUTH BEND, IND.—Under the authority of the board of public works, the South Bend police stopped the Chicago, South Bend & Northern Indiana Traction Company from stretching an overhead feed-wire in the business district of the city. The wire was being stretched on the trolley poles in violation of an ordinance providing that all wires in the business district must be placed underground. The board has also instructed the city attorney to bring proceedings against any person or corporation violating any provision of the ordinance governing wires in the underground district. S.

DETROIT, MICH.—The franchise of the new Windsor Tunnel & Lake Erie Electric Railway Company is now before the City Council of Detroit. The company has agreed to issue workingmen's tickets at eight for a quarter during four hours of the day, with five-cent fares at all other times. The promoters of the road will apply immediately to the Government for a charter of incorporation.

GOSHEN, IND.—Harry L. Weber, consulting engineer in the employ of the Ohio & Indiana Traction Company, and an expert in interurban railway engineering, with a company of assistants, arrived to survey a line between Goshen and Kendallville. Mr. Weber comes in the interest of Boston capitalists, who are proposing to construct the line which is supposed to be the beginning of an interurban line from Chicago to New York. S.

INDIANAPOLIS, IND.—A contract for the construction of a $4,700,000 interurban traction line to connect the cities of Des Moines and Sioux City, Iowa, has been awarded to the American Engineering Company of Indianapolis. The line will be about 196 miles long and will be a part of the triangular system that is being constructed to connect Des Moines, Sioux City, Omaha and Council Bluffs. Chas. N. Wilson, president of the construction company, says that the line will ultimately be a connecting link between Ohio, Indiana and the West. S.

TERRE HAUTE, IND.—The United States Express Company has opened offices in Terre Haute to operate over the four branches of the Terre Haute, Indianapolis & Eastern Traction Company, to Paris, Ill., Sullivan, Clinton and Indianapolis and eastward. The traction company has been doing a semi-express business in connection with its freight business, but did not collect or deliver packages as will now be done by the United States company. It is understood that the deal covers all the lines of what is known as the McGowan syndicate. S.

SAN FRANCISCO, CAL.—Charles N. Black, vice-president and general manager of the United Railroads of San Francisco, announces that eight carloads of power machinery are now due in the city. This will be installed at once and will go far to repair the company's system and put it in shape to resume a full service on its lines. A recent accident to a 6,000-horsepower frequency-changer did considerable damage to the system, rendering it unable to handle some of the power which it had been taking from the City Electric Company. Some of the machinery rented from the Pacific Gas and Improvement Company has also been out of order, but it is expected that this will soon be remedied. A.

SAN FRANCISCO, CAL.—Vice-President and General Manager E. E. Calvin, of the Southern Pacific Company, denies specifically the report that the company has secured control of the Great Western Power Company or of any other power company. He says: "The Southern Pacific Company has bought no power company and owns no sites of its own in the Sierras. We are not planning to operate our suburban trains by hydroelectric plants, but are going ahead with our steam power plant in Oakland. We have cheap oil of our own for use in developing power and do not anticipate that any of the power companies with hydroelectric plants will be able to supply us with power cheaper than we will be able to generate it in our Oakland plant. If any company offers to do so we shall accept the offer and hold our Oakland plant as a reserve plant. A considerable part of the machinery for our Oakland plant is already on the way and more is being manufactured. The trolley wire and feed wire is already on hand. The suburban railway lines in Alameda, Berkeley and Oakland will be converted into trolley lines at once in the order named. The line south from San Francisco will be a third-rail line. The matter of using electricity for the operation of our transcontinental lines over the Sierra Nevada Mountains is for the distant future." A.

INDUSTRIAL ITEMS.

THE SOUTHERN ELECTRICAL AND INDUSTRIAL EXPOSITION has been incorporated at Louisville, Ky. The officers are: F. W. Keisker, president; J. V. Beckmann and F. C. Nunemacher, vice-presidents, and A. T. Macdonald, secretary.

THE METROPOLITAN ELECTRICAL SUPPLY COMPANY, 184 Lake Street, Chicago, Ill., has ready for distribution some interesting information in booklet and pamphlet form concerning Christmas-tree outfits. This literature will be sent to those interested upon request.

THE BRILL CAR WORKS, Philadelphia, Pa., suffered damage by conflagration on Sunday, November 29, variously estimated from $100,000 to $250,000, pending the company's official estimate of the loss. It is believed that the damage will not interfere seriously with any of the company's contracts.

THE CHICAGO MICA COMPANY, Valparaiso, Ind., announces that Judge Anderson, in the United States Circuit Court, District of Indiana, on December 4, at Indianapolis, refused the plea of the Mica Insulator Company for a temporary injunction to enjoin the Chicago Mica Company from manufacturing mica insulating plates.

THE STEEL ROLL MACHINE COMPANY, 254 East Madison Street, Chicago, manufacturer of laundry equipment, calls attention to the waste involved in throwing away soiled printers' cleaning rags, which, it advises, should be washed in a power washing machine of its manufacture. The rags are washed and rinsed thoroughly without attention.

THE H. T. PAISTE COMPANY, Philadelphia, Pa., devotes the November issue of its monthly house organ *Paistery* to describing and illustrating its National Electrical Code standard pipe taplets adapted for a variety of uses. The pipe taplet is attached to the conduit by pipe threads, located inside the sleeve. A set-screw method of adjustment enables the work to be lined up perfectly.

THE WESTERN ELECTRIC COMPANY, Chicago, in a little booklet entitled "Pointers on Power" describes in an attractive way a number of the applications of its line of alternating-current induction motors. The variety of uses illustrated includes the employment of these motors in driving centrifugal pumps, sheet-metal machinery, turn-table tractors, conveyers, dough mixers, wood-working machinery and exhaust fans.

THE GENERAL ELECTRIC COMPANY, Schenectady, N. Y., in bulletin No. 4627, describes its curve-drawing instruments for alternating and direct-current circuits. These instruments, though in commercial use for several years, have been recently improved by the General Electric Company, and the illustrations and descriptions contained in the bulletin are of interest. The bulletin contains, also, connections, dimensions and other data.

THE GREGORY ELECTRIC COMPANY, Chicago, dealer in electrical apparatus and machinery, has issued a new bargain sheet showing its complete stock. The company is offering exceptional bargains in alternating-current motors, which will doubtless prove attractive to a great many possible buyers. The company is well equipped for the buying and selling of second-hand machinery and is one of the largest dealers in this line. It will be glad to send its latest bargain sheet to interested parties.

THE ELECTRIC MOTOR AND EQUIPMENT COMPANY, Newark, N. J., announces that it has succeeded to the business of the American Chemical Company, formerly conducted by H. C. Swann at 79 Cortlandt Street, New York city. The latter company manufactured the well-known "Faultless" lamp coloring and "Faultless" weatherproof lamp coloring. These colorings, which have been in the market for eight years, are furnished in eighteen colors and shades, or any desired blend to order.

THE CENTRAL ELECTRIC COMPANY, Chicago, Ill., is distributing a new line of circulars especially devoted to articles intended for holiday gifts, such as electric-heating devices, Christmas-tree outfits, electric curling-irons, etc. A new folder describes the "Never Break" electric lamp guards and approved electrical fittings. This circular consists of forty pages of descriptive matter, supplemented by interesting information taken from the reports of the Electrical Bureau and National Board of Fire Underwriters. Copies will be sent upon request.

THE GAS CANNON COMPANY, South Bethlehem, Pa., is distributing an interesting circular calling attention to the flintlock model of the gas cannon. This cannon works on the principle of the ordinary gas engine. Gas is allowed to flow into the gun and mix with the air. The mixture is ignited, producing an absolutely harmless explosion. The cork or wooden projectile is not dangerous, and a heavy metal projectile cannot be thrown by the gun at all. There is no other element of danger, because the tongue of flame from the gun will not set fire even to tissue paper or burn the skin.

THE HOYT ELECTRICAL INSTRUMENT WORKS, Penacook, N. H., announces that it has opened an office at 161 Summer Street, Boston, Mass., to take care of its New England trade. The demand for Hoyt instruments from New England centers has shown such a steady and consistent increase since they were first offered a year ago that it was felt the interests of the company's patrons could best be served in this way. The office will be in charge of H. F. Kellogg, a pioneer in the electrical field, and well known in automobile circles. A complete stock of instruments will be carried at all times.

THE CARLYLE-JOHNSON MACHINE COMPANY, Hartford, Conn., has a new catalogue descriptive of the Johnson friction clutch. This clutch has but few parts and is very compact. A body fastened to the shaft carries a split ring in which are inserted a pair of levers. A curve-shaped wedge, which is made part of a shipper sleeve, forces the levers apart, expanding the ring, bringing its outer surface into frictional contact with the inner surface of the friction cup, the hub of which is made to suit requirements. The leverage is so compounded that it requires but little pressure to operate the clutch.

THE HARVARD ELECTRIC COMPANY, 66 West Van Buren Street, Chicago, and 136 Liberty Street, New York, manufacturer of steel brackets, conduit boxes, sectional switch boxes, fuse wire, electrical specialties, etc., announces that since recovering from the August fire which nearly destroyed the Harvard plant, the factory has been working overtime, the total of the October orders being greater than those of any two months during the 1908 season. Allen L. Haase, sales manager of the company, recently returned from a trip through the South and reports exceptionally bright prospects in all the cities he visited.

THE MINNEAPOLIS ELECTRIC AND CONSTRUCTION COMPANY of Minneapolis, Minn., which, for a number of years, has placed on the market a wire-measuring machine which reels wire into a coil and shows the number of feet, is meeting with excellent success. This reel, the manufacturer states, is now used in almost every state in the Union. The company recently received an order from the United States Government for an electric wire meter to be used for measuring signal wire in the Navy Yard, Seattle, Wash. The same device is also used by the United States Government in Manila. The Otis Elevator Company, Minneapolis, made a test on one of the company's large size meters, measuring seven-eighths-inch steel cable, which proved very satisfactory.

C. H. CHALMERS, vice-president of the Electric Machinery Company, Minneapolis, reports a satisfactory business and states that the outlook for the coming year is encouraging. The company has recently booked a number of new orders, among them being one from the Acme Cement Plaster Company, Acme, Texas, secured through the Wesco Supply Company of St. Louis, for one 180-kilowatt revolving-field alternator. The Electric Machinery Company is also installing two 300-kilowatt machines for the Peerless Electric Company, Warren, O., making four machines in all. Two seventy-five-kilowatt engine-type generators, one thirty-kilowatt motor-driven and one twenty-kilowatt balancing sets are being shipped to the Southern Pacific Railway at San Francisco. This order was secured through the company's Pacific agents, the Standard Electrical Works.

THE PETTINGELL-ANDREWS COMPANY, Boston, for December presents the first issue of its new house organ, entitled "Juice." Between striking covers are well-printed pages describing and illustrating "O. K." connection blocks, "Opalux" reflectors, "P-M" remote-control switches, "New Wrinkle" sockets, and other specialties. The leading article, relative to devices designed to prevent the theft of current from unauthorized taps outside the meter, is accompanied by thirty views and diagrams of connection blocks, showing the variety of connections that can be made with these blocks for purposes of applying test instruments, without interrupting the continuity of the consumer's service. "Juice" wil be regularly mailed to central stations, street railways, electrical engineers, architects, contractors, dealers and isolated manufacturing plants using electricity.

THE WHEELER CONDENSER AND ENGINEERING COMPANY, Carteret, N. J., has just published "The Wheeler-Edwards Air Pump," an elaborate thirty-two-page treatise which explains the peculiar action of the Wheeler-Edwards pump in handling both air and water. It is shown how the absence of foot and bucket valves, and an exceedingly small clearance, results in the attainment of a high vacuum, otherwise to be had only by means of separate dry vacuum pumps, hot well pumps and air coolers. Various types of Wheeler-Edwards pumps are shown, as well as a number of large steam-turbine installations in which these pumps are used. The latter half of the book is made up of the discussions of the principles of air pumps, tables of mixed vapors, a complete and original table of saturated water vapor from 60 to 180 degrees F., etc. The final section gives practical instructions for the handling of pumps of this character. This booklet should be valuable to anyone interested in vacuum machinery.

NEW MANUFACTURING COMPANIES.

DULUTH, MINN.—The Duluth Electrical Company of Duluth, with a capital stock of $25,000, has been incorporated by J. W. Day, M. J. Day and H. J. Rich. C.

BROOKLYN, N. Y.—The Bell Arc Light Company, of Brooklyn, has been organized with a capital of $100,000. The directors are: Charles A. Campbell, Henry W. Van Allen and Monroe May, all of New York.

SCHENECTADY, N. Y.—The Tirrill Manufacturing Company has been incorporated with a capital stock of $100,000, to manufacture electrical appliances and machinery. The members of the company are Allen A. Tirrill, Everett E. Lucas, Franklin W. McClellan, Schenectady.

NEW YORK, N. Y.—The Jaeger Tungsten Company of Manhattan has been incorporated to manufacture Tungsten lamps, electrical and illuminating appliances, etc., with a capital of $30,000. The incorporators are W. C. Lillehold, Brooklyn; C. S. Pinkney, H. J. Robinson and J. Wilzing, New York city.

ENGINEERING SOCIETIES.

ARMOUR INSTITUTE BRANCH, A. I. E. E.—At the meeting of the Armour Institute Branch, American Institute of Electrical Engineers, held in Chapin Hall on December 3, an interesting paper on "Alternating-Current Single-Phase Commutator Motors" was presented by Tracy W. Simpson. All the commercial forms of these motors were analyzed and their characteristics pointed out. On January 7, 1909, Arthur P. Strong will present a paper on "Economic Considerations in the Design of Multi-Office Trunk Telephone Systems;" this paper was originally announced for December 17, but was postponed to the first meeting in 1909 on account of conflict with Dr. Steinmetz's lecture to be given on that date.

Directory of Electrical and Allied Engineering and Scientific Societies.

(Published in the Second Issue of Each Month.)

AMERICAN ASSOCIATION OF ELECTRIC MOTOR MANUFACTURERS. Secretary, W. H. Tapley, Walker Electric Company, Twenty-third and Noble streets, Philadelphia, Pa. Next meeting, January, 1909.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE. Secretary, L. O. Howard, Cosmos Club, Washington, D. C. Annual meeting, Baltimore, Md., December 28-January 2.

AMERICAN ELECTROCHEMICAL SOCIETY. Secretary, Dr. J. W. Richards, Bethlehem, Pa.

AMERICAN ELECTROTHERAPEUTIC ASSOCIATION. Secretary, Dr. Albert C. Geyser, 352 Willis Avenue, New York, N. Y.

AMERICAN FOUNDRYMEN'S ASSOCIATION. Secretary, Dr. Richard Moldenke, Watchung, N. J.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS. Secretary, Ralph W. Pope, Engineering Societies Building, 29 West Thirty-ninth Street, New York, N. Y.

AMERICAN INSTITUTE OF MINING ENGINEERS. Secretary, Rossiter W. Raymond, 29 West Thirty-ninth Street, New York, N. Y.

AMERICAN MATHEMATICAL SOCIETY. Secretary, F. N. Cole, 50 West 116th Street, New York, N. Y.

AMERICAN RAILWAY MASTER MECHANICS' ASSOCIATION. Secretary, J. W. Taylor, Old Colony Building, Chicago, Ill.

AMERICAN ROENTGEN-RAY SOCIETY. Secretary, Dr. G. C. Johnson, 514 Bijou Building, Pittsburg, Pa. Annual meeting, New York, N. Y., December 28-30.

AMERICAN SOCIETY FOR TESTING MATERIALS. Secretary, Prof. Edgar Marburg, University of Pennsylvania, Philadelphia, Pa.

AMERICAN SOCIETY OF CIVIL ENGINEERS. Secretary, Charles Warren Hunt, 220 West Forty-seventh Street, New York, N. Y.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Secretary, Calvin W. Rice, 29 West Thirty-ninth Street, New York, N. Y.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS. Secretary, A. P. Folwell, 239 West Thirty-ninth Street, New York, N. Y.

AMERICAN STREET AND INTERURBAN RAILWAY ASSOCIATION. Secretary, B. V. Swenson, Engineering Societies Building, 29 West Thirty-ninth Street, New York, N. Y.

AMERICAN STREET AND INTERURBAN RAILWAY ACCOUNTANTS' ASSOCIATION. Secretary, H. E. Weeks, secretary and treasurer Tri-City Railway Company, Davenport, Iowa.

AMERICAN STREET AND INTERURBAN RAILWAY CLAIM AGENTS' ASSOCIATION. Secretary, B. B. Davis, claim agent Columbus Railway and Light Company, Columbus, Ohio.

AMERICAN STREET AND INTERURBAN RAILWAY ENGINEERING ASSOCIATION. Secretary, J. W. Corning, electrical engineer Boston Elevated Railway Company, Boston, Mass.

AMERICAN STREET AND INTERURBAN RAILWAY TRANSPORTATION AND TRAFFIC ASSOCIATION.

AMERICAN STREET AND INTERURBAN RAILWAY MANUFACTURERS' ASSOCIATION. Secretary, George B. Keegan, 2321 Park Row Building, New York, N. Y.

ARKANSAS ASSOCIATION OF PUBLIC UTILITY OPERATORS. Secretary, J. E. Cowles, superintendent of lighting Hot Springs Light and Railway Company, Hot Springs, Ark.

ARKANSAS INDEPENDENT TELEPHONE ASSOCIATION. Secretary, Charles F. Speed, Texarkana, Ark.

ASSOCIATION OF CAR-LIGHTING ENGINEERS. Secretary, G. B. Colegrove, Illinois Central Railroad, Chicago, Ill.

ASSOCIATION OF EDISON ILLUMINATING COMPANIES. Secretary, D. L. Huntington, second vice-president and manager Washington Water Power Company, Spokane, Wash.

ASSOCIATION OF ELECTRIC LIGHTING ENGINEERS OF NEW ENGLAND. Secretary, Welles E. Holmes, 308 Washington Street, Newton, Mass.

ASSOCIATION OF RAILWAY TELEGRAPH SUPERINTENDENTS. Secretary, P. W. Drew, Wisconsin Central Railway, Milwaukee, Wis.

CALIFORNIA ELECTRIC RAILWAY ASSOCIATION. Secretary, L. E. W. Pioda, Oak and Broderick Streets, San Francisco, Cal.

CALIFORNIA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, P. T. Whittier, Spencer, Cal.

CANADIAN ELECTRICAL ASSOCIATION. Secretary, T. S. Young, Toronto, Canada.

CANADIAN STREET RAILWAY ASSOCIATION. Secretary, Acton Burrows, 33 Melinda Street, Toronto, Ontario.

CENTRAL ELECTRIC RAILWAY ASSOCIATION. Secretary, A. L. Neereamer, Traction Terminal Building, Indianapolis, Ind.

COLORADO ELECTRIC LIGHT, POWER AND RAILWAY ASSOCIATION. Secretary, J. C. Lawler, Colorado Springs, Colo.

CONNECTICUT STATE STREET RAILWAY ASSOCIATION. Secretary, F. W. Poole, Bridgeport, Conn.

ELECTRICAL CONTRACTORS' ASSOCIATION OF NEW YORK STATE. Secretary, George William Russell, Jr., 500 Fifth Avenue, New York, N. Y.

ELECTRICAL CONTRACTORS' ASSOCIATION OF STATE OF MISSOURI. Secretary, Charles J. Sutter, 1220 Pine Street, St. Louis, Mo.

ELECTRICAL TRADES ASSOCIATION OF CHICAGO. Secretary, Frederick P. Vose, Marquette Building, Chicago, Ill.

ELECTRICAL TRADES ASSOCIATION OF PHILADELPHIA. Secretary, E. A. Symmes, 810 Drexel Building, Philadelphia, Pa. Meetings, second and fourth Thursdays of each month.

ELECTRICAL TRADES ASSOCIATION OF CANADA, LIMITED. Secretary, William R. Stanley, Royal Insurance Building, Montreal, Canada.

ELECTRICAL TRADES ASSOCIATION OF THE PACIFIC COAST. Secretary, Albert H. Elliott, Claus Spreckels Building, San Francisco, Cal. Monthly meetings, San Francisco, Cal., first Thursday of each month.

ELECTRICAL TRADES SOCIETY OF NEW YORK (Member National Electrical Trades Association). Secretary, Franz Neilson, 80 Wall Street, New York, N. Y. Board of directors meets second Friday of each month.

EMPIRE STATE GAS AND ELECTRIC ASSOCIATION. Secretary, Charles H. B. Chapin, 154 Nassau Street, New York, N. Y.

ENGINEERS' CLUB OF PHILADELPHIA. Secretary H. G. Perring, 1317 Spruce Street, Philadelphia, Pa.

ENGINE BUILDERS' ASSOCIATION OF THE UNITED STATES. Secretary, J. I. Lyle, 39 Cortlandt Street, New York, N. Y.

ILLINOIS INDEPENDENT TELEPHONE ASSOCIATION. Secretary, C. A. Camp, Henry, Ill.

ILLINOIS STATE ELECTRICAL ASSOCIATION. Secretary, H. E. Chubbuck, La Salle, Ill.

ILLUMINATING ENGINEERING SOCIETY. Secretary, Van Rensselaer Lansingh, Engineering Societies Building, 33 West Thirty-ninth Street, New York, N. Y.

INDEPENDENT TELEPHONE ASSOCIATION OF TEXAS AND LOUISIANA. Secretary, C. A. Shock, Sherman, Tex.

INDIANA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, Allen J. Paylow, Rockport, Ind.

INTERNATIONAL ASSOCIATION OF MUNICIPAL ELECTRICIANS. Secretary, Frank P. Foster, Corning, N. Y.

INTERNATIONAL INDEPENDENT TELEPHONE ASSOCIATION. Secretary, J. B. Ward, Grand Rapids, Mich. Secretary's office, Monadnock Building, Chicago, Ill.

IOWA ELECTRICAL ASSOCIATION. Secretary, W. N. Keiser, Des Moines, Iowa.

IOWA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, C. C. Deering, Boone, Iowa.

IOWA STREET AND INTERURBAN RAILWAY ASSOCIATION. Secretary, L. D. Mathes, Dubuque, Iowa.

KANSAS GAS, WATER, ELECTRIC LIGHT AND STREET RAILWAY ASSOCIATION. Secretary, James D. Nicholson, Newton, Kan.

KENTUCKY INDEPENDENT TELEPHONE ASSOCIATION. Secretary, W. G. Turpine, Henderson, Ky.

MAINE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, M. E. Crow, Houlton, Me.

MAINE STREET RAILWAY ASSOCIATION. Secretary, E. A. Newman, 471 Congress Street, Portland, Me.

MASSACHUSETTS STREET RAILWAY ASSOCIATION. Secretary, Charles S. Clark, 70 Kilby Street, Boston, Mass. Meets second Wednesday of each month, except July and August.

MASTER CAR BUILDERS' ASSOCIATION. Secretary, J. W. Taylor, 390 Old Colony Building, Chicago, Ill.

MICHIGAN ELECTRIC ASSOCIATION. Secretary, A. C. Marshall, Port Huron, Mich.

MICHIGAN INDEPENDENT TELEPHONE ASSOCIATION. Secretary, A. A. Burch, Battle Creek, Mich.

MILWAUKEE SOCIETY OF ENGINEERS. Secretary, W. Fay Martin, 456 Broadway, Milwaukee, Wis.

MISSOURI ELECTRIC LIGHT, GAS AND STREET RAILWAY ASSOCIATION. Secretary, Claude L. Clary, Sikeston Electric Light and Power Company, Sikeston, Mo.

MISSOURI INDEPENDENT TELEPHONE ASSOCIATION. Secretary, George W. Schweer, Windsor, Mo.

NATIONAL ARM, PIN AND BRACKET ASSOCIATION. Secretary, J. B. Magers, Madison, Ind.

NATIONAL ELECTRICAL CONTRACTORS' ASSOCIATION OF THE UNITED STATES. Secretary, W. H. Morton, 41 Martin Building, Utica, N. Y.

NATIONAL ELECTRICAL TRADES ASSOCIATION. Secretary, Frederic P. Vose, 1343 Marquette Building, Chicago, Ill.

NATIONAL ELECTRIC LIGHT ASSOCIATION. Secretary, John F. Gilchrist, Commonwealth Edison Company, Chicago, Ill.

NEBRASKA ELECTRICAL ASSOCIATION. Secretary, William Bradford, Lincoln, Neb.

NEBRASKA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, R. E. Mattison, Lincoln, Neb.

NEW ENGLAND ELECTRICAL TRADES ASSOCIATION. Secretary, Alton F. Tupper, 60 State Street, Boston, Mass.

NEW ENGLAND STREET RAILWAY CLUB. Secretary, John J. Lane, 12 Pearl Street, Boston, Mass. Meetings held on fourth Thursday of each month.

NEW YORK ELECTRICAL SOCIETY. Secretary, G. H. Guy, Engineering Societies Building, 29 West Thirty-ninth Street, New York, N. Y.

NEW YORK STATE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, R. Max Eaton, Niagara Falls, N. Y.

NORTHWEST ELECTRIC LIGHT AND POWER ASSOCIATION. Temporary secretary, J. D. Crary, Aberdeen, Wash.

NORTHWESTERN ELECTRICAL ASSOCIATION. Secretary, R. M. Kimball, Kenosha, Wis. Annual meeting, Milwaukee, Wis., January, 1909.

OHIO ELECTRIC LIGHT ASSOCIATION. Secretary, D. L. Gaskill, Greenville, Ohio.

OHIO INDEPENDENT TELEPHONE ASSOCIATION. Secretary, O. O. Welsheimer, Columbus, Ohio.

OHIO SOCIETY OF MECHANICAL, ELECTRICAL AND STEAM ENGINEERS. Secretary, F. W. Ballard, Cleveland, Ohio.

OHIO STREET RAILWAY ASSOCIATION. Secretary, Charles Currie, Akron, Ohio.

OKLAHOMA ELECTRIC LIGHT, RAILWAY AND GAS ASSOCIATION. Secretary, Galen Crow, Guthrie, Okla.

OLD TIME TELEGRAPHERS' AND HISTORICAL ASSOCIATION. Secretary, Frank J. Scherrer, New York, N. Y.

ORDER OF THE REJUVENATED SONS OF JOVE. Mercury, C. B. Roulet, Dallas, Tex.

PACIFIC COAST ELECTRIC TRANSMISSION ASSOCIATION. Secretary, Samuel G. Reed, Portland, Ore.

PENNSYLVANIA ELECTRIC ASSOCIATION. Secretary, E. S. Smith, Towanda, Pa.

PENNSYLVANIA STATE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, H. E. Bradley, 135 South Second Street, Philadelphia, Pa.

PENNSYLVANIA STATE STREET RAILWAY ASSOCIATION. Secretary, Charles H. Smith, Lebanon, Pa.

PIKE'S PEAK POLYTECHNIC SOCIETY. Secretary, E. A. Sawyer, Colorado Springs, Colo. Meetings, second Saturday of each month.

RAILWAY SIGNAL ASSOCIATION. Secretary, C. C. Rosenberg, Bethlehem, Pa. Next annual meeting, Louisville, Ky., October 12-14, 1909.

SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION. Secretary, Arthur L. Williston, Pratt Institute, Brooklyn, N. Y.

SOUTH DAKOTA INDEPENDENT TELEPHONE ASSOCIATION. Secretary-treasurer, E. R. Buck, Hudson, S. D.

SOUTHWESTERN ELECTRICAL AND GAS ASSOCIATION. Secretary, J. A. Myler, Jr., 608 Juanita Building, Dallas, Tex.

STREET RAILWAY ASSOCIATION OF THE STATE OF NEW YORK. Secretary, J. H. Pardee, J. G. White & Co., New York, N. Y.

TEXAS INDEPENDENT TELEPHONE ASSOCIATION. Secretary, Charles F. Speed, Texarkana, Ark.

UNDERWRITERS' NATIONAL ELECTRIC ASSOCIATION. Secretary Electrical Committee, G. M. Goddard, 55 Kilby Street, Boston, Mass.

VERMONT AND NEW HAMPSHIRE INDEPENDENT TELEPHONE ASSOCIATION. Secretary-treasurer, G. W. Buzzell, St. Johnsbury, Vt.

VERMONT ELECTRICAL ASSOCIATION. Secretary, C. C. Wells, Middlebury Electric Light Company, Middlebury, Vt.

VIRGINIA STATE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, B. L. Fisher, Rocky Mount, Va.

WESTERN ASSOCIATION OF ELECTRICAL INSPECTORS. Secretary, W. S. Boyd, 382 Ohio Street, Chicago, Ill.

WESTERN SOCIETY OF ENGINEERS (Electrical Section). Secretary, J. H. Warder, 1737 Monadnock Block, Chicago, Ill.

WISCONSIN ELECTRIC AND INTERURBAN RAILWAY ASSOCIATION. Secretary, Clement C. Smith, president Columbia Construction Company, Milwaukee, Wis.

WISCONSIN INDEPENDENT TELEPHONE ASSOCIATION. Secretary, J. C. Crowley, Jr., Superior, Wis.

ALABAMA LIGHTING AND TRACTION ASSOCIATION. Temporary secretary, F. K. Jackson, Mobile, Ala.

DATES AHEAD.

American Roentgen-Ray Society. Annual meeting, New York city, December 28-30.

Chicago Electrical Show. Coliseum, Chicago, Ill., January 16-30, 1909.

American Association for the Advancement of Science. Annual meeting, Baltimore, Md., January, 1909.

Northwestern Electrical Association. Annual meeting, Milwaukee, Wis., January, 1909.

RECORD OF ELECTRICAL PATENTS.

Issued (United States Patent Office) December 1, 1908.

905,130. MACHINE FOR CRIMPING ELECTRIC RESISTANCE-WIRES. James I. Ayer, Cambridge, Mass., assignor to Simplex Electric Heating Company, Boston, Mass. Filed December 6, 1906. Two loop forming devices are arranged to lay the loops alternately in opposite directions.

905,131. ELECTROMAGNETIC STOP MECHANISM FOR SHUTTLE-LOOMS. Daniel Bacon, New York, N. Y. Filed February 8, 1907. An electrically-operated clutch governs the movements of the driving shaft of the loom.

905,136. ALTERNATING-CURRENT MAGNET. Thomas E. Barnum, Milwaukee, Wis., assignor to Cutler-Hammer Manufacturing Company, Milwaukee, Wis. Filed April 15, 1905. There is an iron shroud surrounding the coil with an air-gap so proportioned that the self-induction of the coil will permit the passage of sufficient current to attract the armature, but when this is attracted only sufficient current can pass to maintain the armature in position.

905,141. INSULATOR. Lawrence L. Bogue, East Orwell, Ohio. Filed May 28, 1907. An elongated cylindrical body has continuous U-shaped grooves intersecting at its rounded ends.

905,159. ELECTRIC HEATER. Austin C. Dunham, Hartford, Conn. Filed April 16, 1907. An electric radiator comprises a corrugated receptacle with a central casing dividing it into communicating chambers with an electric-heating coil in the bottom portion.

905,176. DEVICE FOR SUSPENDING BATTERY-CRADLES. Emil Gruenfeldt, Cleveland, Ohio, assignor to The Baker Motor Vehicle Company, Cleveland, Ohio. Filed January 23, 1908. A series of independent hangers for suspending the storage battery in an electric vehicle.

905,229. ELECTRIC CALL-BELL. Christian Reinker and William Reinker, Lakewood, Ohio. Filed April 27, 1908. A separate magnetically-controlled device is adapted to limit the vibratory movement of the hammer to a buzzing sound.

905,230. ELECTRICAL CONDUCTOR FOR DYNAMOS. Walter J. Richards, Milwaukee, Wis., assignor to National Electric Company, Milwaukee, Wis. Filed August 15, 1904. A pigtail carbon brush.

905,266. SIGNAL APPARATUS. Leonidas G. Woolley, Lima, Ohio, assignor to John C. Riley, Lima, Ohio. Filed August 31, 1906. A magneto-electric signaling system includes a main-line testing mechanism having a magneto with an overbalancing weight.

905,308. AUTOMATIC RAILROAD SIGNAL. William H. Harris, Stark, Mont. Filed December 16, 1907. Electrically-operated block-signal system.

905,312. HEADLIGHT. Theron L. Hiles, Chicago, Ill. Filed July 23, 1908. An electric lamp is located in a parabolic reflector composed of glass silvered on its outer surface.

905,326. ELECTRICAL TEMPERATURE READER AND RECORDER. George E. Kirk, Toledo, Ohio, assignor to William A. Baker, Toledo, Ohio. Filed June 26, 1907. Contains an indicating instrument and a temperature-measuring instrument capable of producing variation in a resistance.

905,327. ELECTRIC SIGNALING SYSTEM. Edward E. Kleinschmidt, New York, N. Y. Filed August 7, 1907. An alternating-current system for a direct-current railway has a transformer in each block.

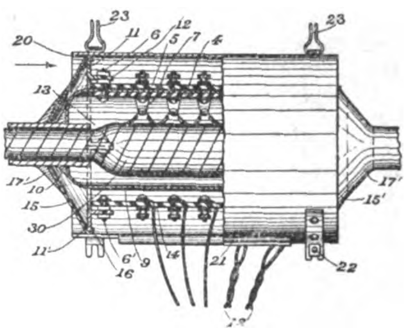
905,347. CABLE TERMINAL. James E. McMeen, Galesburg, Ill. Filed May 21, 1906. A sealed sleeve contains a set of insulated terminals; a second set of terminal posts is supported by the flanges of the sleeve, and a cover is clamped upon the flanges, forming a housing for both sets of terminals.

905,349. SEAL FOR ELECTRIC WIRES. Orrie W. Neal, Burton W. Shaw and Harry J. Howarth, Portland, Me. Filed August 15, 1908. A seal for the ends of insulated wires consists of a two-part casing adapted to inclose the bare ends.

905,351. TROLLEY RETRIEVER. Clarence Norland, Los Angeles, Cal. Filed March 7, 1907. A casing contains a reel and a slack-adjusting spring connected therewith.

905,361. METHOD OF PRODUCING AND UTILIZING OZONE. Henry N. Potter, New Rochelle, N. Y., assignor to Cooper-Hewitt Electric Company, New York, N. Y. Filed January 6, 1904. The method consists in passing current between the electrodes inside a container previous to ozonizing radiation.

905,364. FLOOR BOX AND RECEPTACLE. Nelson H. Raymond, Trumansburg, N. Y., assignor to Alice C. Patterson, New York, N. Y. Filed July 7, 1908. A socket is mounted on a saddle in the receptacle.



905,347.—CABLE TERMINAL.

905,370. DELIVERY APPARATUS FOR DELIVERING MAIL, PARCELS, OR THE LIKE. Shelton H. Roby, Dublin, Ga. Filed January 9, 1908. A suspended carrier system has means for energizing the track wires and connections for leading the current to and from the motor of the carrier.

905,378. FIRE AND TEMPERATURE ALARM OR INDICATOR. George L. Smith, Aberdeen, Scotland. Filed May 22, 1908. A pneumatically controlled electric fire and trouble alarm.

905,402. METHOD OF REMOVING CARBON FROM METALLIC FILAMENTS. Werner von Bolton, Charlottenburg, Germany, assignor to Siemens & Halske, A. G., Berlin, Germany. Filed June 2, 1908. The method consists in highly electrically heating the film containing the carbon in an atmosphere of acetic acid vapors.

905,414. METALLIC INSULATOR PIN. Charles G. Ette, St. Louis, Mo., assignor to Ette Investment Company, St. Louis, Mo. Filed December 24, 1907. Consists of two sections that are provided on their longitudinal edges with interlocking teeth.

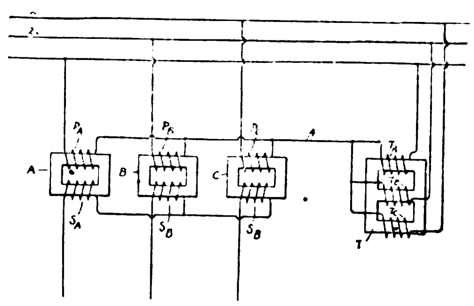
905,458. GLOBE CLEANER FOR ARC LAMPS. Robert H. Read, Schenectady, N. Y., assignor to General Electric Company. Filed October 25, 1906. In combination with the inner globe are electromagnetic means for rotating it and one or more stationary wipers inside the globe.

905,459. FLAT-IRON STOVE. Edwin W. Rice, Jr., Schenectady, N. Y., assignor to General Electric Company. Filed May 11, 1908. A flat-iron stand comprises an upwarding projecting support for an iron and contact terminals adjacent thereto.

905,468. ELECTRIC SIGN. John P. Shearer, Nyack, N. Y. Filed April 16, 1908. A casing has panels mounted in it and a bar carrying the lamp support.

905,478. INCANDESCENT LAMP. Alfred Swan, New York, N. Y., assignor to General Electric Company. Filed June 7, 1905. A portion of the leading-in wire is curled up in a cavity in the web.

905,483. ELECTRIC-LIGHT-BULB SHIELD. Benjamin R. Williams, English, Ark. Filed March 18, 1908. Each of a pair of shields adapted to enclose the bulb is provided with a neck fitting the neck of the socket, and a binding-band encircles the necks of the shields.



905,509.—THREE-PHASE DISTRIBUTION SYSTEM.

905,495. ELECTRORESPONSIVE DEVICE. Edward A. Buckman, Chicago, Ill., assignor of one-half to Harry L. Felio, Chicago, Ill. Filed July 1, 1907. An electromagnet comprises a spirally-advancing laminated core, laminated pole pieces and a coil wound on the core.

905,497. TELEGRAPH TYPEWRITER. George A. Cardwell, New York, N. Y., assignor to American Telegraph Typewriter Company, New York, N. Y. Filed March 18, 1907. Consists of a number of main and secondary circuits and selectable magnets responsive to a characteristic kind of impulse.

905,503. NON-EXPLOSIVE FUSE. Frank B. Cook, Chicago, Ill. Filed May 3, 1906. An enclosed fuse is filled and sealed so as to exclude all air therefrom.

905,508. CONTROL OF SEPARATELY EXCITED GENERATORS PROVIDED WITH AUXILIARY POLES. Lionel Fleischmann and Georg Stern, Berlin, Germany, assignors to General Electric Company. Filed March 11, 1908. The generator has an auxiliary series field and means for "killing" this when the main field circuit is broken.

905,509. SYSTEM OF DISTRIBUTION. Lionel Fleischmann, Berlin, Germany, assignor to General Electric Company. Filed April 10, 1908. A three-phase system has three single-phase transformers Y-connected and a three-phase Y-connected reactance, with its neutral point connected to the neutral point of the single-phase transformers.

905,512. DYNAMO-ELECTRIC MACHINE. Charles M. Green, Lynn, Mass., assignor to General Electric Company. Filed August 12, 1903. The armature has a shield formed of a strip of woven fabric cut on the bias and means for gathering the edges of the strip to cause it to closely embrace the armature.

905,513. SIGNAL SYSTEM. John L. Hall, Schenectady, N. Y., assignor to General Electric Company. Filed January 30, 1908. A number of receiving devices are provided with magnet windings.

905,514 and 905,515. ARC LAMP. Cromwell A. B. Halvorson, Jr., Lynn, Mass., assignor to General Electric Company. Filed October 31, 1906, and April 6, 1907. There are means for operating the negative electrode to cause it to strike the positive one. The second patent describes the clutch mechanism.

905,520. FEED MECHANISM. Bengt M. W. Hanson and Frederick W. Post, Hartford, Conn., assignors to Pratt & Whitney Company, Hartford. Conn. Filed April 12, 1907. An electric circuit has a member provided with means for limiting the action of the feed mechanism.

905,537. RECEIVER ARRANGEMENT FOR WIRELESS TELEGRAPHY. Gerhard Jahr, Berlin, Germany. Filed June 12, 1907. Comprises a coil, a receiver, adjustable terminals therefor, a lever connected with one of the terminals and adapted to contact the other terminal under the action of electric waves.

905,554. INSULATED CONDUCTOR. Joseph I. Mitchell, Schenectady, N. Y., assignor to General Electric Company. Filed September 14, 1903. The conductor for use in making edgewise-wound coils consists of a flat strip and a flat strip of insulating material adjacent to one side.

905,557. ARC-LIGHT ELECTRODE. Berthold Monasch, Berlin, Germany, assignor to General Electric Company. Filed May 16, 1906. Composed of one or more metallic compounds mixed with several per cent of silicon carbide.

905,572. METHOD OF STRIKING VOLTAIC ARCS. Albert J. Petersson, Alby, Sweden. Filed November 3, 1905. The method consists in leading gases through a furnace chamber, striking arcs between the electrodes and moving the arcs by means of magnetic action to electrodes of other circuits of higher intensity.

905,588. ELECTRIC CONTROLLER. Ralph R. Root, Cleveland, Ohio. Filed February 8, 1906. A resistance controller there are provided a pair of carbon pencils and solenoids for moving one pencil so as to increase the distance between them and thereby produce resistance.

905,589. SYSTEM FOR CONTROLLING MOTORS. David E. Ross, Brookston, Ind. Filed May 18, 1907. A pneumatically-operated controller for traction motors.

905,594. DEVICE FOR LOCATING A MOLTEN DISTRIBUTING FUSE. Ferdinand Schultz, Münster, Germany. Filed February 15, 1907. The fuse on melting opens an electric connection between the feeder and pilot wires, and indicates its location by a voltmeter at the central station.

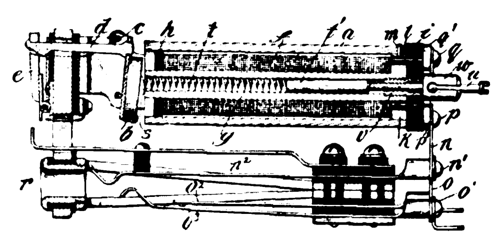
905,597. ELECTRIC FLUID HEATER. James S. Smyser, Harwich, Mass., assignor to General Electric Company. Filed April 4, 1908. Comprises a fluid receptacle and a pair of electrodes therein, each composed of parallel-spaced plates connected at one end.

905,599. NEGATIVE-POLE ACCUMULATOR ELECTRODE. Edward Sokal, Chicago, Ill. Filed August 22, 1907. Consists of a perforated envelope completely filled with active material containing a small percentage of lead dust.

905,619. TELEPHONE-EXCHANGE APPARATUS. Ernest E. Yaxley, Chicago, Ill., assignor to Monarch Telephone Manufacturing Company, Chicago, Ill. Filed September 26, 1905. A combined magneto drop and spring jack.

905,621. ALTERNATING-CURRENT HIGH-FREQUENCY GENERATOR. Ernest F. W. Alexanderson, Schenectady, N. Y., assignor to General Electric Company. Filed February 6, 1905. An inductor-type alternator has two rotating discs tapering toward their center and carrying projections on the inner sides of the peripheries.

905,625. EXPLOSION ENGINE. Elmer Apperson, Kokomo, Ind. Filed July 3, 1906. A pair of spark plugs extends into the cylinder, one being connected to a magneto and the other to a battery.



905,619.—TELEPHONE DROP AND JACK.

905,628. TELEGRAPHIC REPEATING APPARATUS. William E. Athearn, New York, N. Y., assignor to American Telephone and Telegraph Company. Filed April 29, 1908. The circuit has at each of two stations a current-reversing transmitter and a polarized relay.

905,666. ELECTRODE. Albert G. Davis, Schenectady, N. Y., assignor to General Electric Company. Filed July 29, 1904. In an apparatus for electrical treatment of gases there are electrodes containing magnetite and means for establishing an arc between them.

905,675. BRUSH HOLDER. Hermann F. T. Erben, Schenectady, N. Y., assignor to General Electric Company. Filed October 17, 1903. A pivoted frame to which the brush is rigidly secured is provided with a spring having an adjustable spiral portion and reversely curved portion.

905,697. MOTOR-CONTROL SYSTEM FOR ELECTRIC VEHICLES. Max R. Hanna, Schenectady, N. Y., assignor to General Electric Company. Filed March 16, 1908. There are a number of electrically-controlled switches for connecting and regulating two pairs of motors and a master controller governing the controlling switches.

905,703. INCANDESCENT ELECTRIC LAMP. Herman J. Jaeger, New York, N. Y. Filed November 4, 1907. Construction of a multiple metallic-filament lamp is described.

905,713. SELF-REGULATING ELECTRICALLY-PROPELLED VEHICLE WITH LIMITED VARIATIONS IN INTENSITY. Louis Krieger, Paris, France. Filed January 10, 1906. A generator arranged to deliver constant watts has an exciter.

905,734. AUTOMATIC SELF-STARTER. Charles H. Miller, Milwaukee, Wis., assignor to the Cutler-Hammer Manufacturing Company, Milwaukee, Wis. Filed April 10, 1905. An electromagnetically operated starter for electric motors.

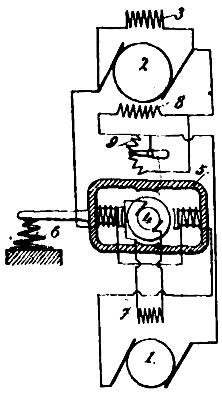
905,746. OPERATING DIRECT-CURRENT GENERATORS IN MULTIPLE. Frank W. Peek, Jr., Schenectady, N. Y., assignor to General Electric Company. Filed April 8, 1908. There is a voltage regulator for each generator containing a main-control magnet having a differential winding.

905,752. POWER-GENERATING SYSTEM. Edmond Rosenberg and Edgar W. Mix, Paris, France, assignors to General Electric Company. Filed April 23, 1907. There are in combination an electric generator, a turbine driving the same, a flywheel located in a chamber and a condenser which creates a vacuum in the chamber to decrease rotation losses of the flywheel.

905,761. SEALING-CAP FOR ELECTRICAL APPARATUS. Joseph G. Swallow, Brooklyn, N. Y., assignor of one-half to Frank W. Smith, New York, N. Y. Filed March 6, 1908. A reversible perforated cap is provided with an opening for the appliance.

905,773. GROUNDING CLAMP FOR ELECTRIC WIRES. Wheeler H. Vibber, New London, Conn., assignor of one-half to the Gillette-Vibber Company, New London, Conn. Filed April 11, 1908. A wrought-metal strap is bent to a circular form and has two projections which are perforated for the reception of the binding-screw.

905,781. TELEPHONE RECEIVER. Nathaniel Baldwin, Heber, Utah, assignor of one-half to William Witt, Heber, Utah. Filed January 29, 1908. A magneto telephone has a permanent magnet, an armature and means for causing both poles of the magnet to act on each side of the armature.



905,713.—SELF-REGULATING GENERATOR.

905,782. ELECTROMAGNETIC SWITCH. Thomas E. Barnum, Milwaukee, Wis., assignor to Cutler-Hammer Manufacturing Company, Milwaukee, Wis. Original application filed April 15, 1905. Divided and this application filed July 5, 1906. This is a modification of No. 905,136.

905,784. MOUNTING FOR TROLLEY HEADS. Joseph J. Bennett, Pittsfield, Mass., assignor of one-half to Loando B. Estes, North Adams, Mass. Filed August 6, 1906. There is an arm integral with the base piece and adapted to be mounted in the upper end of the trolley pole.

905,785. ELECTROLYTIC SOLUTION FOR ZINC PLATING. Celestino Bianco, New York, N. Y. Filed July 16, 1907. Contains sulphates of zinc and iron and acetate of sodium.

905,790. MOTOR CONTROLLER. Albert H. Buckelew, Newark, N. J. Filed February 21, 1905. The pilot motor actuates the controller step by step and a pair of directional switches controls the pilot motor without stopping the main motor in going from one position to another.

905,792. SNAP SWITCH. Frank S. Capello, Schenectady, N. Y., assignor to General Electric Company. Filed October 8, 1907. In combination with the spindle are catch-plates having a slot and an actuator engaging the slot and adapted to slide transversely of the spindle.

905,797. ALTERNATING-CURRENT CLUTCH. Albert G. Davis, Schenectady, N. Y., assignor to General Electric Company. Filed March 27, 1908. A magnetic clutch has two movable members, one with a laminated core and a winding thereon and the other with a short-circuited conductor in inductive relation to the winding.

905,800. ARC LAMP. John T. H. Dempster, Schenectady, N. Y., assignor to General Electric Company. Filed February 29, 1904. Renewed April 7, 1906. Comprises a non-consuming electrode, a consuming electrode co-operating therewith and means for heating the former to thereby heat the latter electrode.

905,805. DYNAMO-ELECTRIC MACHINE. Samuel S. Forster, Schenectady, N. Y., assignor to General Electric Company. Filed July 20, 1905. The teeth of a laminated armature core are provided with U-shaped stiffening members.

905,812. ELECTRICAL CONNECTOR. Preston E. Gilling, Camden, N. J., assignor to Novelty Electric Company, Philadelphia, Pa. Filed March 20, 1906. Comprises a piece of tubing with a section flattened and bent into a loop to form a clamp having a terminal with a socket.

905,814. DYNAMO-ELECTRIC MACHINE. Charles M. Green, Lynn, Mass., assignor to General Electric Company. Original application filed August 12, 1903. Divided and this application filed November 8, 1904. The pole shoe is formed of iron laminated perpendicularly to the plane of revolution of the armature.

905,815. APPARATUS FOR THE MAGNETIC SEPARATION OF ORE. Gustaf Gröndal, Djursholm, Sweden. Filed June 25, 1907. A set of magnets is arranged above the overflow between the vessels.

905,816. CLOCK. Augustus L. Hahl, Chicago, Ill., assignor to Hahl Automatic Clock Company, Chicago, Ill. Filed September 26, 1903. An electromagnet is energized at predetermined intervals thereby actuating the rack bar and winding the spring.

905,817. DYNAMO-ELECTRIC MACHINE. Fred B. Howell, Schenectady, N. Y., assignor to General Electric Company. Filed April 17, 1908. A pole piece comprises laminations and fastening bolts therefor extending all the way through the pole piece.

905,819. AUTOMATIC CARRIER SYSTEM. Carl W. Larson, Schenectady, N. Y., assignor to General Electric Company. Filed January 2, 1906. An automatically-controlled and electrically-driven cable moves the car.

905,824. ELECTRIC EXHIBITOR. Bert H. Winters, Annapolis, Md. Filed December 17, 1907. A casing with a sight opening contains a drum revolved by an electromagnet and an electric-lighting arrangement.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired December 8, 1908:

464,490. ELECTRIC RAILWAY SIGNAL. C. E. Buzzell, Leaf River, Ill.

464,505. CONDUIT CONDUCTOR FOR ELECTRIC RAILWAYS. W. H. Knight, New York, N. Y.

464,510. AUTOMATIC FIRE-ALARM TELEGRAPH. M. Martin, Malden, Mass.

464,513. ELECTRIC FARE-RECORDING SYSTEM. B. S. Molyneaux, Minneapolis, Minn.

464,540. TIME-REGISTERING DEVICE FOR ELECTRICAL CURRENTS. W. D. Wilder and W. Cobb, Jr., Brockton, Mass.

464,547. ARMATURE WINDING FOR DYNAMO-ELECTRIC MACHINES. C. R. Arnold, Philadelphia, Pa.

464,557. ELECTRIC RAILWAY SYSTEM. L. O. Dion, Natick, Mass.

464,643. PROTECTOR FOR TELEPHONES. J. L. W. Zietlow, Aberdeen, S. D.

464,665. SECONDARY BATTERY. I. L. Roberts, Brooklyn, N. Y.

464,666. ELECTROMAGNETIC MOTOR. N. Tesla, New York, N. Y.

464,667. ELECTRICAL CONDENSER. N. Tesla, New York, N. Y.

464,676. ELECTRODE FOR SECONDARY BATTERIES. W. Morrison, Des Moines, Iowa.

464,677. ELECTRICAL TRANSFORMER. A. Poleschko, St. Petersburg, Russia.

464,682. ELECTRIC ARC LAMP. A. G. Waterhouse, Hartford, Conn.

464,683. ELECTRIC METER. A. G. Waterhouse, Hartford, Conn.

464,780. TROLLEY FOR ELECTRIC RAILWAYS. J. W. Schlosser, Washington, D. C.

464,822. SYSTEM OF DISTRIBUTING ELECTRICITY. T. A. Edison, Menlo Park, N. J.

464,897. TELEGRAPH KEY. L. F. Robare, Au Sable Forks, N. Y.

ELECTRICAL REVIEW
AND
WESTERN ELECTRICIAN

VOL. LIII, No. 25. CHICAGO, SATURDAY, DECEMBER 19, 1908. ISSUED WEEKLY

BY THE
ELECTRICAL REVIEW PUBLISHING COMPANY.
CHARLES W. PRICE, President.
STEPHEN H. GODDARD, Vice-President. H. S. TUTHILL, Secretary.
PHILIP S. DODD, Manager. C. W. FORBRICH, Assistant Treasurer.

PUBLICATION OFFICE: 204 DEARBORN STREET, CHICAGO.

The present publication comprises: ELECTRICAL REVIEW, VOL. LIII, No. 25; WESTERN ELECTRICIAN, VOL. XLIII, No. 25.

EASTERN DEPARTMENT . . . . 13 Park Row, New York.
E. E. Wood.

CONTENTS.

UNREASONABLE FRANCHISE EXACTIONS.

Very often the city fathers, in drawing up an ordinance for the regulation of the relations of the municipality and a corporation exercising a quasi-public function, are eager to impose exactions which will make it imperative for the company desiring a franchise to treat all people applying for service exactly alike. This has led to considerable loss on the part of the telephone companies, and the reason for it is not hard to see if any close analysis is made of the possibility of irresponsible persons demanding and securing service for which they are unable to pay.

The electric-lighting company usually brings its feeders to a point either outside or just inside of a residence or factory building, and the gas company is responsible only so far as its street mains and house connections are concerned. The telephone company, on the other hand, takes care of its own street distribution and carries its wiring scheme through the building to its own instrument, which it leaves ready for service upon the premises of the subscriber.

In discussing the subject of credit co-operation among manufacturers, and the necessity for a close analysis of the credit of those asking for service from a quasi-public corporation, a prominent telephone man, speaking before an electrical gathering recently, stated that under its ordinance, his company was expected to give service to everybody who demanded it. At one time during the present year there were something like 3,800 requests for nickel-telephone service. A credit department was established, and these 3,800 requests were dumped into this department, and in a short time 2,500 of them were returned as being unable to pass muster for apparent ability to pay their bills. The installation of wiring and the telephone instrument for these subscribers would have occasioned a very great investment upon the part of the telephone company, so it was decided to address a brief letter to these apparently irresponsible ones, with the request that they post a deposit of $9 with the telephone company as a guarantee of good faith, with the understanding that if the bills were properly met for a period of one year, they would have returned to them the sum of $10, which would, of course, include their original payment and interest thereupon. Out of 2,500 possible subscribers thus addressed only 400 either put up the deposit of $9 or secured a guarantee from parties such as the telephone company could deem reliable. As a further indication of the irresponsibility of large numbers of people who will exact a service, even though unable to pay for it, out of another 2,500 subscribers who actually did receive service, 300 fell down the first month, 400 the second month and something like 600 the third month.

CENTRAL-STATION LOCATION OUTSIDE CITIES.

Within the past two or three years the location of central stations outside the immediate centres of distribution which they serve has become sufficiently frequent to justify comment. While local conditions are obviously responsible for this departure from former practice in cases that have been given thorough engineering study, the tendency is none the less marked. Usually the problem has been solved in connection with the re-location of a plant at a time when the growth of the old station demands a large addition in capacity, with provision for a number of years' expansion. The progress lately made in the field of high-voltage transmission justifies taking a wider view of the power supply question for any given community than was possible in the old days when the ideal of the plant designer was to locate his machinery as close to the centre of distribution as real estate restrictions and water supply would permit.

There are more advantages in locating a plant at some distance from an urban centre than are always appreciated, in view of the general tendency of central stations in the majority of communities to adopt 2,300 volts as the standard of service. The increasing cost of real estate, the rapid growth of the power business and the expansion of lighting loads, the tendency of city taxation to mount upward, the development of adjacent territory and property, the difficulty and great cost of purchasing land for extension, smoke restrictions, crusades against noise, restrictions against coaling at the most convenient hours, and the pressure of commerce against the station walls, all point the way toward a location of the plant ultimately on a site less cramped, following the course of many industrial establishments in their re-location in the suburban sections of large municipalities, with new equipment and better opportunities for development along the best lines.

The location of a station on a piece of land in a small town adjacent to the city mainly supplied enables the company to design the plant according to its own ideas, without interference from over-zealous municipal regulations. At moderate cost, usually, sufficient land can be obtained to provide for many years' growth along whatever lines engineering development dictates, and the operation of the new station can be vastly facilitated by the low cost of space on the new property. It is a great mistake for a company building a new station on a suburban or rural site, to crowd the apparatus as though operation were to be carried on in a congested city district, and yet one of the latest examples of a transplanted station illustrates a case of this kind. In the instance in mind, the old steam plant in the centre of the city became inadequate in both capacity and economy of power production, and a new station with the latest turbine equipment was built by the company in an adjoining town, to supply all power through the original plant location as a distributing substation. Unfortunately the new station is so crowded that passage through the building is devious and difficult, the handling of machinery parts is less flexible than is desirable, and the operation of the station is clearly hindered by the cramping of equipment. The location of the plant on land so cheap that the expansion of the next twenty-five years, if not of the next half-century, is provided for by the area purchased, ought to have predicated a station of ample design, even at some relatively small increase in first cost of building, piping and wiring runs.

The more remote site similarly affords larger and less costly coal-storage facilities. If the plant is located beside a railroad track or on a navigable stream, the cost of coal per ton may be considerably reduced through lessened expense in handling, avoidance of teaming, ease of installing telpher systems or electric traveling grab-bucket equipments of moderate cost which might be precluded entirely in the more constricted site of the old station. The cost of water for boiler feed may be considerably reduced also, by a location outside the city. In not a few cases the housing of the station employees may be solved in a much better way than is possible in the city proper, although the provision of hours of labor that will allow a certain amount of relaxation is a very important factor in retaining the services of desirable men when a plant is moved to some out-of-the-way suburban point.

The only objection of serious character against these locations of the newer central stations is the question of service reliability and cost of transmission. The integrity of the transmission to the substations or distributing centres must be absolutely established. At the moderate voltages usually required in these central-station services, with distances rarely exceeding a dozen miles or so, there is little excuse for the failure to maintain continuous service. A 13,200-volt transmission offers no difficulty to an experienced engineer in these days, and where 2,300 or 6,600 volts are adequate, interruptions should be few and far between. When the service of a good-sized city depends upon a plant located outside the centre of population, it may pay to install at least two lines in the interest of service continuity. The cost of transmission, including fixed charges, needs to be carefully figured in planning the location of a station in a suburban territory, together with the probable development of loads in the vicinity of the plant. Where the cost of power production is high at the old plant on account of obsolete or depreciated equipment, unfavorable operating conditions, or excessive taxes, a line of moderate length is not likely to interpose a transmission cost unfavorable to the location of the new plant outside. An important point to make certain of before beginning construction is the rate of taxation or possible exemptions to be secured the company through its location in a given suburb. The small town can afford to make it an object to the lighting company to locate in it, generally speaking, for even a moderate rate of taxation on a plant of, say, 5,000 kilowatt rating, means a revenue of large proportions from the point of view of town administration. If concessions of this kind can be secured, the lighting company will generally be able to repay them by bringing increased business of various kinds to the town, giving it new life industrially through cheap power, increasing in and out freight and express business, helping the postal receipts and bringing business to certain retail merchants through the visits of officials to the community in connection with the plant affairs, and by improving the standards of street illumination.

THE GAS APPLIANCE EXPOSITION.

One of the recent events of considerable interest to manufacturers of electrical appliances and to central-station men was the Gas Appliance Exposition, held under the auspices of the National Commercial Gas Association, and the American Gas Institute, in Chicago. The exhibit was remarkably complete, and attracted a great deal of attention. The gas men received and deserved a considerable meed of praise for the extent to which this industrial indication of the magnitude of the gas industry was handled, and, as one of the prominent gas men put it: "The gas men are wondering why they didn't do this thing long ago, now that they have found out that they really could do it."

One thing was noticeable, and this must bring a good deal of satisfaction to the designer of electrical fixtures and the central-station man: The chandeliers which attracted the greatest amount of attention, and which, per se, were most usable and likable, both from an æsthetic and utilitarian standpoint, were fashioned absolutely in imitation of electric fixtures and appliances. One fixture, however, an excuse for the design of which it is hard to find, was a gas arc using inverted gas mantles and an alabaster round globe; in carrying out the imitation of the arc lamp even the casing which the manufacturers of electric arcs must use in order to protect and conceal the works of the lamp has been conscientiously copied.

Electrical ignition systems seem not to be very popular, for not one was noticed at this very extensive exposition of gas appliances. Pilot-lighting systems operated by compressed air and by electromagnetic control, and also pyro-electric spontaneous igniters, were in evidence. At the present time a combination pneumatic-pilot-lighting system appears to be the most dependable, as was pointed out in one of the papers dealing with the improvements in gas-ignition devices read at the recent convention of the Illuminating Engineering Society.

Another feature which attracted much notice from the electrical men in attendance at the exposition was the fact that in almost every case where motive power was required, small electric motors were used, where it would appear there was an excellent chance for the exploitation of small gas engines, if any were available.

THE ELECTRICAL INDUSTRY IN GREAT BRITAIN.

Some five years ago a council of ponderous intellects passed a resolution declaring, in so many words, that although the engineers of Great Britain had contributed largely to the wealth and standing of the nation and the world, technical education and recognition of technical worth appeared to be backward. This was all occasioned through the passage by the British Parliamentary committees of certain stultifying restrictions and regulations which, it was feared, would make impossible the development of new inventions and their application to electrical undertakings in Great Britain.

Certainly, the unwise, though well-meant, restrictions imposed by governmental policy in Great Britain would appear to retard many applications; as, witness the borrowed developments which have recently been applied to the solution of both lighting and traction problems.

Mr. W. M. Mordey, in his presidential address before the Institution of Electrical Engineers, of Great Britain, quite recently, took this topic as the subject for some characteristic remarks. After careful compilation and considerable research, based upon the assumption that the value of any utility should be measured by the amount by which each unit of the population is served by such utility, Mr. Mordey finds that in no direction is the electrical engineering profession backward in England; in fact, it is ahead, and well ahead. He does not wish it to appear, however, that there are not restrictions and hindrances to the British engineer employing many valuable inventions which should reasonably and logically be developed in Great Britain. But the fact remains, says this doughty champion, that the aspersions which have been cast upon British engineering progress, and which have originated, unfortunately, in England itself, have no real foundation.

WATER RESOURCES INVESTIGATION.

The annual report of the director of the United States Geological Survey emphasizes the wisdom of determining the extent and character of the water resources of the country. Prominent engineers have long advocated the extension of government investigations of water resources, and it is a well-known fact that the work in the United States is not commensurate with that done in many European countries. If the United States were to provide for the prosecution of water resources investigations on a scale of thoroughness equal to that of Switzerland, for example, it would appropriate $11,000,000 annually, a sum 110 times greater than the present annual appropriation for similar work in this country.

Aside from the development of power, which would be a contemporary advantage, together with irrigation, increased facility for inland-waterway navigation, and the canalization of streams not now available for water transportation, the saving of waste caused by floods would be considerable. It is estimated that the annual damage caused by floods in the United States must be at least $100,000,000, and it is stated that in many parts of the country the proper expenditure of an amount equal to one year's flood loss would prevent further floods. In other parts of the country the cost would probably equal the losses of two or more years, but in every locality prevention could be accomplished by an expenditure equivalent to the losses from the floods of a few years.

Whatever means may be finally adopted to prevent the devastation by floods and to conserve the power resources and the possibilities of waterway transportation, the data must be gathered largely by government surveyors. It is quite necessary, then, that the Geological Survey, or whatever department of the Government may undertake this work, be aided by such appropriations as will enable the speedy and thorough compilation of the data now so ardently desired by constructing and contracting engineers.

The Mexican Light and Power Company.

A controversy has arisen over the Mexican Light and Power Company, certain directors of the Bank of Montreal being arrayed on one side, and Dr. F. S. Pearson, of New York, with certain Montreal and London associates, on the other.

The company was formed under the corporation laws of the Dominion of Canada, in 1902, by Dr. Pearson, to develop waterpowers on the Necaxa River, ninety miles from the city of Mexico. The bonds outstanding amount to $12,000,000, and there is $13,000,000 stock. A very successful power demand has been built up, and current has been satisfactorily transmitted to a number of mining camps and to the City of Mexico, where the company controls the electric-lighting facilities.

Some time ago Dr. Pearson succeeded in securing control of the Mexican Tramways Company, and later sought to arrive at equitable terms for the acquisition by the tramways company of the Mexican Light and Power Company. Some of the directors of the company, headed by President E. S. Clousten, managing director of the Bank of Montreal, opposed Dr. Pearson's proposals.

A special meeting will be held in Montreal on December 30 to consider a lease of the Mexican Light and Power Company to the Mexican Tramways Company, Dr. Pearson and his associates representing more than the twenty-five per cent of the stock which is necessary to issue a call for a special meeting.

The tramway company seeks a lease of the Mexican Light and Power Company on the basis of the payment of fixed charges, seven per cent on the preferred stock, and four per cent on the common stock. The directors of the light and power company say that the earnings of that company are now at the rate of seven per cent on the common stock, and that the earnings of the tramways company are at the rate of less than two-and-one-half per cent on that company's $6,000,000 of stock.

Formal Opening of Patapsco River Plant

On November 28 the Patapsco River plant of the Patapsco Electric and Manufacturing Company, Baltimore, Md., was opened with formal ceremonies. The Patapsco River plant, it will be recalled, was constructed about a year ago, and in the technical journals at that time was given particular attention, as the development is unique in combining in one structure both power house and dam, the turbo-generators being located within the concrete abutment.

The plant has now been running for some time, but owing to numerous changes which were found necessary, especially the rebuilding of the power tunnel to make it air and water tight against floods, continuous operation did not begin until three months ago. The formal public opening was held after all was assured to be in complete working order. Five hundred visitors were present November 28 upon the invitation of the power company and witnessed the starting up of the plant by the young daughter of Victor G. Bloede, president of the company. Following the ceremonies, a luncheon, cooked by electricity derived from the waterpower, was served to the guests.

The completed plant cost $175,000. The dam and power house creates a head of twenty-six feet, and contains two 300-kilowatt alternators, generating at the transmission potential of 11,000 volts for distribution to Ilchester, Ellicott City, Catonsville and Southwest Baltimore.

Electrical Engineers Entertained by the National Commercial Gas Association.

In connection with the Gas Appliance Exposition, which was conducted, under the auspices of the National Commercial Gas Association and the American Gas Institute, from December 7 to December 12, at the First Regiment Armory, Chicago, Ill., a spirit of the greatest cordiality was effected by reason of the co-operation of the Chicago Section of the Illuminating Engineering Society and the officers and members of the National Commercial Gas Association.

On the evening of Thursday, December 10, the Chicago Section of the Illuminating Engineering Society was entertained at a banquet at the Auditorium Hotel, tendered by the National association, and later in the evening the Section was the guest of the Gas Appliance Exposition, being welcomed by A. Cressy Morrison, who made a brief address commendatory of the activity of electrical engineers in bringing to the fore the advantages of better illumination.

Mr. Morrison brought to the attention of the illuminating engineers some interesting figures concerning the extent of the gas industry. The investment in the United States today amounts to $1,600,000,000. Gas is supplied to 38,500,000 consumers, and of this number there is one gas meter to every seven people. The output for the year at the present time is about 200,000,000,000 cubic feet.

Indiana Public Utilities Bill.

At the second annual convention of the Indiana Manufacturers' and Shippers' Association, held at Indianapolis, Ind., on December 10 and 11, the principal business was the consideration of a public utilities bill to be introduced in the next session of the Legislature. A number of public-utilities men were present.

The bill advocated by the association is sweeping in its provisions, and seeks to include waterworks, telephone and telegraph, electric light and power, and transportation companies of every description, and is patterned largely after the Wisconsin law. Exception was taken to the advisability of framing such a bill for Indiana, and it was contended that transportation utilities have already been brought well under state control. A legislative committee was appointed to prepare a bill providing for a public-utilities commission, and present it to the Legislature for passage. The following men were chosen: C. C. Perry, Indianapolis Light and Heat Company; L. C. Boyd, Indianapolis Water Company; C. H. Graf, Indianapolis Gas Company; T. P. Sylvan, Central Union Telephone Company; Charles H. Norton, Indianapolis Telephone Company; J. R. Zartman, secretary of the Indiana Manufacturers' and Shippers' Association; C. M. Kimbrough, Muncie, a bridge manufacturer; M. D. Wilson, Madison, cotton-mill owner; and C. C. Foster, lumber dealer. S. S.

Wireless Conference Bill in the French Chamber.

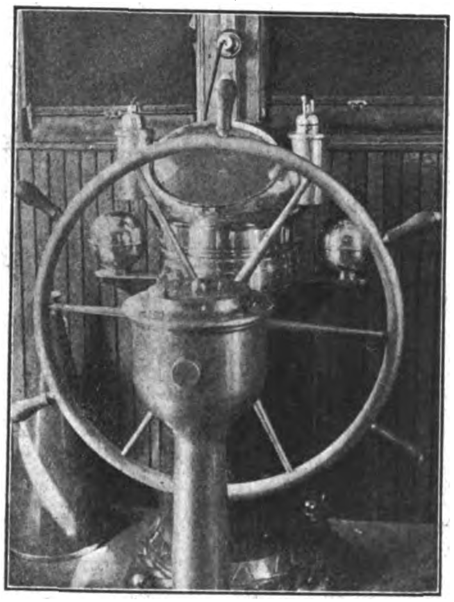
A bill for putting in force the decisions of the Berlin Wireless Telegraphy Conference of November, 1906, as embodied in an international convention, has been laid before the French Chamber. The conference has fixed wave-lengths, one of 300 metres, the other of 600 metres, for the transmission of public messages by the wireless current. All stations must be able to produce and to receive one, at all events, of these two wave-lengths. All public correspondence must be restricted to one of these wave-lengths. A coast station, however, can use other wave-lengths for long-distance communications, or for messages other than those transmitted by the public, provided that these wave-lengths are not under 600 metres and are not more than 1,600 metres. Stations on board ship must use the 300-metre wave-length. They are permitted, however, to use other wave-lengths as well, provided that these are under 600 metres. —*Nature (London), December 4.*

The Lighting and Power Arrangements and Other Uses of Electricity in a Modern Steamship.

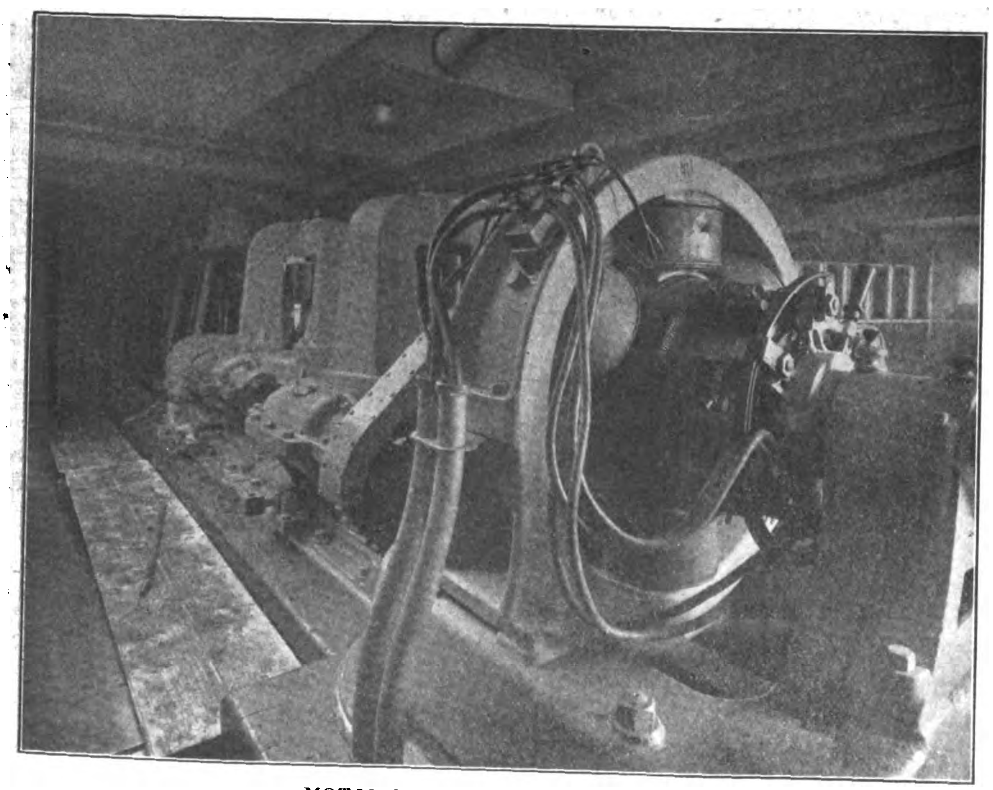
By Louis P. Zimmerman.

About the illumination, the lighting system and the size of the electrical equipment of a modern steamship, the average engineer knows very little. The giant steamship Minnesota which has been operated for some years between Seattle, Wash., and Oriental ports by the Great Northern Steamship Company, presents a very interesting problem in interior lighting adapted to the peculiar and special needs of a steamship. On shipboard every part of the equipment, particularly the generating units and the switchboards, is crowded into as small a space as possible, and at times this space is totally inadequate for the proper handling of the apparatus. This crowding is necessary, for a ship is a compact unit and every inch of space counts; hence the engineer is not allowed spacious quarters for the machines which form the electrical system.

The Minnesota is a combined passenger and freight-carrying vessel, 630 feet in length, 73.6 feet in beam and fifty-six feet deep from the keel to the saloon deck amidships. There are five complete decks in the ship proper and three more in the ship house, giving a total depth of eighty-eight feet from the upper navigating bridge to the keel. These decks are named from the bottom up: orlop, lower, 'tween, main and upper which is the weather deck. In the ship house are the promenade, bridge and boat decks with the navigating bridge above all. There are accommodations for 318 cabin passengers, 1,500 troop or steerage passengers and a crew of 230 men.



STEERING WHEEL, PILOT HOUSE.



MOTOR-DRIVEN STEERING GEAR.

The total deadweight capacity is 23,000 tons of 2,240 pounds in addition to the weight of the stores and supplies, while a cubical capacity of 28,000 tons of forty cubic feet each is available for the storage of light cargo. The ship has complete double bottoms, each capable of floating the ship in event of damage and between which sufficient water ballast can be carried to obtain the desired stability in case of light loading. A longitudinal steel bulkhead extends the entire length from keel to main deck dividing the ship into two separate water-tight sections, and twelve transverse thwartship bulkheads give twenty-six water-tight compartments.

The 15,000-horsepower power plant driving the two twenty-foot twin screws and the 450-kilowatt lighting plant on board, would require a good-sized building and foundations of great depth and solidity on land, but here they are crowded together in the lower part of the hull supported on beams and almost regarded as a necessary incumbrance.

The boilers, sixteen in number, are of the Niclausse water-tube type, with a total heating surface of 39,264 square feet. The furnaces are coal-burning and have a storage bunker capacity of 4,000 tons with a reserve of 2,000 additional tons. The engines are in two complete units on the two sides of the vertical bulkhead. Each unit consists of three vertical, inverted, direct-connected, triple-expansion, Midvale Steel Company's marine engines with cylinder diameters of twenty-nine, fifty-one and eighty-nine inches and a common stroke of fifty-seven inches, designed to develop 4,800 horsepower per cylinder, running at seventy-eight revolutions per minute, with a steam pressure of 230 pounds. All the cylinders are jacketed with steel galvanized lagging and provided with a continuous circulation of live steam.

Two three-blade, true screw propellers with a pitch of twenty-two feet nine inches are driven separately through two shafts each 232 feet long. This immense power of the engines and propeller is transmitted to the frame of the ship through a cast-iron thrust shaft and bearing, eighteen-and-one-eighth inches in diameter and fourteen-feet-four-inches long, with nine collars two-and-one-half inches wide and twenty-seven-and-five-eighths inches in diametei, running in an oil bath.

Next is the electrical plant and its many applications on board ship. Something over 450 kilowatts are developed for light and power in the little plant located in the forward part of the engine room on a platform at the level of the orlop deck extending across the width of the ship, three units being on each side of the bulkhead. Six single-acting, inverted, vertical, compound automatic Westinghouse engines direct-connected to six six-pole, direct-current, 110-volt generators, running at 300 revolutions per minute, generate the electricity needed. Each unit is closely surrounded by a protective iron railing and all connections are carefully insulated to avoid possible contact. The floor around the pedestals of the machines is of gridiron grates and steam pipes pass around and over the units leaving barely room for a man to pass through. Two switchboards, one for each set of three units, are located on the two sides of the dividing bulkhead and are provided with the necessary instruments, simply and compactly arranged. Power is distributed from these main boards on eleven lighting and seven power circuits to various smaller boards in other parts of the ship. The three-wire system is used throughout for power and light. The total installed motor capacity is 1,566 horsepower.

A brief mention of the various uses of power in the ship is almost necessary to get an idea of the extent of its use.

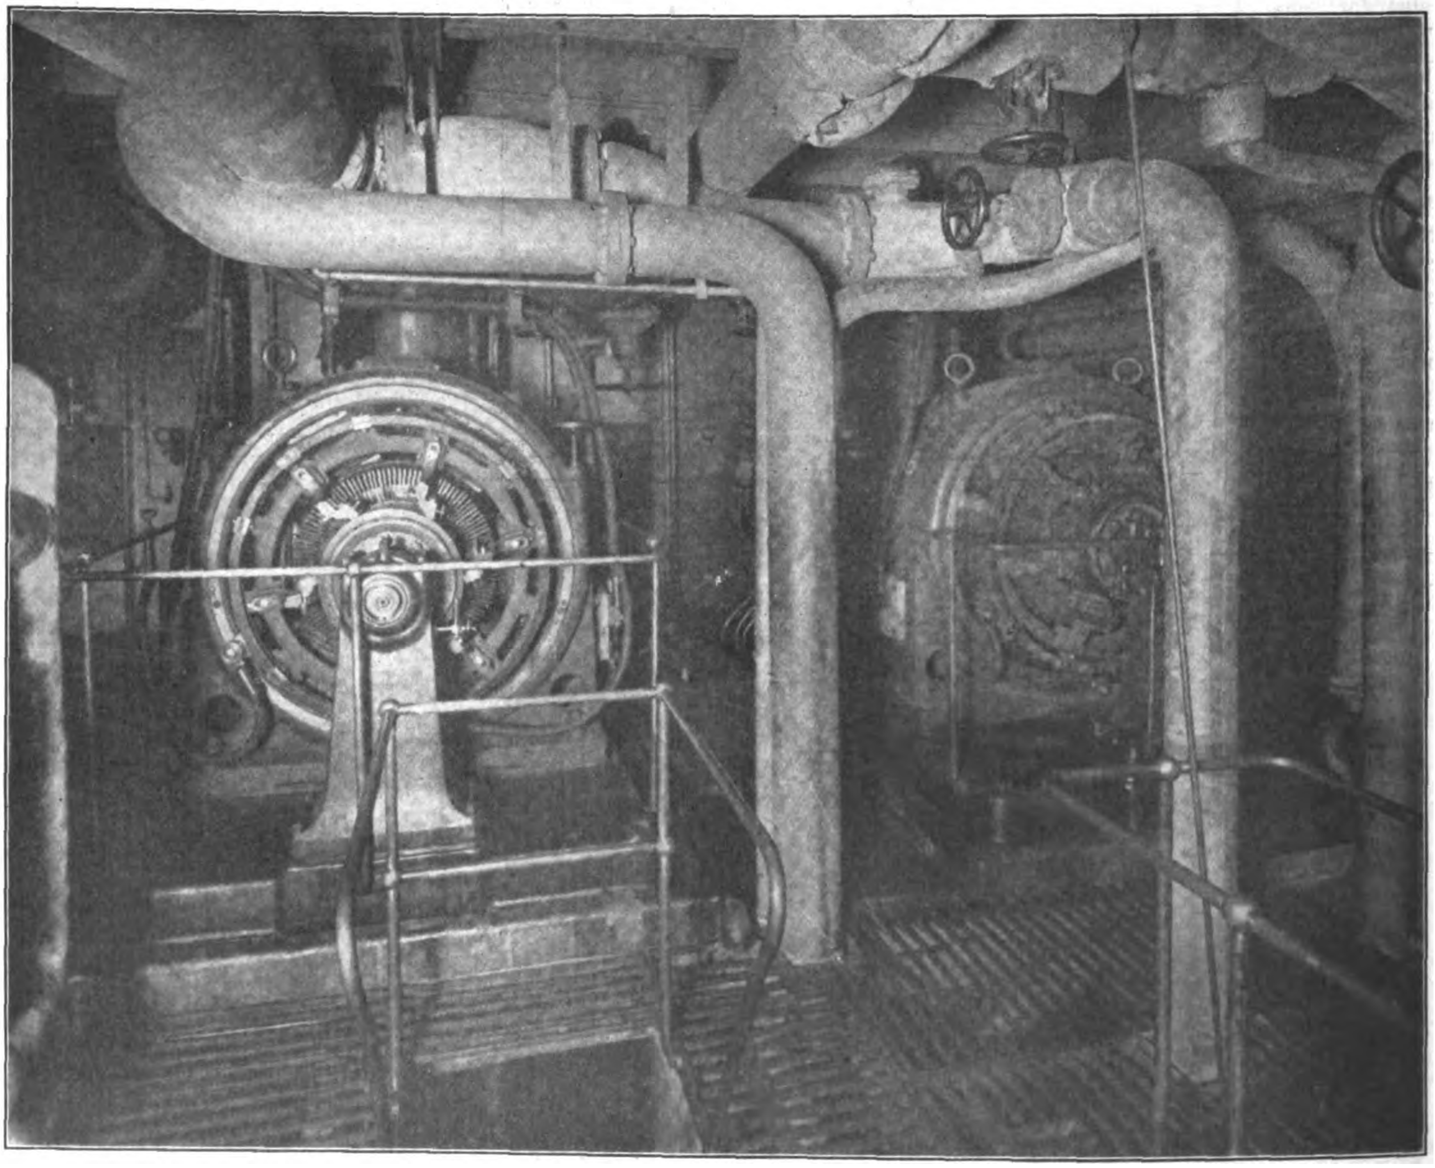
The ventilation consists of a fresh-air supply and exhaust system. Fresh air taken in over the heating coils is delivered to the staterooms and saloons, seventy-two Westinghouse motor-driven exhaust fans being used in the entire ventilating system.

The steering gear is in duplicate, steam and electrically driven; the electrically-driven being used for landings and emergencies and the steam for regular work, both sources of power being directly connected to the steering quadrant.

The refrigerating plant consists of two brine refrigerating machines, two air coolers, an ice-making machine, and water cooler for filtering drinking water. Two seventy-five-horsepower motors are direct-connected to the two thirty-ton marine ammonia compressors.

Electrically-operated winches are installed throughout. There are in all thirty-eight cargo winches geared directly to General Electric series-wound, armored motors fitted with railway-type controllers, as follows: Twenty-six twenty-five-horsepower, capacity of 3,000 pounds; eight 40-horsepower of 5,000 pounds; one 7,000 pounds; two 10,000 pounds and one 14,000 pounds.

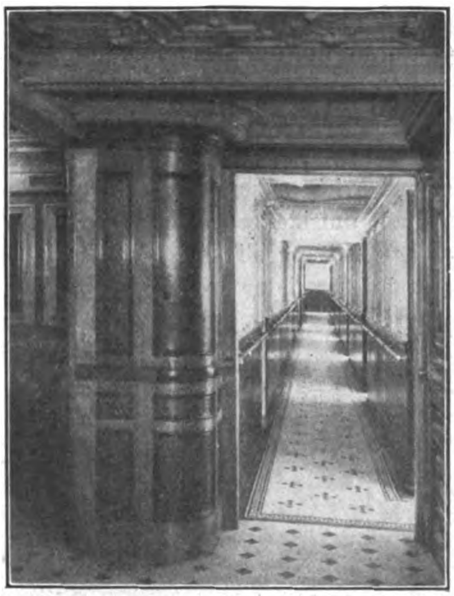
Interior communication in the Minnesota is the same as in a first-class hotel, being complete with telephone system, call-bells, fire-alarms, electric whistle con-



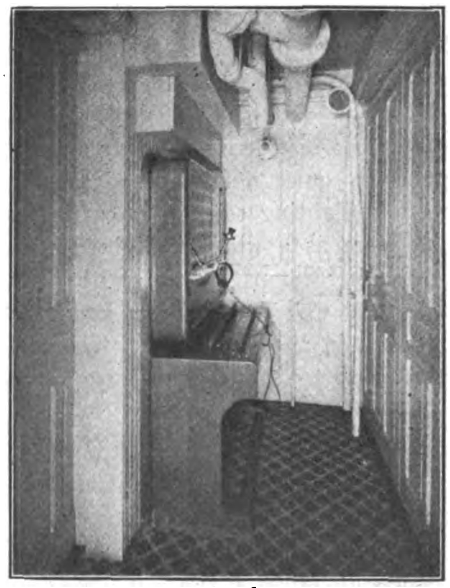
WESTINGHOUSE GENERATOR, FOR POWER AND LIGHTING SERVICE.

trol, electric cooking and electrically operated dumb waiters.

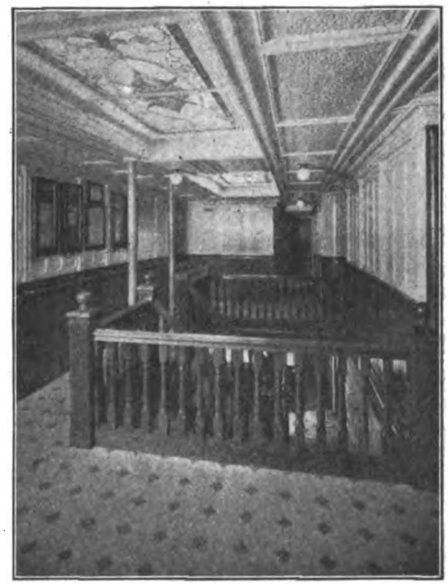
Passenger accommodations on board are entirely dependent for heating on electric heaters, there being apparently nothing else to satisfactorily take their place.



CABIN HALLWAY, PROMENADE DECK.



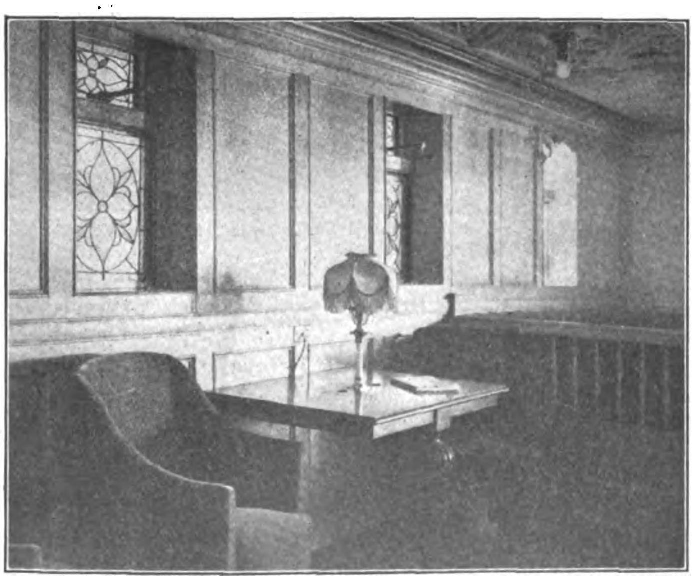
CENTRAL TELEPHONE STATION.



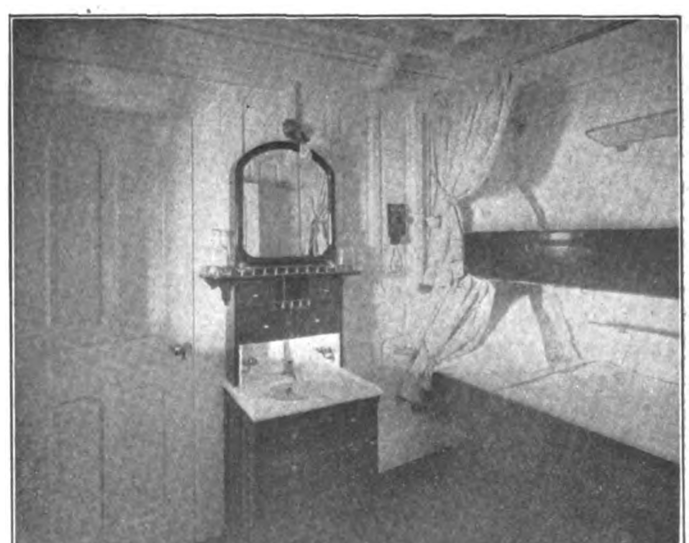
MAIN STAIRCASE, BRIDGE DECK.

Electric heaters are an unprecedented departure from ordinary heating practice, but are superior on shipboard to steam radiators because they occupy less room, are more easily regulated and not liable to tip over. One electric heater is found in each stateroom.

Modern vessels demand the use of electricity for lighting. The incandescent



DESK IN LADIES' MUSIC ROOM—PORTABLE LAMP AND PENDENT INCANDESCENTS.



STATEROOM, PROMENADE DECK—NOTE TELEPHONE, MIRROR AND BERTH LIGHTS.

lamp is no small factor in bringing out the harmonious effects of the interior furnishing of the Minnesota. Luxurious finishings and superb furnishings would appear like dismal caverns were it not for the art of the electrical engineer in illuminating and beautifying the interior. In the staterooms, saloons, library, smoking room and passenger quarters, special ornamental fixtures are installed, and the design and finish of these fixtures harmonize with the interior furnishings.

In the steerage, engine rooms, firerooms, cargo holds, on the decks and all other places where there is any moisture or exposure to weather, fixtures with a steam tight globe and heavy protection guard are installed.

The Minnesota is equipped with a twenty-four-inch General Electric searchlight on the pilot house which projects a beam of light of sufficient density to render plainly visible on a dark, clear night a light-colored object ten feet by twenty feet at a distance of about 5,000 yards. A searchlight is a necessity on board ship, and its importance and usefulness are demonstrated in picking up buoys in channels, signaling between ships at sea and in making landings in the dark.

All parts of the Minnesota are open to the public and the quarters occupied by the officers are luxuriantly finished. The pilot house is finished in wainscoting of dark stained cherry with an upper paneling of quartered oak. The chart room and captain's sitting room are done in cherry and oak with dark upholstery.

The public are interested mainly in the passenger accommodations, and these will now be described in detail. The main dining saloon in the forward end of the mainhouse on the upper deck extends the full width of the house. The walls are finished in dark, rich mahogany side paneling with rectangular windows in the front and side of the saloon, fitted with mahogany sliding shutters and stained glass panes topped with Adams-Westlake ventilators. The ceiling design is stucco work of cream and gold; the ceiling and beam cappings are staff paneling; the electric fixtures and exhaust vents are in alternate panels. The furniture is all mahogany, finished in old gold and draperies. There is a seating capacity for 190. The whole scheme of lighting the dining saloon is to give it a rich, pleasant appearance to set off the white dishes and tables, the silverware and the various viands. This plan is followed out in the dark, rich mahogany background and furniture, and the dark carpet on the floor. The tables are illuminated by lamps covered with frosted globes which give a diffused light on the tables, the ceiling and the faces of the diners, producing an abundance of light, but entirely eliminating any glare or direct exposure to bare lamps. The forty lamps in the ceiling arranged in alternate rows, give a rich, full coloring to the entire room.

From the saloon a grand double staircase of mahogany with a curved baluster leads to the social hall and the staterooms on the promenade deck. This hall is built around the double staircase leading to the dining saloon and up to the upper deck. Special twisted posts and a pleasing curve make the banister fit in well with the symmetry of the room. Directly above the staircase is a stained-glass skylight surrounded by white scroll work and rectangular capped beams between which are six ceiling lamps covered with large frosted globes set deep into an ornamental rosette, illuminating the hall evenly and satisfactorily, but not nearly as intensely as the dining saloon.

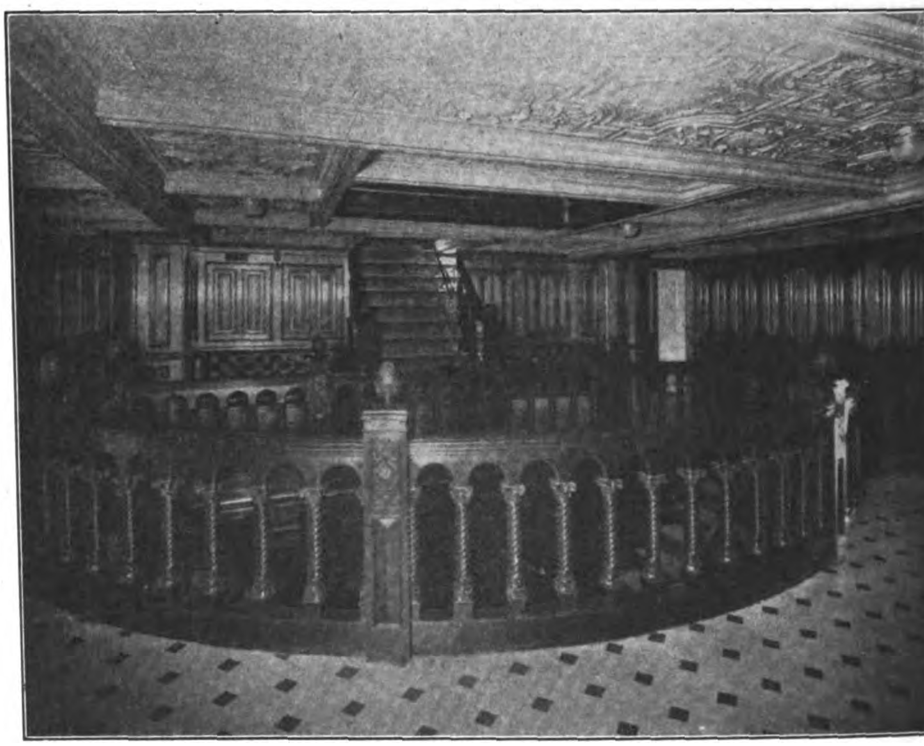
Above the saloon and off from this hall on the starboard side of the promenade deck, is the ladies' parlor and music room, which is the most comfortable and inviting part of the whole ship. The furniture, the writing tables and the grand piano give the room a desirable homelike appearance. The color scheme is sky-blue and silver, the walls are paneled with bird's-eye maple and the ceiling is of tinted staff finished throughout in light gold furnishings. A light olive-green upholstery, light draperies and stained-glass windows all suggest cheer and comfort. All tables have drop lamps with heavy ornamental shades throwing the light directly on the table for reading or writing. In the ceiling some eight-candlepower bare lamps, set in long slender rosettes, give a gentle white light to the room as a whole, but are not sufficient in number or power to cause annoyance or distress to the eyes. There are no pronounced shades or colors, all being a uniform, cozy, harmonious silver and white.

In the adjoining library is an entirely different style, all the paneling being of dark oak, and all the tables and furniture of dark upholstered leather. The color scheme is buff and gold artistically worked out in stucco conveying a sense of grandeur, quiet and impressiveness. A two-fold lighting scheme is carried out. The room as a whole is lighted with a few ceiling lamps covered with frosted globes, set well down with a long rosette arranged in the centers of octagonal designs between the transverse ceiling beams. Bare lamps, set two and two, on either side of the central columns, just above the tables, provide light for reading. While sufficient, the illumination is hardly the best for a library, being too high and too much diffused.

The smoking room, on the after-end of the bridge deck, has panelings of Flemish oak, natural finish, and rosewood wainscoting, harmonizing with the rosewood furniture, upholstered in red leather. In the center of the ceiling, which is worked out in stucco and light oak, paneled and capped, is a large raised skylight of colored glass. Directly above the glass is a fan to draw off the smoke. All the lamps are bare, placed in the ceiling, and of sufficient number to well light the interior, which reflects on the reddish colored furniture, and gives that brilliant, festive effect common to smoking apartments.

The long halls leading through the ship are fairly well and sufficiently lighted with lamps enclosed in frosted-glass globes set in the ceilings, spaced about twenty-five feet apart. The lower halls are uniformly dark, the upper part white, and all are provided with a convenient handrail.

The staterooms are finished in white enamel, with mahogany and oak fittings. All are outside rooms, provided with a window, sliding blinds, stained glass and a hinged ventilator open at the top. Each room is electrically lighted with two bare lamps. Electric reading lamps, placed above each berth, under the control of the occupant, are so arranged that it will not disturb the other berth. All the second and third class rooms are well lighted by artificial light, but some, of course, are inside rooms, and daylight is impossible to get.



SOCIAL HALL AND MAIN STAIRCASE—PROMENADE DECK—HEMISPHERES AND INCANDESCENT LAMPS.

On deck, and below in the engine rooms, the boiler rooms and the holds, bare incandescents are arranged for special work wherever needed.

As a whole, the lighting is better planned and carried out with more care than in a majority of offices and residences. The 1,300 lamps distributed over eight decks of the immense ship give, roughly, one lamp per 150 square feet, and sufficient and satisfactory illumination in all parts.

NEW YORK SECTION, ILLUMINATING ENGINEERING SOCIETY.

DR. STEINMETZ ON "LIGHT AND ILLUMINATION."

The meeting of the New York Section of the Illuminating Engineering Society, held in the Engineering Societies Building on December 11, was very well attended, as might have been expected, owing to the fact that the speaker of the evening was Dr. C. P. Steinmetz.

When the section chairman, W. W. Freeman, called the meeting to order some seventy-five members were present and, from the attention given the speaker, it may be said that they not only enjoyed, but also profited by the lecture. Dr. Steinmetz selected a very broad topic, "Illumination and Illuminating Engineering," and treated it in like manner. He stated that the physiological aspects of the subject were much more important than the physical ones, owing principally to the effect upon the eye of both direct and reflected light and the lack of it in many ways.

Calculations.—As far as calculations were concerned, the importance of using the lumen as the unit of efficiency, as well as flux, was brought out, as, owing to the varying characteristics of our sources and also because the tube lamps, such as the Moore and Cooper Hewitt, have no candlepower values which are of any importance. Besides, the lumen has a definite relation to the intensity on the illuminated plane, or, in other words, the flux density.

Although we may determine accurately, by means of illuminometers, the intensity in foot-candles or flux density, this physical quantity will not be of great value unless we have fulfilled the physiological requirements.

That there are many factors in illumination problems which bear directly upon the use of our eyes, was very forcibly presented by the speaker. For instance, high intrinsic brilliancy will lower the visual sensibility, even though the lamps are not directly in the field of vision; either too high or too low flux density causes considerable strain. Complete uniformity is also undesirable, as the eye will have no opportunity to rest. On the other hand, the change from high to low intensity must be within comparatively small limits, for although the eye can withstand great changes in this respect, they must not be rapid ones. We can see fairly well at night under a full moon, when the flux density will be but a fraction of one foot-candle, and also under full sunlight at noon, when the flux density will be several thousand times that amount, but we cannot go from a dim room into clear sunlight without decided eye strains.

Color.—As far as color was concerned, Dr. Steinmetz did not refer to the effect of ultra-violet rays, but it is obvious that this troublesome feature will be eliminated when we use shades which cut down the intrinsic brilliancy.

When light sources of various colors are desired, this can be accomplished by means of colored shades, and in this connection he called attention to the fact that color differences vary rapidly under various intensities.

Shadows.—Probably the most interesting feature of the lecture was the importance, clearly shown, of the use of shadows, and it would seem as if the crux of the matter was in the success with which this feature was carried out. In very few cases no shadows are desirable, a drafting board being one of them; but in the majority of cases we need shadows without sharp edges, and this can be accomplished by means of a combination of diffused and direct lighting.

In domestic lighting, the diffusion can usually be obtained by means of reflection from walls and ceilings. The fact that we require at least some of the light within the line of vision, can be readily demonstrated by a visit to an auditorium where only indirect lighting is employed. Dr. Steinmetz summarized the defects in our present systems as follows:

1. Improper combinations of high and low flux density.
2. Sources of high intrinsic brilliancy in the field of vision.
3. Improper combinations of direct and indirect lighting.
4. Not enough shadows.
5. Shadows with very sharp edges.

He seemed to think that many of the difficulties could be overcome if we studied the effects of daylight in the various rooms of a house.

Street Lighting.—Dr. Steinmetz stated that uniform intensity was the chief desideratum, but on account of economy it would necessarily have to be of low intensity. In order to obtain these results the light source, if placed within twenty feet of the ground, should give its maximum intensity about ten degrees below the horizontal and to be as near white as possible in color, owing to the poor refraction from roads and buildings. The objection to this method was that shadows from an object are very long and therefore objectionable, as the appearance of the object is distorted. Another objection is that a source such as he described would be of too high intrinsic brilliancy, and if diffusing globes were used the light near the horizontal would be considerably reduced. Therefore the solution of the matter was to place the lamps forty or fifty feet high and use enough of them to obtain uniform illumination.

In answer to a question he stated that the system in Detroit had not been successful, as it was altogether too pretentious and not enough lamps had been used.

In answer to the many criticisms which have been made of the lighting in this country as compared with Europe, he stated that the conditions here are entirely different, and cited as an example the fact that the city of Schenectady with only 70,000 population covers the same area as the city in Germany where he was born, which has a population of 450,000.

Dr. Steinmetz called attention to the fact that, although we could not afford to light our streets by placing the units very high as suggested, we could afford to do it in exposition work, and he hoped that general illumination would be provided in this manner at one of the expositions to be held in the future.

At the January meeting two papers on street lighting will be presented, one by W. C. Allen, electrical engineer for the District of Columbia, and one by S. S. Rhodes, of the New York Edison Company.

Enlarged Power for Interstate Commerce Commission.

An entering wedge to enlarging the jurisdiction of the Interstate Commerce Commission is contained in a bill introduced in the Senate by Senator Burkett of Nebraska. It places the telephone companies, electric-light companies, and the gas companies in the District of Columbia under control of the Commission.

As telephone companies do an interstate business, should the bill become law, such telephone companies may also be placed under jurisdiction of the Commission.

Rome has appropriated about $4,000,000 for an electric plant, the generating apparatus for which will be placed twenty-two-and-one-half miles distant.

The New York, New Haven & Hartford Railroad Electrification.

Two-Hundred-and-Thirty-second Meeting of the American Institute of Electrical Engineers, New York, December 11.

The two - hundred - and - thirty-second meeting of the American Institute of Electrical Engineers was held in the Engineering Societies Building, New York city, on Friday evening, December 11. Secretary Ralph W. Pope announced that eighty-eight associates had been elected to membership and that John Knowlton Robinson, of New York and South America, had been transferred to full membership.

President Louis A. Ferguson called the meeting to order and introduced W. S. Murray, electrical engineer of the New York, New Haven & Hartford Railroad, who presented the paper of the evening, an abstract of which follows:

THE LOG OF THE NEW HAVEN ELECTRIFICATION.

BY W. S. MURRAY.

Unlike steam traction, where the number of links in the delay chain is but one, electric traction has its delay chain composed of three links; namely, the power house, line, and locomotive. A failure in any one of these links may produce train delay or delays.

In the conception of the form of power house, line, and locomotive to be used in the New Haven system, ignorance and lack of experience led those pertinently interested in its success to believe that while the chain of power generation, and its transmission and utilization for traction, was of a new character, that its links, however, were made up of principles long recognized and reliable. They were right in this conclusion, except that it did not include certain phenomena which could not have been anticipated, due to the combination of these old principles in the form of this new chain.

THE SERIOUS FAULTS.

Power House.—The electric power supply for the New Haven road is derived from four 11,000-volt steam turbine generators, three of which have an electric capacity of 3,750 kilovolt-amperes single-phase; the fourth unit consisting of a 6,000 kilovolt-ampere, three-phase generator, which can also supply single-phase current to the system.

Although the generators as originally designed were made exceptionally strong, and particular attention paid to their insulation, due to the necessity of grounding one phase, it was found that the utilization of so much single-phase current from a three-phase star-wound generator produced a stray magnetic field completely out of the path of normal lamination. As a result it was impossible to develop for continued operation more than sixty-six per cent of the normal rating of the generators. Overloads of any character produced abnormally rapid heating, making such operation dangerous, although the generators were guaranteed to carry 50 per cent overload for two hours, and 100 per cent overload for two minutes in order to meet the sudden drafts of currents required for a schedule such as exists on the New Haven road. The generators are today operating in the power house, fulfilling the guarantees mentioned previously.

Line Insulation.—Of the effect of steam locomotive discharges upon insulators, there was no initiative by which to be guided, and it became necessary to decide upon the factors of insulation that would be required. It was quickly noted that the greatest number of insulator failures occurred wherever the insulation was subject to the direct blast of the steam locomotive. To correct the difficulty, therefore, it was found necessary to double up on anchor insulators. The intermediate messenger insulators proved adequate and it was not found necessary to increase the impregnated stick insulation between trolley wires at curves, but wood stick insulators had to be added in series with the molded material insulator between the pull-off wire and pull-off post. The original insulators on the anchor-bridge switches were made of molded material and for them was substituted porcelain. It was not necessary to change the feeder insulators on the catenary bridge struts. While very little trouble has been experienced with the form of insulation used for supporting the feeders under highway bridges, it is anticipated that trouble will follow if this is not changed. The present form consists of the corrugated spool-type insulator, for which there will be substituted a regular porcelain double-petticoat insulator.

Today, instead of line failures being the rule, they have become the exception.

Circuit-breakers.—The momentary energy involved in a short-circuit produced upon a line fed by high power, high-speed turbines is very great. Under the sub-title "Power House" it was stated that the generators were operating under their guaranteed capacities. Internal heating, due to stray magnetic field, was the cause of the generators failing to meet their designed capacity. This heating was completely cured by the simple addition of a short-circuited winding surrounding the rotating member of the generator, similar to that used in the well-known squirrel-cage type of induction-motor rotors. It is interesting to note here, however, that while the heating is entirely eliminated by this short-circuited winding, its effect on the occasion of a short-circuit is to allow more current to flow.

The failure of circuit-breakers, either in the power house or on the line, naturally produced train delays of large or small magnitude. It was difficult to believe that these large circuit-breakers were incapable of taking care of the short-circuits, and some time was wasted in thinking this way. Therefore, we reluctantly but surely arrived at the conclusion that the conditions would have to be changed.

The remedy was simple. Instead of feeding the main line with a direct transmission straight from the power house bus-bars to the trolleys directly opposite the power house, the current was fed into the line over feeders connected to it at Port Chester and Stamford. For the feeder resistance, above described, there has since been substituted impedance coils installed in the leads of the generators.

Trolley Wire.—An examination of the hard-drawn copper trolley wire throughout its length proved that even after only a few months' operation upon it, its cross-section had been so materially reduced as to point to its short life with a continuance of operation upon it. Especially was this true in the vicinity of the many low highway bridges where the trolley wire approaches the bridge on a two per cent gradient. This fault and dilemma were indeed serious. The cause of the difficulty was perfectly apparent; namely, the hard spots in the line which existed at the hanger points.

Many suggestions were offered. None of them, however, offered the speedy installation that was paramount. Mr. McHenry, vice-president of the New York, New Haven & Hartford Railroad Company, made the suggestion that an auxiliary wire be suspended from the present copper wire by clips at its midpoint between the hangers, and followed up the suggestion that this auxiliary wire be made of steel, of the same cross-section as the 0000 grooved hard-drawn copper above it. It took two weeks for the manufacturer to draw two miles of this wire. It was installed immediately upon its receipt on the main line between Port Chester and Harrison. On the night of its completed erection a special seven-car train with two locomotives was operated upon it for several hours. Previously to the installation of the steel wire there had been installed a section of hard alloyed wire suspended in a manner similar to that of the steel. It is undeniably true that hard alloyed wire would, from a purely operative point of view, be the better of the two, and yet the commercial aspect, which would naturally include its cost, had to be considered, particularly in reference to so large an immediate order as one involving 100 miles of single-phase electric trackage. Again it is important to note that the steel, besides having the advantage of being a cheaper, harder, and stiffer wire, also possesses a lower coefficient of expansion and higher elastic limit, especially valuable characteristics for the service desired. The auxiliary wire construction on the main line, as described, prevails throughout the whole system, except at the approaches of and under a few very low highway bridges, where the contact system consists of two wires strung in the same horizontal plane.

The New Haven trains have been operating now on the auxiliary wire for several months, and absolutely no kinking has been noted at the hanger points, with the attendant result of a smooth and almost sparkless overhead contact.

Locomotives.—There were originally purchased thirty-five locomotives, which was considered an adequate number to take care of the New Haven passenger service. These locomotives, considered *per se,* were rated on a half-unit basis. That is to say, the half unit was designed to handle about seventy-five per cent of our trains, the remaining twenty-five per cent to be handled by two units. Only a short experience in commerical operation revealed two important facts. The first one of a very encouraging nature, the second, decidedly otherwise. The first was the proof that the two main parts of the locomotive, namely, the transformer and motors, had sufficient capacity to more than handle the manufacturer's guarantees. The second was the discovery that many of the auxiliary electrical and mechanical parts of the locomotive equipment were not of equivalent capacity. It was simultaneously apparent that more locomotives would be required to provide for an increase of train service and the reduction of time schedule, and an order was promptly placed for six additional ones; before accepting their design, however, a careful survey was made of all the component parts of the locomotives at hand, in order to determine the changes necessary to be incorporated in the six new engines. To accomplish this it was found necessary to make a number of electrical and mechanical changes.

The most important electrical changes made were in the switch-groups and brush-holders of the motors. The former lacked carrying capacity and the latter sufficient insulation. To these shortcomings were due the greatest number of our first train delays. The most important mechanical changes necessary were the reinforcement of the truck bolsters and installation of pony wheels, respectively, for locomotive with and without pony wheels.

With the exception of the installation of pony trucks, the six new electric locomotives arrived within five months of the date of their order. To be noted here is the marked value of the spring type of armature and field suspension begun with the New Haven locomotive motors, thus making flexible the entire motor suspension.

It seems to be the time and place, here, to draw attention to a point in design concerning the New Haven locomotives that has been so persistently misrepresented by those who seem to have been ignorant of the facts. The specifications upon which the locomotive units were purchased, as stated hereafter, were that each unit would handle a normal trailing load of 200 tons. The writer, by careful measurement of the weights of all the trains (trailing loads) in the New Haven service, found that they averaged 212 tons. It seemed good engineering that if seventy-five per cent of the service could be handled by locomotives rated upon a basis of 200 tons trailing load, that that would be the correct locomotive unit size; using two units for the remaining twenty-five per cent of the trains. Today, three years after this decision, we find that seventy-three per cent of our trains can be handled with single units, twenty-seven per cent requiring two units. The percentage is slightly different from the original, as the service is slightly heavier.

THE MINOR FAULTS.

Generator Burn-outs.—Previously to the rearrangement of the feeders or the installation of the choke-coils in the power station, the short-circuits that were experienced on the line naturally had a deleterious effect on the generators. The prodigious rush of current naturally produced severe strains in the armature windings, strains whose mechanical intensity was made manifest by the movements of the coils. Therefore, during this period of violent short-circuits, frequently the generator coils were grounded and burned out. Since the rearrangement of feeders or the installation of choke-coils, the violent short-circuits have disappeared and with them the damaging effects on the generators.

Hard Spots in Line.—The original main-line section-break consisted of a rectangular impregnated wood frame suspended under the anchor bridges. The trolley wires were carried on opposite sides of this rectangle lapping, of course, a sufficient distance in the center so as to permit a short period of simultaneous contact of the shoe with both trolleys, thus preserving continuity of current to the locomotive in passing from one section to another. It was found that these rectangular section breaks were prone to get out of shape, introducing a very rough spot in the line, its effect being, on the passage of the shoe, to draw long arcs which frequently extended themselves to ground. Our new section break, containing all the flexibility obtained by the auxiliary wire, has been constructed by simply staggering the messenger insulators of each trolley sixteen inches, thus permitting the anchor-bridge trolley wires of the same track to pass at this distance. Each trolley wire is dead-ended to a wood impregnated stick insulator, supported by the messenger of its opposite section. By this arrangement practically all inertia is taken out of the section break and a sparkless passage between sections is obtained.

Signal Wires.—The catenary bridge struts carrying the cross-arms for the by-pass or feeder wires, likewise carry the cross-arms upon which are installed the signal wires. The voltage placed on these signal wires is entirely distinct from the propulsion voltage, it being 2,200 volts and sixty cycles. The proximity of the wires of these two systems has been the cause of short-circuits between them, resulting in double failures. It would seem that as the signal system should be so completely separated from the propulsion system, it should be installed on an entirely separate pole line. If, however, right-of-way conditions make it absolutely necessary that the supporting structures of the catenary system should support also the signal wires, then the two circuits should be made as distinctive as possible, the propulsion system having its wires on the cross-arms on the railroad side of the struts, the signal wires being installed on the opposite.

Locomotive Current Collectors.—An efficient pantagraph shoe has proved itself a very difficult problem. The present cost is about 0.06 of a cent a locomotive-mile. We have made various experiments with aluminum, phono, copper, and steel rigid and spring-supported pantagraph shoes. While this feature does not present a serious aspect, it is none the less a most interesting study. Shoe life is also seriously affected by the amount of soot deposited by the locomotives upon the overhead wire. While we have obtained mileages varying between 600 and 1,500 miles per shoe with various types used, other roads of lesser speed and not subject to the effect of locomotive stack discharges, have obtained as high as 25,000 shoe-miles.

THE LOG OF OPERATION.

Electric Passenger Service.—So great was the demand for electric service that in July, 1907, long before we were ready, as the records of our operation have proved, the first commercial service was begun between New Rochelle and the Grand Central Station. With all speed possible the electrification was pushed eastward and local service was established from Port Chester in August, 1907. Local service from Stamford followed in October, and finally, on July 1, 1908, all through and local passenger trains were under electric schedule between Stamford and the Grand Central Station.

Individual and Collective Train-minute Delays in Electric Zone, Due to Failures in Power House, Line, and Locomotive.—The segregation of these failures based upon train-minute delays offers a quick and interesting comparison. It is to be noted that the last two months indicate a great improvement over the two preceding ones. From the chart have been taken the train-minute delays that have amounted to over 300 minutes per diem, which are treated separately in the following paragraph. It is interesting in reviewing the "cause of delay" to note that ninety per cent of the causes are of an inconsequent nature, and might be reasonably expected when considered in the light of an initiative service.

Serious Failures in System Causing Over 300-minute Delays.—A description of the cause of one applies to all of them, except those of July 16 and October 19. In every instance, excepting the two dates mentioned, the tie-up was due to simultaneous failure of several circuit-breakers, due to a short-circuit, thus temporarily disorganizing the distributing system, preventing the electrification of trolley wires.

On July 16, the White Mountain Express left the rails just east of Greenwich station, tying up both east-bound tracks, and causing excessive train-minute delays. Except for the electric rail bonds which suffered destruction, no other electrical apparatus was disturbed. One of the electric locomotives attached to this train was immediately returned to service, the other following it the next day after light repairs were made to its pilot and third-rail shoe mechanism.

On October 19, although the impedance coils in the generator station were in action, a ground occurring on the bus-bars of the anchor bridge directly outside of the power station, in combination with a defective circuit-breaker, produced a short-circuit which destroyed the operating mechanism of the breaker in question. This unfortunately occurred at a time when temporary connections had been made between the power house and line; on this account a serious delay was experienced in restoring the voltage to the line.

It is interesting to note that since the complete inauguration of electric service, the serious failures in the system have been reduced from five to one.

The Capacity of the Electric Locomotive.—The capacity of the electric locomotives was based upon their ability to handle a trailing load of 200 tons in local service with stops averaging those that exist between stations between New York and New Haven. As a matter of fact, the station stops between Stamford and New York average very much greater than between New Haven and New York, and as very quick turns are made at both termini, the service may be said to be more severe under these conditions than under the guaranteed conditions of purchase.

Comparative Steam and Electric Engine Mileage.—In obtaining an average for all electric locomotives of 212 miles, it is to be remembered that this was made for all classes of service, express, express-local, and local, and further that the mileages were made over three short terminal runs; namely, Stamford, Port Chester, and New Rochelle to New York, the distances being approximately thirty-four, twenty-six, and seventeen miles, respectively. Several engines made eight runs, two of them nine, and one ten. It is difficult to get an exact comparison for steam locomotive mileages. All of the electric engines are confined to one division, while the steam locomotives do interdivision service. However, using the records of the 1906 steam service for Labor Day and considering steam locomotives doing mileage in and out of the present electric zone, out of 117 locomotives the following record is to be noted: Ten made over 300 miles; twenty made between 200 and 300 miles; twenty-one made between 150 and 200 miles; thirty-four made between 100 and 150 miles; thirty-two made under 100 miles.

Thus with division limits double that of the present electric division, and with the additional advantage of interdivision runs, the electric mileage for this concrete case averaged thirty-four per cent better than the steam mileage.

THE ELECTRIFICATION IN ITS RELATION TO MATTERS OTHER THAN TRACTION.

Telegraph and Telephone.—Single-phase electrification affects telegraph and telephone systems whose wires lie parallel with and in close proximity to the railroad. The corrective for this disturbance has proved to be simple and not costly. Briefly described, it consists of compensating transformers whose secondaries are a part of the telegraph and telephone wires and whose primaries receive their voltage from pilot wires strung on the same cross-arms as those bearing the telegraph and telephone wires, and thus having impressed upon them the same voltage, by electromagnetic induction, as the telegraph and telephone wires. The transformer secondary voltage is approximately equal and opposite to the induced voltage on the telegraph and telephone wires and thus constantly compensates for it throughout all ranges of induction due to the single-phase wires.

Public Safety.—As no fatality to the traveling public has happened by reason of the high-voltage wires since the system has been in operation, this would indicate the safety involved in its construction. The catenary form of construction as applied to the suspension of the trolley wire virtually eliminates all danger of these wires falling. On the other hand, the feeder or by-pass wires are not suspended by messengers, and although the 300-foot spans used in this construction are not uncommon, it has been considered a wiser policy to reinforce all such spans which are above passenger platform stations. It may be of interest to state also that the scheme of reinforcement is not to cradle or place supplementary wires in connection with this span, but simply use a steel wire with a large factor of safety reinforced by copper for conductivity conductor and supported from the struts by insulators. The resistance to ground of this construction will be far in excess of the ordinary insulator used in the open construction with the steel wire connected to it in such a manner as to make impossible the burning of this wire in two in the case of the insulator breaking down.

Foreign Wires.—All electrifications are subject to foreign wire crossings. As in the case of suspension of high-voltage wires over passenger platforms, instead of using supplementary catenaries or cradles, the safer (and incidentally the cheaper) method of crossing is to use at the crossing heavier (and possibly guyed) poles, better insulation, and larger wires than are commercially necessary in the other parts of the foreign transmission line. High factors of safety with economy are obtained following this policy.

COMMENTARY.

Lightning Protection.—An ideal arrangement of catenary construction in relation to lightning protection would be to have the overhead messenger system grounded, and from it suspended by insulators a secondary catenary system, to which in turn would be attached the contact wires. Even in the New Haven case, where the overhead messenger system is not grounded, lightning has given but slight trouble. This is probably due to the very great number of grounded steel trusses and struts projecting above the electrified wires.

Grounds.—Structures supporting high-voltage insulators should be grounded. Particularly is this true of structures foreign to the railroad company, such as highway bridges. This arrangement insures a prompt response of the circuit-breaker apparatus, and carries out the good practice universally applicable, that the material supporting the insulator be grounded. This principle has application in wood-car construction. Positive grounds between Pintsch gas pipes and both car trucks should be made to avoid any arcs being drawn under the car body.

Many of our catenary bridges, of both the intermediate and anchor type, serve to support signals. Signal men have been entirely free from coming in contact with the high-tension wires, by the simple provision of grounded close-mesh screens interposed between the signal platforms and the high-voltage wires. The value of two grounds can be rated considerably higher than twice that of one.

Tell-tales.—Tell-tales in connection with an overhead system offer a peculiarly difficult problem. It is quite apparent that the pantagraph current-collecting device would get into either electrical or mechanical difficulties with the present form of tell-tales. We have experimented at some length in trying to produce an electrical horn that would be automatically sounded by an approaching train. There is nothing particularly difficult in getting the automatic action or in producing a noise. The superiority of the tell-tale over the horn, however, is that no matter how much noise the freight train is making, the tell-tale always notifies, while in the case of the horn should the freight train be making more noise than it, the notification is lost. A horn if used for this service should be a large one.

Train Lighting and Heating.—On account of the necessity of wiring for electric heating and lighting some 2,500 coaches, it seems reasonable to retain the present method and apparatus of heating and lighting the trains in the electric zone. To accomplish this it was only necessary to supply each electric locomotive with a small steam boiler used solely for train heating. The Pintsch gas system has been retained intact. Later, when the service is sufficiently extensive, all trains will be heated and lighted by electricity. All multiple-unit cars are to be heated and lighted by electricity.

Fatalities.—As has been pointed out, we have had several fatal accidents, due to men coming in contact with electrified wires. We are none the less concerned that in every instance they were men employed by the company. In each instance the accident was due to carelessness or violation of instructions, and most of the accidents occurred during the period of construction. The operating period has provided a less number of these unfortunate events, and the records today now seem to indicate that the future will be free from this most regrettable feature.

Cross-catenary Versus Bridge-bents.—The excellent results of a year's experience with cross-catenary construction in our Port Chester yard, where as many as ten tracks are spanned, is tempting encouragement for its application to main-line work.

Single Versus Double-catenary Construction.—Lack of operating data led the engineers of the New Haven road to take no chances with the overhead construction, and the double catenary was considered the safest.

Single-phase Operation.—The New Haven system provides that the volt manufactured in and leaving the doors of the power house, is the same physical volt that knocks at the doors of the locomotives. Thus the line is the single link that unites the power house and the locomotives. All such adjuncts as step-down transformers, synchronous converters, storage-batteries, and low-voltage distributing systems with their necessary attendant complement of help is dispensed with. The Cos Cob power house has the usual number of men for a station of its output, and the locomotives are operated by the electric locomotive engineer with the customary assistant present for emergency. This crew holds good for single or double-unit trains. An emergency repair train is the guardian of the line, attending to all matters pertaining to its repair and maintenance. Including the night and day crews of the emergency train the number of men employed to maintain the distribution system is nineteen. This covers about 100 miles of single track, including yards.

Conclusion.—In connection with the New Haven electrification I wish to speak of the privilege of association with E. H. McHenry and Calvert Townley. Upon Mr. Townley devolved the responsibility of decision as to the form of electrification selected. Neither the object nor the scope of this paper can include a description of the analytical course of procedure preparatory to the conclusion that the New Haven road would adopt the single-phase form of electrification. Suffice it to say that Mr. Townley's conviction to accept this responsibility was sufficiently strong to lay the foundation of this work. To E. H. McHenry, whose serious illness had prevented his filling the office of vice-president in charge of matters pertaining to engineering, fell upon accession to that office the responsibility of ratification or disagreement with the policy as set forth by Mr. Townley. That ratification is better written in the details of the electric zone itself, as in each department of power house, line, and locomotive may be seen the betterments due to his suggestion. To him is due the credit of the practical issue of this electrification.

This paper would, indeed, be incomplete did I not refer to the splendid courage and indomitable pluck of our contractors, who through a fire of criticism and business depression perseveringly stuck to their belief in the principles they were advocating. They can now have the satisfaction of viewing something begun and something finished; for while there may be many improvements to accrue to the alternating-current, single-phase system, the trunk-line principles have by them been laid and demonstrated.

After the reading of the paper Mr. Murray emphasized his belief in the single-phase, alternating-current system, and stated that it was with a good deal of pleasure that he saw among those present a number of noted engineers, who would undoubtedly contribute to the information available on this subject.

Mr. Ferguson said that the Institute owed to Mr. Murray an appreciation of the work he had done in thus frankly coming forward and stating the actual experience which he had had in the construction and operation of this untried and important undertaking. He called upon Calvert Townley, vice-president of the New York, New Haven & Hartford Railroad, who stated that he was strongly impressed by the radical way in which Mr. Murray had treated the subject. The nature and magnitude of the project under discussion emphasized the radical departure in Mr. Murray's methods. It was seldom that a man felt so sure that the beauties of the work which he had been doing would be so apparent that he could afford to call attention to only those points wherein he had failed initially, notwithstanding the fact that the ultimate working out had been eminently successful. Mr. Townley believed that now, five months after the complete substitution of electricity for steam, and while some of the improvements still have to be completed, the system has been demonstrated to be successful and well adapted to the service for which it was designed. It is an interesting fact that at the present time the electric service is less subject to delays and interruptions than was the steam service which it has replaced. The one radical thing that was done wrongly in the New Haven electrification, and which was really at the bottom of the major part of the difficulties that have been encountered, is that the electrification was not begun soon enough. Had more time been allowed for attention to minor details of equipment, and could work that had to be done under great pressure have taken its normal course, many of the troubles which can be traced to these facts would never have existed, and many of the defects which have caused delays to service would have been detected and remedied during the trying-out period instead of in practical service.

Mr. Townley took emphatic exception to Mr. Murray's expression that the company was not proud of the record made. Mr. Murray might say this in a spirit of great modesty, but Mr. Townley did not believe that any such statement was necessary. The company had reason to be, and was, proud of everything that had been done.

Mr. Townley endorsed what Mr. Murray had said in his paper concerning the Westinghouse Electric and Manufacturing Company, which was the contractor. This company's tireless, resourceful, prompt and cheerful co-operation with the engineers throughout the entire progress of the installation had contributed the essential features of its successful development, and the company was rightfully entitled to a full and frank acknowledgment. The keystone of the system was the locomotive. Without the single-phase, alternating-current motor the whole plan would become impossible.

In the locomotive a large part of the changes made were mechanical—not only mechanical changes to mechanical features, but also mechanical changes to electrical features. With the principal elements of the locomotive design, namely, the large gearless, twenty-five-cycle motors, there had been no trouble; their performance as to torque, commutation and capacity having been most gratifying. A feature of the locomotive design which Mr. Murray had passed over rather briefly was the flexible drive, whereby the armature of the gearless motor is wholly supported on and exerts its driving power through a set of spiral eccentric springs. Trackmen have frequently been appalled because electric locomotives are so much harder on track than steam locomotives of even greater weight, and it has now come to be a generally accepted conclusion that this is due to increased impact, because the armature dead weight is supported without cushion rigidly on the axle. The impact due to this additional dead weight is astounding. In the New Haven locomotives the method of mounting the armatures, obtaining the cushioned effect, exerting the full driving power of the motors, and compensating for the so-called varying torque thereof has been successfully accomplished. The results in improved track maintenance cannot fail to be of far-reaching consequence.

W. J. Wilgus raised the question as to what extent the engineer was morally justified in seeking renown by a brilliant dash into untried ways at the expense of travelers who pay their fare with the expectation of reaching their destination as nearly on time as the most practicable state of the art of transportation will permit. It seemed to him that experimental application of electrical apparatus to untried conditions belongs to unimportant localities, where the results of failure would not be burdensome, and that only the most reliable, well-tried methods should be used where the results of failure might be embarrassing.

B. G. Lamme said that he had been more or less intimately connected with the problems in the New Haven electrification. There were two parts of the system to which he had given a great deal of personal attention. These were the design of the alternating-current generators in the power house and the design of the main motors on the locomotive. The popular opinion, even among engineers, when the decision as to the use of single-phase, alternating current was first announced was that the greatest trouble would be found in developing the large gearless single-phase motors, and that the designing of the generators would be comparatively easy. The record made by the gearless motors, particularly for commutator wear, and the demonstration of the absolute value and longevity of the preventive leads were remarkable. At the present rate of wear on the commutators of the locomotives now in service it would appear that there was at least fifteen to twenty years' life in each one of them, and there had been relatively little sparking, even when developing two or two-and-one-half times full-load torque.

In the designing of the generators it was discovered that although the reaction which caused the difficulty was known, it had not been tried out to an extent which developed its most harmful effects.

Mr. Lamme described the phenomena which occasioned the pulsating armature reaction, and said that when the first rotor was built the structure was laminated as completely as mechanical conditions would permit. Upon testing the first machine it was found that there was local heating with heavy load sufficient to create hot spots which practically broke down the insulation. After trying several remedies it was decided to attempt to eliminate all pulsating reactions from the armature by putting a short-circuit winding on the rotor of such value that a large current could flow in it with but little loss. In order to maintain this condition indefinitely without overheating, it was necessary only to put enough copper on the armature so that the C^2R losses under the short-circuit condition were within the temperature capacity of the windings. A complete cage winding was placed on one of the rotors of the New Haven generators. This rotor had not been designed originally for this purpose and it was therefore difficult to adopt the most suitable proportions in this winding. The operation in practice, however, showed that the remedy was a practicable one. With the new rotors designed for the application of heavy cage windings all trouble disappeared. The fourth machine installed, which has a 4,260-kilovolt-ampere, single-phase rating, has a solid steel core, in the surface of which the copper-cage winding is embedded. As the service was increased and the whole electric service established, it became evident that there was a serious condition existing in the system which was indicated by extremely violent shocks to everything in case of a short-circuit. It had been calculated that the machines would give possibly six or seven times full-load current on the first rush in the case of a dead short-circuit, this dying down to possibly two or three times normal full-load current. Oscillograph tests indicated, however, that under certain conditions each machine could give at the moment of short-circuit almost 5,000 amperes on one phase, the normal full-load current being 340. With three machines in parallel this would therefore mean that approximately 15,000 amperes could be delivered momentarily. The oscillograph tests also showed that this short-circuit current would be maintained at almost its maximum value for a very considerable period, due to the cage winding on the rotors of the generators. Apparently this current at the first rush is not appreciably greater than on the machine before the dampers were added, but without the dampers the field was more quickly killed, so that apparently the breakers did not open until the current had fallen somewhat. With the heavy cage winding on the field structure, however, secondary currents were set up in this winding, tending to maintain the field strength, and thus the current rush was maintained at almost full value for possibly twenty to thirty alternations.

The experience with the windings of the generators indicated that they were being subjected to enormous forces in the end windings. As the machines could give about fifteen times full-load current momentarily on short-circuit, the force acting on these end windings would be 225 times normal, and in this case these forces were so great that it became a serious problem to devise a type of bracing on the end windings sufficiently rigid to withstand such a force. In the endeavor to support these windings against movement, probably the most complete system of bracing ever applied to alternating-current generators was developed and used on these machines; yet in spite of this there was evidence of movement at times.

It was decided to limit this short-circuit current to the value originally intended, namely, about six times full load. This was done by an unsaturated choke coil or impedance coil on the trolley side of each machine, which coil takes up a comparatively small voltage under normal operation, but in case of a short-circuit the electromotive force generated in it is sufficient to limit the current rush to less than half the value it would attain without this coil. With the installation of the choke coils the shocks on the machine were greatly reduced, so much so that further trouble from this source is not feared. An interesting point in connection with the use of the cage windings is that the apparent regulation of the system has been improved.

L. B. Stillwell said that the engineering world was fortunate in the fact that the New York Central Railroad and the New Haven Company had not adopted the same electric system. Such an opportunity to compare the possibilities and limitations of the direct-current system and the single-phase, alternating-current system is unprecedented, and, except in America, would be impossible. Unquestionably, each and every problem of electrification should be studied primarily with reference to local conditions, and such conditions might lead properly to the adoption of a system other than that which would be chosen to solve the more general problem of electrifying not only a terminal and limited suburban zone, but a railroad division or trunk line. The clear conviction and admirable courage of Frank J. Sprague in installing the multiple-unit system of train operation on the South Side road in Chicago was a most important advance in the art of railroading. The applicability of this system to trains requiring tractive efforts exceeding 50,000 pounds was demonstrated first in the New York Subway. The equipment of the New York Central had contributed to the demonstrated utilities of third-rail construction. The New Haven installation, substituting, as it does, 11,000 volts for 600 volts, and eliminating substations, opens the door to possibilities of electrification of railways over zones far beyond the reach of 600 volts, direct current.

A. H. Armstrong said that Mr. Murray was certainly entitled to the greatest praise for the frank presentation of the development period of the New Haven electrical installation. It was instructive to know how nearly the early claims which were advanced for the alternating-current systems have been fulfilled in the completed installation. The overcoming of difficulty after difficulty met with in operation is proof of the progress made in perfecting the complete electrical and mechanical equipment. In other words, the entire system, from the motors to the transmission, had been entirely changed from the original specifications, and this was what had been pointed out when the system was first announced. It was his experience that it costs fully twenty-five per cent more to construct an alternating-current, single-phase locomotive than one of equal weight equipped with direct-current motors.

He finds it hard to justify Mr. Murray's present enthusiasm for the system, which appears to him to be in many ways unsuited to the New Haven conditions.

Mr. Armstrong presented some figures which, he stated, showed that with approximately the same total weight a single New York Central locomotive unit has a capacity equal to two New Haven units, although the motors of the latter are cooled by forced ventilation, while in the New York Central motors natural ventilation is employed. Comparing the hauling capacity of the New Haven locomotive in handling a trailing load of 200 tons, he showed that the single New York Central locomotive was handling trains running from slightly over 400 tons to almost 700 tons. He said that each of these trains would have required at least two of the New Haven locomotives.

Mr. Armstrong said that he believed absolutely in the future of the alternating-current locomotive, but that it was his conviction that it was not adapted to the road upon which it was now being used.

N. W. Storer said that the publication of this paper should do much to silence the criticism which has been heaped upon the New York, New Haven & Hartford Railroad, and he paid a tribute to E. H. McHenry, who had borne the brunt of the storm without faltering in his determination to make the system a success. He took exception to some published reports which, he said, were written evidently without true knowledge of the capabilities of the single-phase motor. These motors have armatures, compensating winding and field all in series. They therefore have torque characteristics similar to those of a direct-current motor, in that, with a given current, the torque is the same for all speeds; that if the New Haven locomotive motors are taking 1,200 amperes each, that the tractive effort is 10,000 pounds, no matter whether the train is standing still or running at a speed of fifty-five miles per hour. The power-factor of the single-phase motor limits it only as it limits the maximum current that can be taken by it. Curves which he had plotted showed that the tractive effort at the one-hour rating for the New York Central motor is slightly more than double that of the New Haven. However, owing to the forced ventilation on the New Haven locomotive, its continuous capacity both in speed and tractive effort is higher than on the New York Central. This indicates that the New Haven locomotives will handle about the same weight of trains in express service as the New York Central, where the service is sufficiently continuous for the latter to get warmed up, even if the rate of acceleration is not so high.

H. P. Davis said that the problems encountered on the New Haven road are not simple nor within the scope of ordinary or established practice. Many conditions have arisen which it was impossible to foresee and guard against. Constructional difficulties, so long as they are not fundamental, do not affect the delay chain, except to the degree of time sufficient to investigate the troubles and to provide means to correct and eliminate them.

The paper was also discussed by E. B. Katte, Philip Torchio, Prof. C. L. de Muralt, William McClellan and Doctor Steinmetz.

Doctor Steinmetz said that his conclusion, from the evidence and data now available, was that those railway problems which cannot be handled by direct current must be solved by the alternating-current motor, and, as we know now, can be solved by the alternating-current, single-phase motor. But where direct current as well as alternating current can be used, the higher weight efficiency—that is, the greater draw-bar pull per pound of motor weight—afforded by the direct-current motor necessarily makes this motor preferable from the electrical engineer's point of view. It is interesting, then, to note that in those railway problems which can be handled by alternating-current motors as well as by direct-current motors, the decision whether one or the other type of motor shall be used has shifted from the electrical engineer to the railway engineer or the railway manager, and is determined by the economical question whether higher weight efficiency—that is, higher draw-bar pull per pound of motor weight—and at least at present a somewhat lower reliability of service are sufficient compensation and should be sacrificed for the possibility at some time of being able to extend the same system of operation over those parts of the road which cannot be operated by direct current, and over such other roads where direct current cannot be used; or whether the higher weight efficiency of the direct-current motor and present greater reliability of service compensate for the possibility that at some future time we may have to replace the locomotive equipment or change locomotives at the end of the direct-current zone and the beginning of the alternating-current zone.

After some desultory discussion the meeting was adjourned.

Northwestern Electrical Association.

The annual meeting of the Northwestern Electrical Association will be held at the Hotel Pfister, Milwaukee, Wis., January 20 and 21, 1909. An address will be made by Prof. B. H. Meyer, chairman of the Railroad Commission of Wisconsin, and discussion will be had on the rulings of the Commission, on tungsten lamps and other timely subjects.

QUESTIONS AND ANSWERS.

Use of Bells on 220-volt Circuit.—I have a number of bells that I wish to connect to a 220-volt direct-current circuit. They are now connected to dry cells, that I want to discard. What kind of apparatus must I have? I want something simple that I can make myself. Can ordinary dry batteries be recharged on direct current?—J. A. B., Chicago.

Substitute the 220-volt circuit with a 220-volt incandescent lamp in series for the dry batteries as the source of current. The lamp reduces the voltage at the bell to approximately what it is designed for. To prevent arcing at the bell contacts, a high-resistance shunt should be connected across them; a small coil of German silver wire, wound non-inductively, will suffice. Dry batteries cannot be recharged with any practical success, as the chemical action occurring therein is reversible with only a very low efficiency. When such a cell is exhausted it is much cheaper to throw it away and buy a new one than to expend any effort to recharge it.

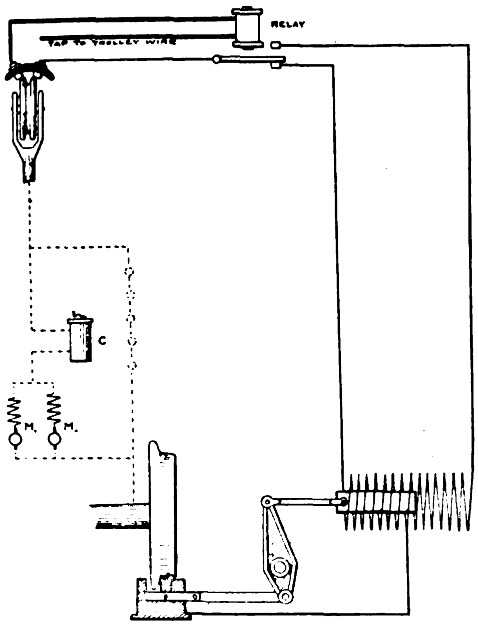
Rating of Open and Enclosed Motors.—A number of shunt motors that I have noticed are rated at so many horsepower and so many amperes "closed" and so many horsepower and amperes "open." What is the meaning of these terms as regards such motors?—M. A. L., Peoria, Ill.

When a motor is operated with the ordinary open frame there is much better ventilation of its windings than when the motor is more or less housed in or enclosed. In the latter case a smaller current will produce the same temperature rise of the conductors than a considerably larger current produces in an open motor. For this reason some manufacturers have a lower nominal rating for their "enclosed" motors than they have for the same motors in an "open" framework.

Automatic Track Switch.—Kindly explain the operation of the automatic street-car switches used on the South Side, as, for instance, the one at 18th Street and Wabash Avenue.—H. D., Chicago.

About sixty feet back of the track switch there is installed on the trolley wire an inverted trough with separate side contacts adapted to be engaged by the rims of the trolley wheel. The trolley wire is carried over this trough and is connected with one of the contacts through the coil of a relay mounted vertically on the trolley pole at the curb line. The contacts on the opposite side of the trough connect to the armature of the relay through a high resistance and fuse (not shown in the accompanying diagram). To the contacts engaged by the relay armature are connected the terminals of the two half windings of a solenoid, the core of which acts on the tongue of the track switch through a lever, the whole being mounted in a sealed box embedded between the rails.

When the motorman, in approaching the switch, allows the car to coast with his controller "off," the trolley wheel connects the opposite contacts in the trough, establishing a circuit through the relay, the high resistance, the armature of the relay, the lower contact and half the solenoid winding to ground. This current is not strong enough to actuate the relay, and therefore its armature remains on the lower contact, sending the current through the left half of the solenoid, and moving the switch to one side. When the motorman approaches the switch with the controller "on" the first or second



AUTOMATIC TRACK SWITCH.

point, the current through the relay is much stronger than before, since it finds a path of low resistance through the motors; the armature is therefore drawn up, and this sends current through the right half of the solenoid and throws over the switch. A strong spring in the track box aids in throwing the switch and holds it in locked position. This type of automatic switch is called the Chatham electric track switch.

Small Gasolene-driven Lighting Plant.—(1) In reading the article on "Lighting Country Homes by Private Electric Plants," that appeared in the Western Electrician of October 24, it was not clear to me whether the lights can be run directly from the dynamo while charging the battery. (2) If a person had a 110-volt dynamo, could he not use that by cutting in proper resistance while charging the battery? (3) Is it good policy to put the dynamo on a concrete foundation without putting a layer of wood between the machine and the foundation? (4) With the size of engine mentioned in the article (two horsepower) would it be necessary to have heavy fly-wheels on the engine to give steady speed or would a small marine engine do?—B. E. M., Seattle, Wash.

(1) The diagram of connections, shown in Fig. 5 of the article referred to, does not provide for running the lights from the dynamo when charging the battery except by closing switch s_2 while s_1 is down. During the battery charge the dynamo voltage is thirty to forty volts; this is pretty strong to put on twenty-five-volt lamps. The plant has been designed to be of as simple design as possible, therefore auxiliary apparatus to permit the object desired has not been contemplated. However, a rheostat of low resistance and large current capacity could be inserted in the lighting circuit above s_2 to cut the voltage down to twenty-five volts; it would have to be adjusted from time to time as the generator voltage was raised and the number of lights changed. (2) The use of a rheostat with a 110-volt dynamo to supply twenty-five-volt lights or a thirty to forty-volt battery is not advisable, as there would be too great an energy loss in the rheostat; in fact, two or three times as much energy being converted to heat as would be usefully employed. The rheostat, too, would have to be quite large and expensive in first cost. (3) A dynamo can be put down directly on the foundation if it is well bolted down to make it free from the engine vibrations. If the dynamo and engine are on the same foundation, a layer of wood would tend to deaden the vibrations. (4) Fairly heavy fly-wheels should be provided to give uniform speed. For this service specially-designed engines are now on the market.

Construction of Condensers.—Certain condensers used in wireless telegraphy have, I have noticed, a dead or disconnected conducting plate inserted midway between the active conducting plates. What effect does this arrangement have on the capacity of the condenser?—F. D. M., Uvalde, Texas.

The capacity of a condenser varies inversely as the square of the distance separating the plates. Thus if the dielectric and area of the plates remain the same and we are to halve the distance between them, the capacity of the condenser will be fourfold its original value. Again, two similar condensers connected in series have a combined capacity half that of either. It is evident that in the case of two "active" plates between which is a free or disconnected conducting plate, we have two condensers in series, either one of which would have four times the capacity of that between the two outside "active" plates, since its plates are at only half the distance. Thus the net increase in the capacity of the condenser has been to double its effective capacity, without decreasing the actual dielectric distance between the connected plates, which determines the breakdown point of the condenser.

BOOK REVIEW.

"Heating and Ventilation," by Charles L. Hubbard. Chicago. The American School of Correspondence. 7x10 inches. 221 pages. Cloth. Supplied by the Electrical Review and Western Electrician for $1.50.

This volume was designed and written for purposes of self-instruction and home study. For this reason the language, and the explanations of the various apparatus and processes followed in heating systems are simpler than is usually the case in text-books. The book is divided into three parts, entitled, respectively, "Systems of Warming;" "Indirect Steam Heating," and "Vacuum Systems."

The first part describes the various systems in use, including the common hot-air furnace and direct steam-heating systems. This part is rather elementary in character and presents numerous illustrations of forms of apparatus, methods of piping and details of construction. The calculations necessary for the proper design of a heating system, both as to heating surfaces and the radiating surfaces of rooms or buildings, are explained in a clear and simple manner.

Part II, dealing with indirect steam heating, hot-water heating and exhaust-steam heating, covers much the same ground in relation to these systems as does Part I, in regard to the systems there discussed. The same may be said of Part III, dealing with vacuum heating. Temperature regulation is described in this section, and a short note is appended on the care and management of apparatus. The book contains much information of value to the student, although he is required to take much for granted. Information is not given as to the derivation of the rules or laws laid down in the work, and the student will have to go to other sources to find them. However, these rules and laws, together with the tables accompanying them, are conservative in their values and well on the side of good

Thirteenth Annual Meeting and Banquet, December 11.

The thirteenth annual meeting and dinner of the Electrical Trades Association of Chicago was held in the banquet hall of the Chicago Athletic Association on Thursday evening, December 11. An excellent menu was discussed, Thomas I. Stacey, treasurer of the Electric Appliance Company, acting as toastmaster. Addresses were made by B. E. Sunny, president of the Chicago Telephone Company; Albert H. Elliott, secretary of the Pacific Coast Electrical Trades Association; James J. Barbour, of the Chicago Bar; A. O. Kuehmstedt and F. M. Pierce. William A. Browne, president of the association, introduced the toastmaster. During the progress of the banquet a number of old songs were sung, led by the master chorister, Harry R. Parsons.

A very pleasant feature of the dinner was the rendition by A. O. Kuehmstedt, in a fine tenor voice, of an original song to the tune of "Illinois," interpolating a sketch on "Mr. Vose." Toastmaster Stacey read a poem which he had composed himself as a tribute to James Wolff, National Representative of the association, but who was unfortunately absent. Those present insisted upon hearing Mr. Stacey's effort, which was received with the greatest enthusiasm:

Whose "glad hand" is always out
With welcome warm, and hearty shout?
Sunny Jim, Sunny Jim.

Who has the car that always motes
As many friends around he totes?
Sunny Jim, Sunny Jim.

Who has the tickets to the show
Where willing buyers gladly go?
Sunny Jim, Sunny Jim.

Who is it shows the boys the town
When strictly business brings them down?
Sunny Jim, Sunny Jim.

Who is it travels "down the line,"
But comes back smiling fresh and fine?
Sunny Jim, Sunny Jim.

Who has the lines that always sell,
And their good points, who knows so well?
Sunny Jim, Sunny Jim.

Who is it takes the orders in
When others say that trade is thin?
Sunny Jim, Sunny Jim.

Who is it smiles and winks his glim
When rivals try the axe on him?
Sunny Jim, Sunny Jim.

Who is it brings about a truce
When all the rest would raise the deuce?
Sunny Jim, Sunny Jim.

Who is it smooths the troubled way
When others say there's "hell to pay?"
Sunny Jim, Sunny Jim.

My song is sung—My muse is dim,
Step lively, boys, the treat's on him.
Sunny Jim, Sunny Jim.

The report of Secretary-Treasurer Frederic P. Vose showed that the present membership is 201, as compared with 188 a year ago. There were handled during the year 4,315 listings, as compared with 3,106 last year, making a total of 19,680 since the organization of the association in 1896. Last year there were 3,318 settlements effected. The Executive Committee had declined to act on only thirty-four complaints because of disputed accounts.

The election of officers resulted as follows: President, William A. Browne, M. B. Austin Company; vice-president, F. M. Pierce, Manhattan Electrical Supply Company; Executive Committee (to serve until 1911), H. R. Parsons and F. M. Horton; national representative, James Wolff.

Wilmington Electric Company Awards Prize of House-Wiring.

The Wilmington (Del.) City Electric Company recently held an exhibition at its salesrooms and offices, 603 Market Street, and during the exhibition each of the callers at the salesrooms was requested to register. At the conclusion of the registration the names were all placed on small cards, put into a box and well shaken. J. Berndt, who is in charge of the specialty department, for the company, stepped to the door and called in a small boy from the street, and the lad drew three of the checks, the third to be the one bearing the reward, which was tendered to G. Brown, 510 East Ninth Street.

As a result, Mr. Brown will have the privilege of having his house wired to the extent of $25 worth of material and work. Had his home been already wired he would have had the privilege of selecting the best table, or standing lamp in stock in the store. The award was conducted in the front window of the establishment, and the spectators witnessed the action with interest.

Electrotherapeutic and Radiology Convention.

A convention devoted to the medical and scientific professions will be held from July 6 to July 9, next year, at the University of London, England, to discuss the most recent developments in electrotherapeutics and radiology. Exhibits of apparatus and appliances will be made, and the object of the conference and exhibition will be to attract the attention of the medical profession generally to the developments of these branches of science. The organizing secretary is Ernest Schofield, 11 Chandos Street, Cavendish Square, London, W. C., England.

HISTORY OF AXLE LIGHTING.[1]

BY W. L. BLISS.

Axle lighting is as old as any form of electric lighting ever suggested for or experimented with upon railroad cars. It is older than the head-end steam system, and dates back to within less than half a dozen years of the commercial births of the incandescent lamp and the storage battery, while the first practical and commercial dynamo is not more than a dozen years older than the first proposition to light a railroad car with an axle-light system. It is the intention of the writer, not so much to compile a thoroughly accurate chronological record of this art, nor to discuss in detail the various schemes that have been brought forth from time to time, but to deal more particularly with the development of methods and principles, leaving the minor details to be discovered and discussed by those who are interested in the subject.

The patent history of axle lighting is quite voluminous, several hundred patents having been issued to various American inventors alone for their improvements in axle-lighting apparatus, while numerous foreigners have protected their inventions in the United States. The earliest English patent that the writer has been able to obtain upon this subject is No. 5316 of 1881, issued to Richard Laybourne, in which the broad principle of a generator driven from a car axle and used in connection with incandescent lamps and a storage battery, was applied to the lighting of a railroad car. As he names the four essential elements of any axle-lighting system, this patent certainly must be regarded as fundamental.

As far as the writer has been able to discover through the records of the Patent Office, the oldest man in the axle-light business who is still actively engaged in this work, is Morris Moskowitz. The next oldest, in point of years devoted to this art, is Patrick Kennedy, while the writer believes that he himself is entitled to third place.

The writer believes that the first incorporated company to exploit axle lighting in the United States was the National Electric Car Lighting Company, of which Morris Moskowitz was the electrical engineer. This company is no longer in existence, but has been absorbed by the Consolidated Railway Electric Lighting and Equipment Company, which is still very much in existence and which has absorbed and taken over a number of companies identified with axle lighting. Mr. Kennedy began his active career with the American Railway Electric Light Company, which likewise has been absorbed by the Consolidated Railway Electric Lighting and Equipment Company. The writer began his stormy career, not with any company, but between two companies, the American Railway Electric Light Company and the Lewis Electric Company. Both had their births in the factory of the Riker Electric Motor Company, of Brooklyn, N. Y., where the writer was employed in the humble capacity of chief enginer, head draftsman, office boy, guest entertainer and general utility man. These were the early days of axle lighting. Many were the schemes propounded and many were the disappointments encountered. But with these small beginnings, the writer believes that today we are on the verge of a great era of axle lighting, and that many of those who were pioneers in this early work and assisted in its development will yet witness the triumph of this wonderful art. It has been fascinating to all those who have engaged in it, and while enormous sums of money have been spent in its development without corresponding returns, the writer believes that the day is not far distant when those who have created and developed this industry will reap the benefit of their exertions.

As mentioned in the patent history above, the essential elements of an axle-lighting system are a revolving axle, a generator driven thereby, a set of storage batteries and some incandescent lamps. This sounds very simple and easy of application, but twenty-eight years have elapsed since this proposition was first propounded. In all that time, axle-light apparatus has not become as standard as automobiles, although it is probably more standardized than flying machines. It was early seen and appreciated that more apparatus would be needed than the four elementary pieces already mentioned.

Beginning with the axle, there has probably been quite as much ingenuity and both useful and useless effort expended upon methods of driving the generator as there have been upon any other parts of the system. The earliest practical method of driving the generator was by means of a belt, the generator being mounted directly upon the body of the car. This method was applicable and feasible in England, where cars with rigid trucks were almost exclusively the rule, and even today this method continues to be the favorite in England on rigid truck cars and has even been extended to swinging or bogie-truck cars in England, the United States and a great many other countries. The body-mounted belted generator was certainly the pioneer, and it has not been entirely supplanted at this date. All sorts of methods have been devised for maintaining the tension of the belt. Idlers of all kinds, double, single and multiple, have been suggested and experimented with. All kinds of supports and mountings for the generators have been developed. They have been pivoted on the top, pivoted on the bottom, placed on rollers and supported on slides, while means for producing resilient tension have consisted of spring, gravity, compressed air, magnetic, vacuum, hydraulic, centrifugal and various other kinds of devices. We also find that it has been the intention of some inventors to allow their belts to slip, others to keep them from slipping, while most inventors have generally succeeded in developing a method of maintaining the tension on their belts that has acted exactly the opposite from what they intended. In most cases where it was intended that the belt should slip, it has generally stuck fast and driven with great vigor. In cases where it was intended that the belt should stick, it has slipped most provokingly.

It will be impossible to relate the various troubles that have developed in simply the means for maintaining belt tension. To obviate the difficulties in maintaining proper belt tension, schemes have been developed whereby the tension could be adjusted by an attendant in the car. Automatic devices for varying the tension of the belt to compensate for wear in bearings, stretch in the belt, etc., have been designed which have contained as much machinery in the shape of motors, worms, gears, limit switches and the like, as would be found in a complete and modern axle-light equipment.

When we consider, however, the question of driving the axle generator in connection with the problem of taking care of its polarity, the task of the historian becomes Herculean. To describe the double-belt systems, using open and crossed belts, the shifters for changing from one belt to the other, the ratchet schemes for allowing one belt to drive in one direction and the other in the other direction; to describe the countless methods of maintaining constant speed by

[1]Abstract of a paper read before the Association of Car Lighting Engineers at the convention in Chicago on November 16.

means of belt combinations with cone pulleys of the Evans type, flyball governors, revolving oil tanks, sliding collars, drums, worms, back gears and sundry similar schemes, would occupy too much time and be altogether uninteresting.

There have been one or two fairly good propositions brought forward for maintaining motion of the generator after the train comes to a stop. The best of these schemes, it seems to the writer, was that employing an air compressor driven from the axle, which stored air in a tank and in turn operated an air-driven engine connected to the generator. The efficiency of such a system could not be high, but it at least has the virtue of being a means of storing energy without employing a storage battery. While schemes of this kind evoke perhaps a smile, they are really no farther from being adopted by practical railroad men than many of the other apparently more feasible schemes that have been advanced from time to time.

The early methods of gear drive were all designed to overcome the difficulty that arose from the fact that the distance between the center of the axle and the center of the generator continually varies unless the generator frame be journaled upon the car axle in the manner adopted in all modern street-railway motors. The only parts of a railroad truck that maintain any kind of a fixed relation with the axle are the journal boxes and equalizer bars, and even these do not maintain a strictly constant relation. The equalizer bars were early employed to secure the bearings for a gear which might in turn engage with a gear upon the axle, and from the gear mounted upon the equalizers, a connection was carried to the generator, either inside of the car or upon the track. The writer's earliest experience with an axle generator was with one of this type wherein the generator was located inside of the car above the truck and a telescopic shaft with two universal joints transmitted the motion from the gear mounted upon the equalizer bars to the generator inside of the car. Complicated as this construction may seem, it is exactly, in all respects, the standard form of transmission found in the best automobiles today, and there isn't any real reason why a system of transmission such as is employed on automobiles should not be used for operating an axle generator. Developments have not taken that trend, and it is doubtful whether anything further will be developed in this line.

Several other types of direct gearing have been developed and experimented upon. Probably the best known of these methods were the false-sleeve system of Biddle and Kennedy, and the hollow-shaft system of the writer. Both of these systems aimed to accomplish the same purpose. In the former device the false sleeve was mounted upon the axle, and upon this sleeve the proper journals were turned and the proper gear seat finished for making a veritable street-railway mounting, the idea being to take the rough axle as it was found and leave it in the same condition, no tooling or machining of the rough axle being permissible. It is the writer's belief that, if the railroads had met the problem of axle lighting in a more liberal manner and had had special axles prepared, as in street-railway practice, axle lighting would have been developed, so far as the generator is concerned, a great deal earlier, although it must be said that generators mounted inside of the truck have the great disadvantage of inaccessibility, and steam railroads are not prone to furnish inspection pits for facilitating the care and inspection of axle-light apparatus.

The direct-gear system, devised by the writer, differed from that of Biddle and Kennedy in that none of the weight of the machine was carried upon the axle. The hollow shaft surrounded the axle, but did not touch it. Motion was communicated by a flexible though positive connection from the axle to the hollow shaft, and upon the hollow shaft was mounted a gear which drove the generator pinion. The bearings for the hollow shaft had to be considerably larger than in the case of the Biddle and Kennedy arrangement, but the machine had the advantage that it rode upon the truck frame and was free from the direct shock communicated by the axle in the Biddle and Kennedy device. Both these arrangements were developed on a commercial scale and went into actual service; it is the writer's belief that a few of them can be found in commission today.

[To be concluded.]

New York State Public Service Commission Notes.

The report of the gas-meter tests by the New York Public Service Commission for November shows that during that time 30,126 meters were tested, of which nine per cent of the meters complained of were correct, fifty-seven per cent fast and thirty-four per cent slow. Of the total fast meters, thirty-six per cent were two per cent or more fast; and of the slow meters, ten per cent were more than two per cent slow, leaving fifty-four per cent within two per cent of normal.

The report shows that forty-seven electric meters were tested, of which 76.5 per cent were within four per cent of normal, 8.5 per cent were four per cent or more slow, and fifteen per cent were four per cent or more fast.

The Public Service Commission has decided to requisition the Board of Estimate and Apportionment for $987,500 to defray the expenses of the Commission for the calendar year 1909. This compares with $1,095,000 for the present year.

The Public Service Commission, Second District, has issued an order to all railroad companies, requiring them to file with the Commission, on January 1, a statement as to the methods employed by corporations respecting the transmission, filing, arrangement, and the checking at stations of schedules showing rates, fares and regulations applying to the transportation of passengers and property.

Comparison of the Working Costs of Small Arc Lamps and High-Candle-Power Osram Lamps.

A recent number of the *Elektrotechnische Zeitschrift* contains an article by H. Remané, dealing with this subject. It appears that the Auer Company is turning out osram lamps of 200, 300 and 400 candlepower, suitable for burning on circuits whose voltage lies between 110 and 130 and between 200 and 270 volts. These lamps have a life of about 800 hours, the candlepower diminishing five or six per cent in that time. The ratio of the mean hemispherical illumination to the mean horizontal illumination is about 0.82, and the efficiency is about 1.33 watts per candlepower. These lamps, when used for interior lighting, are fitted with a reflector, and when employed outside, with both a reflector and clear-glass globe, the figures for efficiency then become 0.98 and 1.05 watts per candlepower, respectively. The results obtained of the cost of energy with different types of lamp and by different observers, taking the cost of current to be four-and-one-half pence per unit, are given in the tables below:

Table I.—Consumption in Watts per Candlepower for Direct-Current Enclosed Arc Lamps.

Electricity Versus Steam for Trunk-Line Operation.

In the New York *Times* of November 29, William J. Wilgus, under whose direction the electrification of the terminal zone of the New York Central & Hudson River Railroad Company was inaugurated and carried well to completion, has written interestingly on the probability of the general electrification of main lines. Mr. Wilgus says:

"While many of those who are engaged in the practical application of electricity to the art of transportation naturally hesitate to prophesy on what the future may bring forth, they may at least venture the expression of a desire for that which they would like to see accomplished in the field of invention.

"The successful substitution of electricity for steam in terminals in large cities has stimulated the curiosity of the public as to the rapidity with which the change will spread, until that well-tried friend of eighty years' standing, the steam locomotive, will be relegated to the museum. Statements have been made that ten years will see this revolution accomplished, but it is perhaps needless to say that they are groundless.

"The early electrificaton of steam railroads in great centers of population is inevitable, because the demand of the public for the removal of the disagreeable features incident to the use of the steam locomotive is reinforced by the benefits that will accrue to the railroads in increased earning capacity and the possibilities of economies that will at least tend to offset the interest charges on the cost of the change. Away from the large cities the prospects for the eclipse of the steam locomotive are very remote, pending the perfection by the inventor of devices that will substantially reduce the cost of installation and thereby minimize the burden of additional fixed charges. For instance, with the direct-current third-rail system the cost of distribution of electric power is large owing to the need of expensive substations for the conversion of high-pressure alternating current, so well suited for economical transmission to the low voltage direct current for working purposes in the third rail and motors. Attempts to escape this expense by the use of the overhead alternating-current system have not been entirely successful where adopted on trunk lines, as the saving in substations has been offset by the greater weight and cost of electric locomotives, and by unreliability of operation.

"This question of comparative cost and reliability is the real point at issue in the warfare that has been hotly waged for the past five years over the relative merits of these two systems. Until this dispute is definitely settled no great progress can be expected in the general application of electricity on steam railways.

"Apart from the substantial reduction in the costs of installation of electricity on steam railroads that will follow a satisfactory solution of the problems of the rival system there are a number of other opportunities for advance in the art. For instance, the development of waterpowers and the utilization of cheap fuel at the mines, combined with an extended permissible radius of transmission, will all tend to lower the costs of current to prospective users at remote points. Then, too, improvements are constantly being made in power station design by minimizing the losses accompanying the conversion of fuel into energy. The simplifying of signal systems so as to reduce the cost on electrified steam railways is also an important item. The necessary safeguards for protecting the movement of heavy trains at short intervals on electrified trunk lines are now very expensive and one of the principal handicaps to the widening use of electricity.

"The high first cost and the expense of maintenance of batteries now preclude their more extensive use for insuring reliability of train service and lessened cost of operation. Their improvement will not only overcome that obstacle, but will also make more practicable the use of electric locomotives that will be non-dependent on third rails and overhead conductors, particularly in yards and terminals.

"It is hoped that in the early future the question of the preferential electric system for adoption on steam railways will be conclusively settled, and that improvements in the generation, transmission and conversion of current, and in signals and rolling stock, with due regard for safety and reliability, will largely reduce the cost and increase the efficiency of electrical appliances. When that time comes the steam locomotive may well look to its laurels."

Mr. Wilgus is chairman of the Board of Advisory Engineers of the Detroit River tunnel of the Michigan Central Railroad, and is prominently identified with a number of other large industrial organizations. He is the head of the Amsterdam Corporation, which is seeking powers to build and operate an extensive system of electrically-operated freight tunnels, serving the water-front and warehouse districts in New York city.

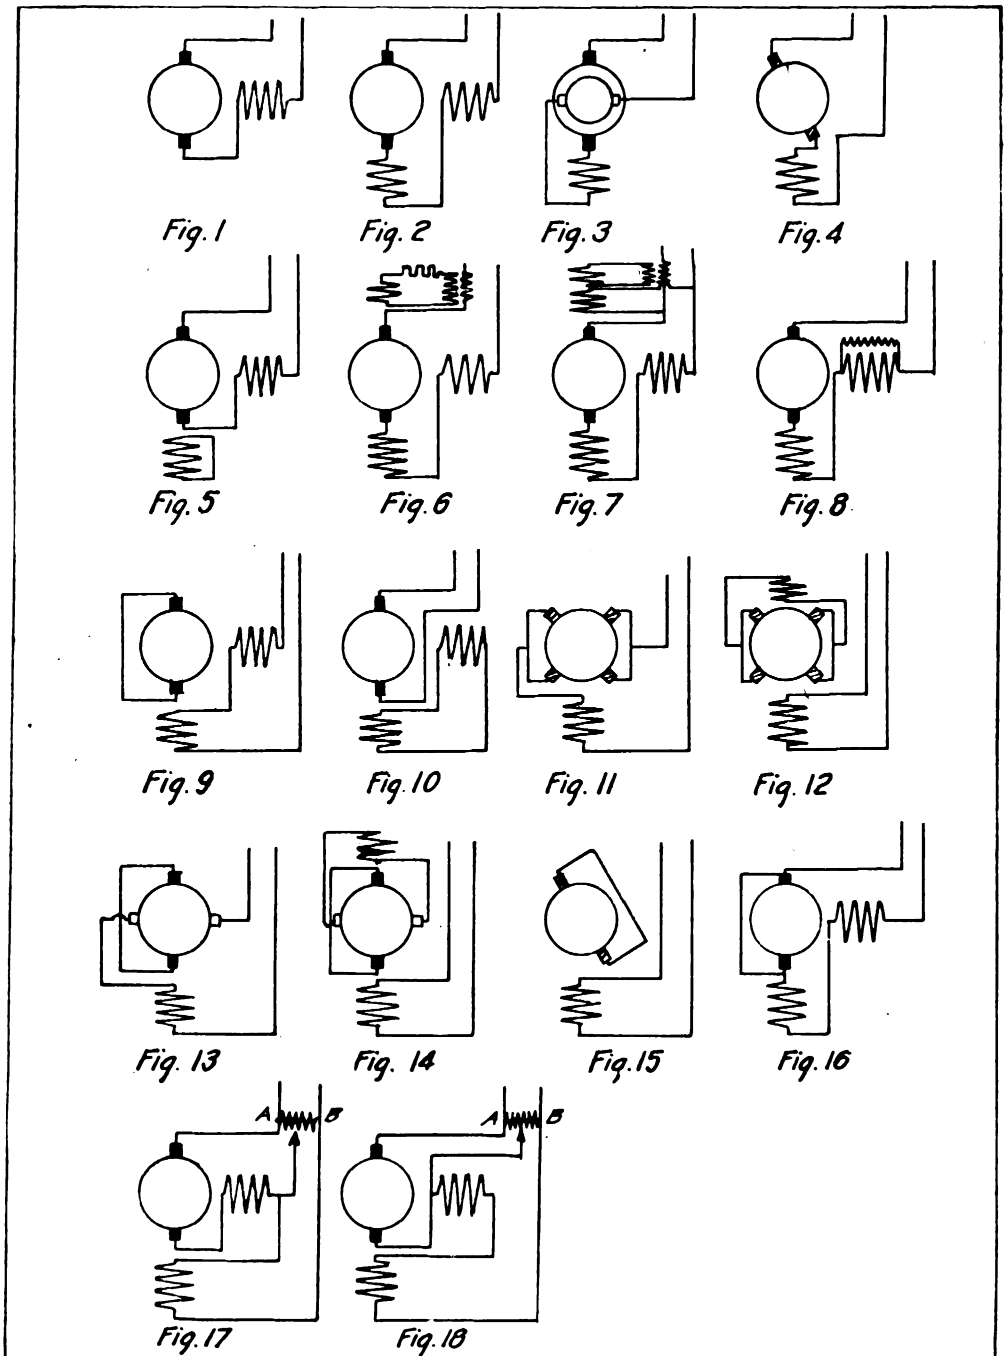
Armour Institute Branch, American Institute of Electrical Engineers.

On December 3 the Armour Institute of Technology Branch of the American Institute of Electrical Engineers held a well-attended meeting, the topic of the evening being the presentation and discussion of a paper by Tracy W. Simpson on "The Alternating-Current, Single-Phase, Commutator Motor."

A large number of commutator motors of various forms, as developed both in this country and in Europe, were described in considerable detail and a brief explanation made of the principle of design of each type. Each type of motor was studied from the standpoints of commutation of load component of current, commutation of short-circuit component of current, rotor reaction, power-factor, torque per volt-ampere, and ability to operate on direct current.

The various methods of improving operation along these lines, as exemplified in the various types of motors, were considered in some detail. In addition to explaining many of the complex phenomena of operation, the new method of improving power-factor, consisting of an auxiliary winding on the exciting field connected as a shunt across the mains, was illustrated by means of vector diagrams. This method is due to Osnos, of the Felten and Guilleaume-Lahmeyer Werke. Attention was called to the superior operating characteristics of the series repulsion motor as well as to the general improvement attainable by motors having both stator and rotor power. It was stated that this motor compared unfavorably with the compensated series type employing resistance leads for long continued overloading at starting, such as would be occasioned by the wheels of a locomotive being locked from too heavy trailing load.

A very interesting set of diagrams, reproduced herewith, was shown of the circuits of most of the motors described. All the diagrams apply to two-pole motors with uniform gap reluctance. The energy axis is shown vertical, the exciting axis horizontal. In the brief synopsis of the various diagrams given below the following abbreviations are used: "Compensated"—in which the pulsating rotor reaction along the energy axis is completely damped; "neutralized"—in which the electromotive force due to the alternating field in the short-circuited coil undergoing commutation is balanced; "rotor power"—that introduced into the



CIRCUIT DIAGRAMS ILLUSTRATING MOTOR CHARACTERISTICS.

rotor by conduction; "stator power"—that introduced into the rotor by induction from the transformer winding on the stator; "rotor field"—exciting field from the rotor, the flux from which is not compensated on the exciting axis; "stator field"—exciting field from the stator coils, fed either by conduction or induction; "series motor"—having the field in series with the energy current of the rotor; "repulsion motor"—having stator power and hence two fluxes of ninety degrees space and time phase and of comparable magnitudes.

The first four diagrams relate to direct-current series motors, since an understanding of the action of these types is useful as an aid to analyzing their alternating-current counterparts and derived forms.

Fig. 1.—Stator field, compensated by changing reluctance from uniform value, i. e., projecting poles not neutralized.

Fig. 2.—Stator field, compensated, or neutralized and compensated, by counter field on energy axis.

Fig. 3.—Rotor field, compensated, or neutralized and compensated.

Fig. 4.—Rotor field, operates due to partial compensation along energy axis.

The following six diagrams illustrate common types of alternating-current series motors; the names given are those of the inventor or manufacturer:

Fig. 1.—Stator field, compensated by high reluctance along energy axis; Finzi.

Fig. 2.—Stator field, conductively compensated; Lamme (Westinghouse Electric and Manufacturing Company).

Fig. 5.—Stator field, inductively compensated; Eickemeyer.

Fig. 6.—Stator field, conductively compensated and neutralized; Oerlikon Maschinenfabrik.

Fig. 7.—Stator field, conductively compensated and neutralized; Siemens-Schuckert Werke.

Fig. 8.—Stator field, conductively compensated, resistance shunt to field; McAllister.

The following seven diagrams illustrate various types of alternating-current repulsion motors:

Fig. 9.—Stator field, stator power, conductively compensated; Atkinson.

Fig. 10.—Stator field, rotor power, inductively compensated, not a true repulsion motor.

Fig. 11.—Rotor field, stator power, conductively compensated; Latour (Felten and Guilleaume-Lahmeyer Werke).

Fig. 12.—Same as Fig. 11, for high voltage.

Fig. 13.—Rotor field, stator power, conductively compensated; Winter-Eichberg (Allgemeine Elektrizitäts Gesellschaft).

Fig. 14.—Same as Fig. 13, for high voltage.

Fig. 15.—Rotor field, stator power, conductively compensated on energy axis, original repulsion type; Thomson.

The last three diagrams show motors having both stator and rotor power.

Fig. 16.—Stator power by over-compensation, excess current thus occasioned is short-circuited; rotor power by series method (Fig. 2); Alexanderson type at starting; General Electric Company (1907).

Fig. 17.—Stator power by action similar to Fig. 9 if field of latter be in rotor circuit, this is only action with moving contact at A; rotor power by series method similar to Fig. 5, this is only action if moving contact is at B; Alexanderson type at running points; General Electric Company (1907).

Fig. 18.—Combination of Figs. 9 and 10, depending on position of contact, stator power only with contact at A; rotor power only with contact at B; both actions repulsion method; Felten and Guilleaume-Lahmeyer Werke.

There were also described several motors having constant speed characteristics, such as the Wagner, Schüler and Fynn types. These are not illustrated in the diagrams, however.

ALTERNATING CURRENTS AND THEIR APPLICATIONS.

BY EDSON R. WOLCOTT.

CHAPTER II. (PART II.)—ROTATING MAGNETIC FIELDS.

ADVANTAGES OF ROTATING-FIELD ALTERNATORS.

From the point of view of simplicity of construction and economy of operation,

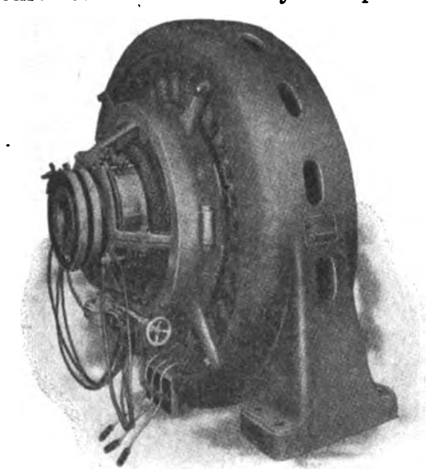


FIG. 48.—ALTERNATOR WITH DIRECT-CONNECTED EXCITER.

there are advantages in rotating the magnetic poles rather than the armatures of alternators. Better mechanical construction, as well as more perfect insulation of the armature windings, is attained in this way, and no collecting rings for the generated current are necessary.

This type of alternating-current generator has almost entirely displaced the revolving-armature type, except in the case of some small alternators. The large machines, of which an example is shown

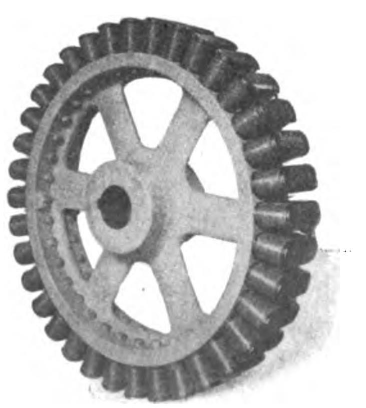

FIG. 49.—REVOLVING FIELD STRUCTURE.

in Fig. 47, are invariably of this type. The alternator illustrated is a 6,600-volt generator, to be connected directly to the prime mover. It has a capacity of 4,000 kilowatts.

DETAILS OF A ROTATING-FIELD ALTERNATOR.

In Fig. 48 is shown a 105-kilowatt revolving-field alternator, having a direct-connected exciter, and arranged for direct-connection to an engine. The revolving-

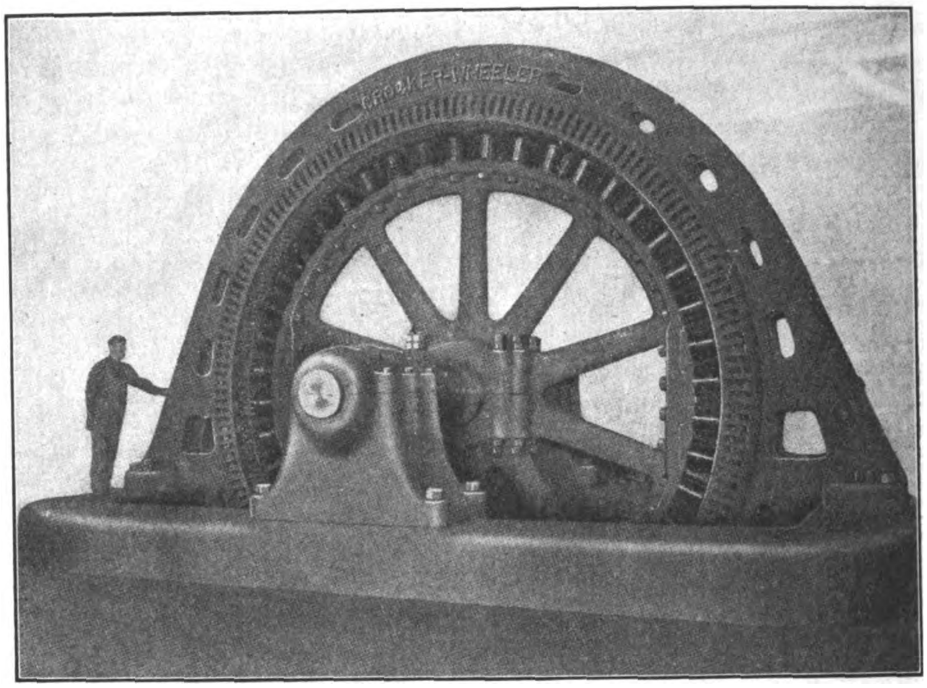

FIG. 47.—4,000-KILOWATT, 6,600-VOLT REVOLVING-FIELD ALTERNATOR.

field structure is shown in Fig. 49, while a more detailed view of the field coil and laminated pole-piece is disclosed in Fig. 50.

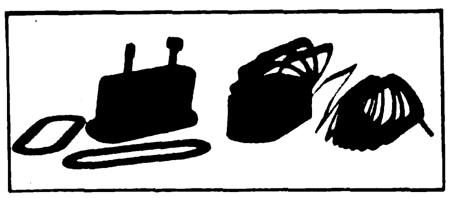

FIG. 50.—LAMINATED POLE-PIECE AND EDGE-WOUND FIELD COIL.

The alternator frame, illustrated in Fig. 51, shows the armature windings on the inner side. In the rear are the coils and frame of the magnetic field of the

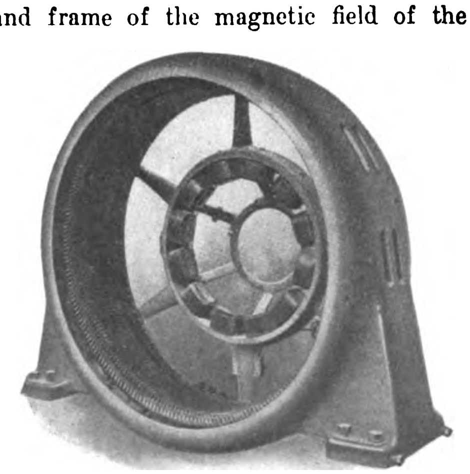

FIG. 51.—ALTERNATOR FRAME AND EXCITER FIELD.

exciter, the armature of which is illustrated in Fig. 52. This is mounted on the shaft close to the revolving field and generates a direct current to supply the field coils.

Fig. 53 shows the method of winding the separate armature coils, which are shown assembled in place in Fig. 51.

A detailed view of the arrangement of

FIG. 52.—EXCITER ARMATURE.

the armature coils of a 500-kilowatt alternator of the revolving-field type is shown in Fig. 54.

EXCITATION.

Most generators of this type are separately excited. In some cases the exciter

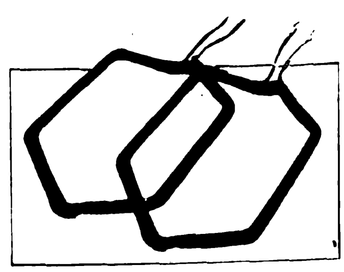

FIG. 53.—ARMATURE COILS.

armature is mounted on the same shaft with the field coils, as already shown in Fig. 48. With large generators, the exciters are usually belted either to the alternator or directly to the prime mover, or may be driven by a separate engine or motor. The electromotive force of the exciter is usually about 125 volts.

COMPOSITE EXCITATION OF REVOLVING-FIELD ALTERNATOR.

In sizes below 100 kilowatts capacity it is customary to build machines with composite field windings, as illustrated in Fig. 55. G represents the alternator and D the direct-current exciter. Y is the shunt-wound field coil of the exciter and X the series coil. The shunt winding contains the rheostat, r, while another

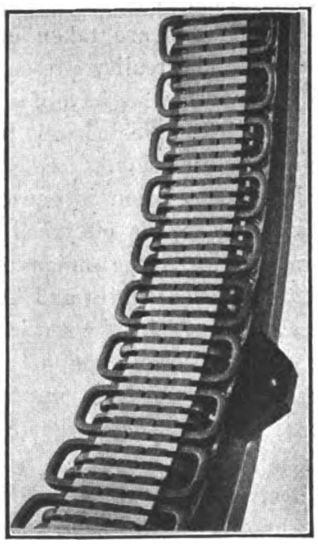

FIG. 54.—STATOR FRAME, SHOWING ARMATURE COILS IN POSITION.

rheostat, R, is connected in series with the exciter circuit. The circuit terminates in the collecting rings, L, which conduct the current to the revolving field coils. The two rheostats allow a wide range of variation of the exciting current. Additionally the commutator, C, feeds the field coils from the transformer, T, whose primary, P, is in series with the line, while the secondary, S, is connected to the commutator, C, which rectifies the current delivered to the field coils.

VENTILATION.

The hysteresis losses in the iron cores of the armature and fields appear as heat, as do also the I^2R losses in the conducting coils and the eddy current losses. It is, therefore, very essential that proper precautions be taken for cooling both the armature and the field. An excellent method of accomplishing this is illustrated in Fig. 56. The air passes up through the ventilating ducts of the field cases and then through those of the armature as shown by the arrows.

VOLTAGE CONTROL.

Voltage control of large alternators is usually attained by hand regulation, and an attendant is stationed at the switchboard for this purpose. For medium-sized machines, however, automatic regulation is being introduced to some extent as, for example, by the Tirrill regulator, which is essentially an automatic field rheostat.

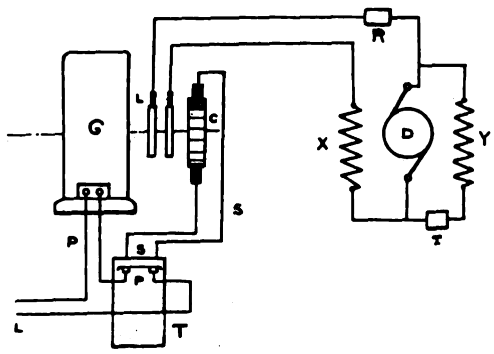

FIG. 55.—COMPOSITELY-EXCITED ALTERNATOR.

It operates by periodically short-circuiting a fixed resistance, instead of varying the amount of resistance in the circuit. The effect is practically the same as cutting out some of the resistance in circuit. With a normal resistance of ten ohms which is short-circuited for one-half the

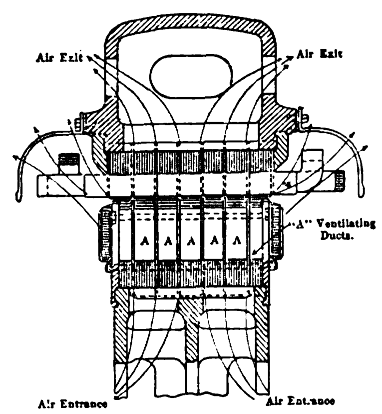

FIG. 56.—CROSS-SECTION THROUGH FIELD AND ARMATURE, SHOWING VENTILATING DUCTS.

time the result is evidently the same as if there was a resistance of only five ohms in the circuit.

New York Independent Telephone.

Justice McLean, in the New York Supreme Court, Friday, December 11, reserved decision on the application of the New York Independent Telephone Company, for a writ of mandamus to compel the Commissioner of Water, Gas and Electricity of New York city to permit it to run an electric wire through the pipe of the Empire City Subway Company, along the south side of Wall Street, from William to Hanover Streets. The corporation counsel opposed the application, and said that, while the application was only for a writ for that one space, it was, in reality, an attempt to get the use of all the city streets and subways.

Non-Magnetic Yacht for Ocean Surveys.

The Carnegie Institute, Washington, D. C., has awarded a contract to the Tebo Yacht and Basin Company, of Brooklyn, N. Y., for what will be in many respects a unique vessel. The Department of Terrestrial Magnetism of the Institute has authorized Wallace Downey, the builder of the yacht Meteor, for the German emperor, to construct a yacht to be used in making surveys. It is understood that, with one possible exception, there will not be a scrap of steel or iron in the craft, although it will, of course, be provided with an engine, machinery, and all other equipment of a modern vessel.

The yacht is to be called the Carnegie, and will be used in making ocean surveys. It is planned to eliminate errors which have crept into ocean surveys, due to magnetic variations, caused by the influence of steel on board ships. The vessel will be 155 feet long, thirty-three feet beam, twelve feet draft, and will be barkentine rigged and cost approximately $125,000. It will be primarily a sailing vessel, with an auxiliary gas engine. The propelling engines, machinery and other parts of metal on the craft will be of manganese bronze and gun metal. The contract calls for the delivery of the vessel to the Carnegie Institute by July 1, 1909, and it is announced that its first voyage will be to the North, visiting Hudson Bay and Greenland.

Electric Traction at Odessa.

The *Elektrotechniker* announces that the municipality of Odessa has decided to construct a system of tramways, and has granted a concession to a Belgian company which holds similar rights over the present horse lines. The system in question, says the London *Electrician,* will have a mileage of ninety-five, half of which will be single-track. The gauge will be one metre, and Phœnix rails, weighing ninety pounds per yard, will be used in the town and Vignoles rails, weighing seventy-six pounds per yard, in the suburbs. The trolley system will be adopted throughout. The generating station will contain four generator groups, each having a capacity of 1,000 kilowatts. Alternating current will be distributed at the generator pressure of 6,000 volts to six substations, where it will be transformed to continuous current at 550 volts. The rolling stock will be made up of 250 motor cars, as well as trailers. It is estimated that the total expenditure will exceed £1,250,000.

Co-operative Credit Protection.

An address on "Co-operative Credit Protection" was delivered before the Chicago Credit Men's Association by Frederic P. Vose, secretary of the Electrical Trades Association of Chicago, last month. Mr. Vose said in part:

Co-operation in business is an economic ideal; in social science it is applied to voluntary unions of persons; in matters of joint protection, purchase, distribution, consumption and the like on an equitable basis for their mutual benefit. It is the concert of many for the compassing of advantages impossible to be reached by one. It is fraternal.

We have all learned that commerce does not necessarily mean relentless competition and eternal strife; rather it is intercourse and exchange not only of wares and merchandise but of thoughts, ideas and practical information, and we have in this co-operative association work a combination or mutualization which makes for business morality, stability and prosperity. It is thoroughly opposed to petty trade jealousies, levels the selfish barriers between competitors and promotes the spirit of conciliation and unity of interest between those engaged in the same line, and from its inception has taught that co-operation and not competition makes for the more abundant and satisfactory life in and out of trade.

"Co-operative credit protection" has become the motto of organizations formed in the electrical trade as well as those among manufacturing and jobbing plumbers, heavy and light hardware dealers, jewelers, woolen manufacturers, paint manufacturers, stationers, brewers, butchers, bakers and candlestick makers, and a thoustand and one more.

Confining ourselves now to the consideration of how these organizations work, it is sufficient to say that in the main those engaged in a given line of trade become members of a corporation, organized not for pecuniary profit but in order to secure a more cordial feeling between members for the protection of their mutual interests and for the collection and distribution of valuable trade information and to protect them against making unsatisfactory credits. All members are supplied with certain uniform blanks or forms and when a customer of a given member does not respond to the usual demands for settlement of a past-due account, that member, in lieu of sending the claim at once to an attorney for collection, forwards to the delinquent Form No. 1, which calls upon him to pay the amount of the claim within three, five or ten days from date, and states that if it is not done the matter will be handed to the Co-operative Credit Association for attention, but ending with a statement that prompt remittance will render this action unnecessary.

If, after the lapse of the time specified, no satisfactory results have been obtained, since the circular letter No. 1 was mailed, the member sends to the association office Form No. 2, advising the secretary of the name and address of the tardy customer and the amount owing, whereupon the secretary sends Form No. 3, which is the last form, or communication, which the delinquent receives, in which the customer is advised that his name has been reported to the association as delinquent in his payments to a given member named, and also the amount of the indebtedness. He is urged to settle the amount within ten days. This form letter ends substantially as follows: "Should there be any question whatsoever as to the justice of the claim, or as to its being past due, the secretary will be glad if the customer will at once send a full statement of the facts so that the matter may be carefully investigated, as it is not the intention to do an injustice to anyone." Right here, you perceive, that the alleged delinquent is thus granted his day in court. If he is honest and business-like he will at once respond by making payment in whole or in part, or offer a satisfactory reason for deferring somewhat. All answers are carefully considered by the association and no honest debtor has cause to complain, as his rights are safeguarded equally with those of the members themselves. But if this form does not effect a satisfactory settlement of the account within the stated ten days, then, upon written request from the member, and with his permission, the indebtedness is reported to all of the members of the organization in a confidential communication, which simply gives the name of the delinquent customer, his address and the amount of the indebtedness. This information along with about a hundred other names is sent out by the organization twice each week. The form states that the information is strictly confidential and for the exclusive use of the member who is directly interested in receiving same for his credit protection and that it is not intended to impute dishonesty or financial irresponsibility to the customers named therein.

As soon as the account is settled the name is immediately withdrawn and the members are at liberty to sell the party on such terms and extend such credit as they may deem warranted.

Shortly after the first of each month, printed booklets containing about 5,000 names that have been reported to the association for unsettled indebtedness are distributed among the members and all the information that goes forth on the supplemental forms throughout the previous month appears in the book. Those names reported delinquent are added to the book and the names of those who have settled their accounts are taken out, so that the monthly in reality presents the names of customers who have failed to liquidate admitted indebtedness to the members of the association.

The Chicago association is one of the five organizations in the electrical trade carrying on identically the same work, so that the entire United States and Canada are practically covered by the service, and about 450 of the leading manufacturers and jobbers throughout the country are thus co-operating in the exchange of credit facts.

From the statistics at hand the Chicago association has collected for its members during the twelve years that it has been operating, over $2,000,000 of delinquent accounts. The amount settled during the past year exceeds $286,000. The average amount, therefore, collected for the 200 members of the association during the past fiscal year was $1,430. If these accounts had been turned over to an attorney and collected on the usual ten per cent basis the commission would have figured $143; as against this the members have simply paid annual dues to the extent of $30, so this is a net saving to each of them of $113.

The ratio of accounts collected through the association to those reported this year has been seventy-five per cent; last year it was seventy-four per cent, and the year before seventy-seven per cent; the year before that seventy-six per cent. This does not take into consideration the number of accounts that are settled by the use of Form No. 1 simply, of which the association has no record, as this form is sent direct by the member to the customer, but from reports recently received at this office it would appear that Form No. 1 alone effects settlements anywhere from sixty-five times to ninety times out of a hundred, and this, too, without any aid from any collection agency or commissions or fees paid to attorneys.

FINANCIAL REPORTS OF ELECTRICAL COMPANIES.

SYRACUSE RAPID TRANSIT.

The Syracuse Rapid Transit Railway Company's report, as filed at Albany, for the quarter ended September 30, 1908, shows as follows: Gross, $335,648; expenses, $228,023; net, $107,625; taxes, $15,356; operating income, $92,269; other income, $1,095; gross income, $93,364; charges, $90,282; net income, $3,082, a decrease of $34,039, as compared with the corresponding quarter of 1907. Cash on hand September 30, 1908, $41,354; profit and loss surplus, $478,013

CHICAGO & MILWAUKEE ELECTRIC.

The receivers of the Chicago & Milwaukee Electric Railroad report for the month of October and from January 28 to October 31, 1908, as follows: October—Gross, $49,325; expenses, $41,803; net, $7,522. January 28 to October 31—Gross, $468,451; expenses, $330,507; net, $137,944.

Net earnings for October were the smallest of any the current fiscal year, while August, with net of $35,572, was the best.

SCHENECTADY RAILWAY.

Schenectady Railway Company's report, as filed at Albany, for the year ended June 30, 1908, is as follows: Gross, $979,682; expenses, $723,305; net, $256,377; other income, $12,678; total income, $269,055; charges, $125,889; surplus, $143,166, which compares with $196,820 for the preceding year.

CHICAGO TELEPHONE.

The Chicago Telephone Company's earnings for the ten months ended October 31, 1908, are as follows: January 1 to October 31—Gross earnings, $7,211,039; operating expenses, $3,276,878; net, $3,934,161; maintenance and reconstruction, $2,027,533; balance, $1,906,628; dividends and reserves, $1,817,205; surplus, $89,423, as compared with $159,487 for the same period of 1907; average number of stations, 215,562.

President Sunny says: "November marked the turn, however, as is shown by the following: There were installed 4,708 new telephones, or an increase of 488; there were removed 2,397 telephones, or a decrease of 719, making a net gain of 2,311.

"Because of the general business depression, traffic during the year up to November 1 was somewhat less than in 1907, notwithstanding a large increase in the number of stations. Since November 1 there has been a marked and satisfactory increase in the number of telephone connections, a sure indication of a return to normal conditions.

"Telephones installed in the eleven months to December 1 were 59,817, an increase of 2,400; telephones removed were 33,650, an increase of 6,144; a net gain of 26,167, a decrease of 3,744."

Skyscrapers Discussed at Stevens Institute.

On the afternoon of December 3 the students of Stevens Institute of Technology, Hoboken, N. J., were afforded the pleasure of hearing a lecture on the construction of "Skyscrapers," given under the auspices of the Engineering Society.

The speaker was Charles G. Armstrong, the architect of the Singer Building in New York city, and his treatment of the subject was limited more particularly to a consideration of that structure. Starting with a definition for "skyscraper" and the necessity for its erection, Mr. Armstrong immediately digressed to the subject of elevators, clearly pointing out the fact that the modern skyscraper was almost totally dependent for its usefulness upon the modern elevator.

By means of lantern slides the speaker drew a comparison as to size between various noted edifices of the world, and after a brief sketch of the general proportions of the Singer Building began an exposition of how it grew. Especially interesting was the description of that hazardous work necessary in all skyscraper construction on Manhattan Island—the sinking of caissons to bed-rock in order to obtain proper foundations. Special attention was paid to the manner of anchoring the massive tower. In this connection Mr. Armstrong stated that the feet of the tower columns were secured to the foundations in the sub-cellar by stout steel tie rods running down forty feet in the concrete, and that the enormous lifting force of 250,000 pounds per square inch would be necessary to budge a column. Some interesting photographs taken during construction made apparent the danger of the housesmith's occupation.

Turning to a consideration of the structure as a completed unit, the speaker described its various conveniences and luxuries: Costly bronze grille work, expensive marble, elaborate office furnishings in the way of plumbing, ventilation, automatic heat control, vacuum cleaning apparatus, bell and telephone service, etc. A matter of special interest presented, typical of twentieth-century progress, is the elaborate clock system, one master clock in the main hall having control over hundreds of clocks elsewhere in the building.

After a short description of the various safety devices and signal apparatus, shop facilities for repair work, etc., Mr. Armstrong took up the consideration of power. He stated that the Singer Building uses as much power as a moderately sized city —approximately 2,000 horsepower. Boilers, engines and electrical apparatus are of the highest type, securing economy, convenience, and safety adequate to wide possibilities of accident and extremes of load. Mr. Armstrong also described the external lighting system of the tower, used for advertising purposes.

In closing his lecture Mr. Armstrong made an appeal to technical men to take up as a vocation the operation of great power plants and buildings, with the view of improving upon the wasteful methods of running them today. He then presented to the Institute a handsome litho-engraved picture of the Singer Building, eight feet high.

Independent Telephone Men Make a Bid for Long-Distance Service.

An offer has been made to the Chicago City Council Committee on Gas, Oil and Electric Light, by C. H. Moulton, of Indianapolis, president of the International Independent Telephone Association, and H. D. Critchfield, of Milwaukee, general counsel of the association, and president of the Wisconsin Independent Telephone Association, to take over the telephone franchises and properties of the Illinois Tunnel Company. As a companion offer, the Independent companies announced that they would enter into a contract with the tunnel company to connect with its telephone lines inside the city, providing it would agree to establish, within two years, a system of 20,000 telephones in Chicago and extend the system so as to get its share of the Chicago local business.

The Council committee has taken no action on either of these proposals, but in this connection an amendment to the ordinance which would give the tunnel company two years more to meet the requirements of its ordinance was discussed. This amendment would allow the two years' extension on condition that the tunnel company contract with the operators of long-distance lines other than the Bell system for an entrance into Chicago.

MERGENTHALER LINOTYPE ELECTRIC-MOTOR DRIVE.

BY S. H. SHARPSTEIN.

Several years ago Perry Walton, who was then purchasing agent for the *New York Journal,* found that the monthly bills for driving a small number of Mergenthaler linotype machines in the Morgen *Journal* office by electric motors were increasing out of proportion to the amount of work done.

As the *Journal* was buying electricity from the New York Edison Company, Mr. Walton requested that it make an investigation. It reported that the meter was in proper condition. Later the manufacturers of the motors were asked to try to locate the cause for the increased current consumption, and they sent a man who seemingly rectified the trouble.

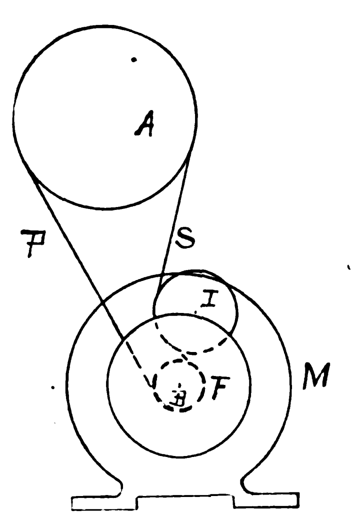
After a little investigation, Mr. Walton found that the motors, which were located in, and geared to, the linotypes, had bearings close to the driving pinions that were supposed to be lubricated by oil feeding from small cups. It was then, as now, customary to lubricate motors by means of ring bearings that would operate at least a week without attention, but special bearings on the motors mentioned above required almost constant attention, or they would run dry and produce excessive friction.

The classes of motors that have been installed in many cases to operate Mergenthaler machines are inferior and have almost driven the managers of newspapers back to the use of shafting drive.

One of the best authorities on print-shop practice, a man of long experience with motor drive, advised one of the New York dailies to adopt group **drive in** preference to individual motors. Group drive was installed with one exception. A Mergenthaler machine that was located on another floor was driven with a late type of electric-motor drive, and the armature of the equipment burned out during the first month that it was in operation.

Individual motor drive has some good features which group or shafting drive has not. One argument in favor of group drive is that the power of the larger motor installed to drive the four or more linotypes has sufficient capacity to maintain the speed when the type-casting device, at times, requires excessive power. This extra demand for power can be met when the individual motor is used by placing a flywheel F on the motor shaft, as shown in the illustration. With group drive, even though the motor be large, the belt running from the shafting to the Mergenthaler may slip, but with a good individual motor rig, under normal conditions it cannot.

Referring to the illustration, assume that A is a driven pulley on a linotype, M a motor installed to drive it by means of a belt. If the pulleys A and B are wide enough to take a good pliable single leather belt of sufficient width to drive the linotype under all normal conditions, B having a flywheel rim F that will produce a momentum to pull the linotype at any time when it requires power above the capacity of the motor, and an idler pulley I be provided to operate on the slack side S of the belt with a spring to compel it to follow up the belt when it happens to stretch, no surer drive can be had when the apparatus is properly designed and constructed.



LINOTYPE MOTOR DRIVE.

With group drive, the shafting is usually placed on the floor near the machine, necessitating a short belt between the pulley on the linotype and the pulley on the shafting. Almost any belt will change in length with the changes in the weather, making it next to impossible to get the best belt-driving conditions where it is so short, without a good idler pulley.

If the idler pulley is of the right diameter to keep its revolutions per minute low, its bearing will not require lubrication when properly made and installed. A slight spring pull that will follow up the belt is of more importance than excessive idler-pulley tension with no spring. A motor of the right design and speed will allow of starting with a switch located in a convenient place, without the use of a starting box.

Where the men operating the linotypes get their pay by the piecework system, they often want the machine to run above normal speed. All individual motors installed to drive such machines should be capable of having sufficient speed variation by inserting resistance in the field winding to give an increase of about fifteen per cent above the normal speed of the motor. It is poor practice to try to get this speed variation by placing resistance in circuit with the armature, which is sometimes done. If there is not some way of easily changing the speed of an equipment, when a motor is used, it is rather difficult to get the proper revolutions, as no two motors of the same capacity and manufacture are apt to have like speeds on the same voltage, and again, the pulleys may be arranged for a certain line voltage which will vary a small percentage.

Good practice demands that a motor, which is to be used to drive Mergenthaler linotype machines, either by being belted or geared direct, or by means of group drive and shafting, should be capable of having its field strength varied sufficiently to allow a speed variation of about fifteen per cent without excessive sparking at the brushes and that it should be supplied with a small field rheostat to be placed, in case of individual drive, where it is easily accessible to the operator, and with group drive near the motor. In the latter case a combination starting box and field regulator would be best.

The Mergenthaler linotype machine is a well-made and expensive piece of apparatus, but for some reason there has seemingly been undue pressure to keep down the price of electric motors used for individual drive. The result is in many cases a large amount of money invested from which the proper returns are not obtained, because cheap electric drive keeps down the production. To be in line with the Mergenthaler and the importance of the work, the electric drive should be the best that motor manufacturers can turn out.

When it is desired to place these machines in scattered positions and not in straight lines, side by side, the use of individual motors is almost imperative. After the use of direct drive is decided upon, the question comes up of supporting the motors from the linotype frame or placing them on a small base on the floor. If the motors are supported from the driven machine, the equipment can the more easily be moved from one place to another, it is easier to clean about the machines, and the motors are not so liable to get dusty. On the other hand, if the motors are placed on neat pedestals, they are easy to inspect and repair and are not so liable to be in the way when oiling or repairing the linotype. In the above cases it was assumed that belt drive would be used. The belt is often objected to on the point of appearance, but it is a very flexible transmitter for such purposes and allows the motor to be made up of standard parts, which is of the utmost importance to the printer. When the electrician in charge of the motors wishes to make changes or repairs to them, he can do so without interfering with the linotype if belt transmission is used. It is a good machinist's job to get a motor in position so as to make gears mesh properly when once removed.

The speeds of motors for individual drive should be sufficiently low to allow being belted direct to the linotype. Intermediate shafts with their extra belts are not good practice and should never be adopted unless for special reasons. Sometimes direct current cannot be obtained where direct drive is desired. Engineering difficulties might arise in case it was desired to use alternating current, making it advisable to have a secondary shaft on the motor. Especially when individual motors are used, they should be enclosed to keep type metal from getting into them. It is desirable to have the binding posts protected by an iron case, provided with a cover to allow connecting up and testing, and a hole tapped into one side to take a pipe into which the wires are to be pulled.

When group drive is used it is essential to get the linotypes divided up, so that they can be operated to advantage. If, during a portion of the day, only four men are employed at the machines, there should be a one-horsepower motor belted to a shaft to drive the four machines.

It is not economical to have a five-horsepower motor driving a shaft to which twenty linotypes are belted, of which only four are in use. An installation of sixteen machines of this kind is arranged in four groups of four machines each, the motors being placed next to the wall at the ends of the shafting. With this arrangement the equipments look well, the motors are out of the way, the motor starters are placed conveniently on the wall, and the whole electrical equipment is where it is not liable to be tampered with or damaged by careless or mischievous persons.

A one-horsepower motor is sufficiently large for four machines, if they are placed the regular distance apart and the shafting is properly installed with sufficient hangers. A motor that will do one horsepower of work at the pulley for ten hours without more than the usual rise in temperature, can be made to drive more than four machines, but it is wise to have the usual load of the motor below the normal rating, allowing a surplus for times when a bearing may be dry or a belt tight enough to cause excessive friction.

Ordinary shafting practice will not answer for linotype purposes. It usually requires about one-fourth horsepower to drive one of these machines, until the casting apparatus seems to stick, when much more power is required. The main shaft of the linotype, on which is placed the driven pulley, has a very low speed. The result is a low belt travel, demanding a heavy belt for transmitting only one-fourth horsepower. If a contractor installs a line of shafting to transmit power to drive four of these machines at one-fourth horsepower each, when the linotype machinist puts on his belts the shafting is almost pulled from the floor and trouble begins at once. Unless a very heavy shaft is used, in proportion to the work to be done, the floor hangers should be first-class, with ring-oiling devices.

When the linotypes stand side by side, with ordinary distances between them, the belt pull, which is upward, lifts the line shaft up against the top of the box in the hanger. If the ordinary oiling devices for hangers are used, the shafting, being out of reach of them, gets no lubrication, and soon commences to cut out the bearing. The ring oiler running around on the shaft as it turns, carries the oil from the reservoir in the box to the top of the shafting, and with a properly made bearing lubricates the shaft regardless of whether it touches top or bottom of the bearing. Good practice demands a hanger close to the motor pulley and also near each pulley used for linotype drive.

Many electricians who wire electric motors do not seem to understand how to place an idler pulley to keep the slack out of a short belt. At times the idler pulley is put on the pulling side of the belt and set up hard enough to make the belt operate the load, and then the equipment is condemned as worthless.

If the motor-driving pulley is small compared to the driven pulley, the belt should be slack enough to let the idler pulley, which should be on the motor, force the belt to wrap about one-half of the driving pulley, then, if the belt is pliable, there is not much spring tension necessary to keep the troublesome slack out of the belt.

Possibly the best argument in favor of group or shafting drive is the lower cost of maintenance and higher motor efficiency of one large motor as compared to a number of small ones.

If the individual motors are made of standard parts of first-class motors, the maintenance and efficiency will be of small importance compared to the flexibility and reliability of individual drive. All motors will require renewal of brushes and repairs after a time. If a five-horsepower motor should stop, for want of oil or a brush, and put twenty linotypes out of commission, when there was a rush for composition, the expense of the shutdown might cover the small cost of maintenance on twenty good individual motors for many years.

Western Union Dividend.

The directors of the Western Union Telegraph Company have restored one-quarter of one per cent to the dividend rate, which was reduced last summer, by declaring a quarterly dividend of three-quarters of one per cent, payable January 15 to stockholders of record of December 19. This places the stock on a three per cent annual basis, compared with the old rate of five per cent, which prevailed previous to last July 15.

The report for the quarter ended December 31, with figures partly estimated, shows net revenues of $2,000,000, an increase of $1,196,057 over the same quarter in 1907. The surplus, after the payment of dividends and bonds interest, was $820,115, which, compared with last year's deficit for the same quarter, shows an increase of $1,666,235. By combining, the last two quarters of the year show net earnings of $3,864,955, an increase for the six months of $3,372,505.

Commenting on the increase of the dividend for the current quarter, President Clowry said: .

"Notwithstanding the setback caused by last year's strike and the long depression which followed, we feel encouraged with reference to our business. We paid one-half of one per cent dividend for the quarters ended June 30 and September 30, or at the rate of two per cent per annum. For the present quarter ending December 31 our estimated net earnings over and above all fixed charges are one-and-one-half per cent, or at the rate of six per cent per annum, and it was deemed best to increase the dividend three per cent per annum."

Electrification of Railroad Terminals Discussed by Steam-Railroad Men.

On the evening of December 11, the Electrical Section of the Western Society of Engineers held a meeting in Chicago for the further discussion of the paper that was read before the main body of the society on December 2, by H. H. Evans, entitled "Developments in Electrification of Railway Terminals." An abstract of this paper appeared in these columns last week.

The discussion was opened by Chairman D. W. Roper, who traced the history of urban transportation and compared the transit means of some thirty years ago with conditions of today. Throughout the days of horse and cable cars, there was a long gap between the length of haul of street cars and of steam suburban roads. The introduction of electric cars caused a decided lengthening of haul and reduced the suburban traffic of the steam roads. The elevated railroads have increased this tendency and brought still greater speed and further inroads on steam suburban service. These factors have brought electrification of this service to the front. Electrical operation permits higher speed than steam. Still higher speeds will be required in future to accommodate the suburban resident who wishes to spend not more than thirty or forty minutes in going to and from his home.

W. B. Storey, Jr., chief engineer of the Santa Fe Railroad, contended that the statement, that electrification of the Illinois Central or other roads is inevitable, is not justified. He does not believe that electrification of terminals in Chicago is feasible or necessary. The smoke nuisance is the only possible excuse for such an undertaking. This is not caused, however, by railroad smoke, but by the smoke problem of the city as a whole. Railroad smoke is only a very small part of the total produced. He does not believe that electrification in general doubles the capacity; it may be that the new terminal of the New York Central may have twice the capacity of the old one on account of extraordinary conditions, special new features and rearrangements aside from electrification, having largely helped to increase this capacity. Mr. Storey contends that the nuisance due to steam operation is insignificant, especially in Chicago. The extra cleaning of passenger coaches is a trifling feature in his opinion. Deterioration of steel work in viaducts is not marked, if these are properly protected. He admits an increase of capacity, due to some dead mileage being eliminated. The railroads wish to have detailed figures given showing the advantages of electrification. The electrification of at least one of the California railroads that were cited was for the object of selling current, as the company bought the road only to use up some of the surplus electrical energy from its large plant; he thinks it was a great mistake. Mr. Evans' statement as to maintenance of electric locomotives being not over three cents per mile, he does not believe to be justified, as the experience with electric locomotives is too short, nor does he believe that electrical equipment is at all standardized as yet. Advocates of electrification should separate their statements about multiple-unit and electric-locomotive operation and give figures for each. He admits that the electrical operation of new heavy suburban lines is warranted, but not the general electrification of terminals. The building of warehouses over tracks is feasible with steam roads also, and, in fact, has been done. He contends that the scheme as to fast and frequent freight service is entirely impracticable, as railroads cannot do what they wish in the operation of freight traffic, but must meet the wishes and conditions imposed by the shipping public. The electrification of the terminals of the New York Central and Pennsylvania railroads in New York city is justified, as it increases their capacity and is necessary in tunnel work. Such conditions are not present in Chicago. It has plenty of room to expand. When economic conditions require it and when definite figures of possible savings are presented, the railroads will be glad to adopt electricity. Where electrification has been adopted in the projects that Mr. Evans cited, it was due to tunnels or special conditions or to governmental experiments, but not due to private corporations voluntarily putting millions into such projects. As to the Illinois Central, he does not believe that the $4,000,000 estimated will be at all sufficient, nor even twice that amount.

W. E. Symons, president of the Pioneer Cast Steel Truck Company, asserted that dust in railroad travel is not caused by steam locomotives, since less than three per cent is due to cinders and soot, most of it being due to air currents caused by the suction of trains. In Chicago over eighty-three per cent of the smoke of the city is caused by other than locomotive chimneys. Damage to property due to railroad nuisances is nil; on the contrary, railroads have enhanced values tremendously. Steam transit is by no means unattractive; the steam locomotive is as fine a piece of mechanism as there is. No reduction of expenses due to wear and tear of rolling stock may be expected from electrification, as this is due principally to switching, and would not be minimized appreciably; it is even now always kept down to a minimum. The standardization of steam-locomotive equipments has not been carried out to a high degree in general, as great variation exists in type of engine and sizes of cylinders and other parts, and since it is almost impossible with diversified management and the conflicting ideas of various division heads as to type of motive power. To show the possibilities in this line, he cited the relatively high development of locomotive standardization on the Harriman lines, with 18,000 miles of railway, where the types have been reduced to five. With the electric locomotive in its present experimental stages, no standardization has been attained, in Mr. Symons' opinion. From the figures on maintenance charges of steam locomotives of three of the largest roads running out of Chicago which he had available, the speaker gave 4.6 cents as an average charge per mile instead of eight to eleven cents, as given by Mr. Evans. He also read extensively from the report of the superintendent of the Baltimore Division of the Baltimore & Ohio Railroad, showing that the maintenance cost of electric locomotives used in the Baltimore tunnel is from three to four times that of steam locomotives. Reduction of track repairs, he thinks, is not important, as eighty per cent of these repairs are caused by the elements, and not by service. In regard to the electrification projects around San Francisco, he spoke of the great traffic handled by the Southern Pacific Railroad during "Fleet Week" last May, while the electric "Key Route" made a dismal failure.

W. L. Abbott said that the steam engineers should wake up from their conservatism to a conception of newer engineering methods. No mention has ever been made by them about the scrapping of steam locomotives on the elevated roads. In Chicago and within 100 miles of it there is more electric than steam railroading. Mr. Abbott told a story about Cornelius Vanderbilt as showing how the railroads are becoming cognizant of the competition of electric interurbans. Considering that sixteen electric terminal projects have been carried out, he contended that the conservatism of the local railroad officials in refraining from the adoption of electrical methods does not reflect credit on this great city.

W. M. Camp, editor of the *Railway and Engineering Review,* thought that the public agitation of the subject is driving many, including the author of the paper under discussion, to hasty conclusions without proper consideration of actual conditions. Some of these conclusions, in fact, he regarded as far-fetched. For tunnel operation, especially at terminals, electrification is necessary, regardless of cost and possible saving. However, electrification of all terminals does not follow. The railroad smoke nuisance, he thinks, is a bugaboo. He spoke of the dense clouds of smoke over the Chicago Stock Yards and the Illinois Steel Works at South Chicago —no one ever speaks of these. Therefore the agitation about Illinois Central smoke was prejudicial. Experience has shown that we must always expect public clamor about various inconveniences of a large city. Let those who do not like the discomforts of a large city, go back to the country. The electric locomotive is still largely experimental. Conditions in Baltimore and New York are not typical, but special. The operation of the New York terminals has not been perfectly smooth. Many changes have been found necessary as the work progressed. He cited the bad wreck of a double-headed electric train on the New York Central terminal as being due, probably to faulty design of the locomotives. The Pennsylvania Railroad has experimented with various types, and adopted, he believes, a type quite different from the New York Central electric locomotive. He elaborated on the changes made in the New Haven locomotives, particularly the addition of idler wheels on the trucks. Aside from changes in wheel-base design, he cited from Mr. Murray's American Institute of Electrical Engineers' paper (referred to in another column) a long list of changes that had been made in both the mechanical and electrical features. All this shows conclusively that the electric locomotives are not standard, but experimental. So is the line equipment, as shown by the New Haven auxiliary trolley. The whole project, he regards, as still experimental. The railroads do not know yet which is better, the overhead single-phase or the third-rail system. If electrification of passenger terminals is to be brought about, why not that of the freight service, as it causes as much smoke and cinders as the others. For carrying this out an enormous expenditure would be requisite. The statement of maintenance of electric locomotives at three cents per mile is not according to facts. The repairs to armatures will probably be very great in heavy service. Track maintenance, particularly at curves, he thinks, will also probably be greater, due to concentration of weight low down on the trucks.

H. H. Evans closed the discussion by giving a great many data on maintenance costs per locomotive mile that verified his estimate of it as being below three cents per mile. He also gave authorities verifying his statement as to track maintenance. He called attention to the fact that the Baltimore & Ohio electric locomotives were the first electric locomotives used for heavy railroad service, and, in fact, that the service in the Baltimore tunnel was very severe. The entire installation there is twelve or thirteen years old and was in many ways below the standard of good practice of today. There is no doubt that railroads develop property values up to a certain point, when the attendant nuisances become excessive.

Ithaca Section, A. I. E. E.

At the meeting of the Ithaca Section, American Institute of Electrical Engineers, December 11, Prof. H. Wade Hibbard, head of the railway mechanical department of Sibley College, presented a paper on "The Handling of Men." This topic is one of unusual interest, but it is also one that receives comparatively little attention in technical schools.

Professor Hibbard outlined the features of executive work, and pointed out the essential elements of successful co-operation between employers and employes. He advocated courses of instruction in handling of men for undergraduates in technical schools, and instanced the Charlottenburg Technical High School of Berlin as an example. Professor Hibbard has had large experience and many opportunities for observation, and the results of all this were condensed into a trenchant and stimulating paper. The presentation of the paper was followed by a lively discussion.

In view of the fact that the local branch of the American Society of Mechanical Engineers was formed on December 10, a resolution was passed by the Ithaca section of the Institute, extending to the members of the new organization "the best wishes and assurances of hearty co-operation in their work and plans."

Pittsburg Section, American Institute of Electrical Engineers.

The regular December meeting of the Pittsburg Section of the American Institute of Electrical Engineers was held December 8 in the Carnegie Institute lecture hall, with W. Edgar Reed, chairman, presiding. The attendance was 110. The subject for the evening was "Some Experiences in the Use of Gas Engines for Electric Power Generation," an original paper by J. R. Bibbins.

In the discussion the following participated: Prof. W. Trinks, of the Carnegie Technical Schools; W. E. Moore, of the West Penn Railways Company; William Hoopes, of the Aluminum Company of America; C. D. Smith, of the United States Geological Survey; E. B. Tuttle and R. A. L. Snyder, of the Central District and Printing Telegraph Company; J. G. Schroeder, of the Union Switch and Signal Company; W. F. Flint and E. B. McClelland, of the Westinghouse Machine Company, and P. M. Lincoln, W. L. Waters and D. W. Burke, of the Westinghouse Electric and Manufacturing Company.

The subject of electric furnaces will be discussed at the next meeting, to be held on January 12, at which time an original paper will be presented by William Hoopes.

Franklin, the Telephone Man's Ideal.

In pointing out the value of promptly obtaining and turning over funds, as well as the saving of expenditure, in the operation of a telephone system, Roy Owens, engineer of the Citizens' Telephone Company, Columbus, Ohio, in a paper before the International Independent Telephone Association at Chicago, said:

"It is as true now as in the days of the first man who braved the lightning's current on an insulated line, that 'A quick sixpence is better than a slow shilling.'

"In such a meeting as this I ought not to pass an allusion to Benjamin Franklin without expressing a wish that our engineers might emulate his scientific care, our managers his thrift, our cashiers and contract agents his diplomacy, our spokesmen his strength of expression, our financiers his capacity for persuading funds out of the most unwilling of lenders, and all of us his zeal for knowledge."

Later in the telephone convention a member discussing the application of insurance to telephone properties, brought out the fact that the first insurance company in this country was organized by Benjamin Franklin, of Philadelphia.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

SIMPLE AND PRACTICAL METHOD OF ASCERTAINING THE CHARACTER OF A CURRENT.

In many instances it is of importance to know the character of the current feeding an installation, and in order to ascertain this it is sufficient to approach a magnet to an incandescent lamp fed by the current to be analyzed. If the current is direct the filament will bend each time the magnet is approached; if it is alternating, the filament will begin to vibrate in synchronism with the current and will appear to the eye as a filament of varying thickness. The phenomenon is very distinct and may be made to manifest itself by means of a small magnet that can be carried in the pocket.—*Translated and abstracted from L'Industrie Electrique (Paris), November 25.*

PROFESSOR MAJORANA'S EXPERIMENTS IN WIRELESS TELEPHONY.

The members of the Italian Electrotechnical Association were recently invited by Professor Majorana to witness his experiments in wireless telephony. Professor Majorana has constructed a generator furnishing continuous electrical waves of ten to twenty thousand periods a second. At the transmitting station he employs an arc in a hydrogen atmosphere with a magnetic blowout, the invention of Poulsen, in a Duddell circuit, and a hydraulic microphone invented by himself. A current of about 500 volts and ten to twelve amperes is used in the primary circuit. The operation of the hydraulic microphone, which is connected in the antennæ, between the secondary coil and the ground, is based on the difference in capillary contraction which the liquid column, consisting of a fine jet of acidulated water, undergoes under the influence of the voice. The liquid jet, which is thus continuously modified, presses on two metallic contacts and varies the resistance interposed between them. An ordinary microphone could not be used, as the high-tension currents would burn the carbon grains. As a wave detector the professor uses a thermopile of non-metallic (sulphurous) elements, as he found electrolytic and other wave detectors used in wireless telegraphy unsuitable for the purpose. Experimental stations have been established at the General Post and Telegraph Office in Rome and at Monte Mario, and a third station at Porto d'Anzio, a distance of fifty-four kilometres. The experiments were entirely successful, in spite of a heavy rain and frequent lightning discharges.—*Abstracted and translated from L'Elettricista (Rome), November 1.*

THE KINLOCHLEVEN WORKS OF THE BRITISH ALUMINUM COMPANY.

The British Aluminum Company has completed its 39,000-horsepower aluminum works at Kinlochleven, in the west of Scotland. The company was founded in 1895 to mine bauxite and purify it to aluminum at Larne, in Ireland. The electrodes were prepared at Greenock, Scotland; the reduction was carried on at Foyers, and the metal was worked up at Milton. At the present time the company is drawing its necessary raw material from its bauxite beds in the province of Var, in southeast France, the Irish deposits being kept in reserve. The works at Foyers is capable of developing 7,500 horsepower, and owing to its situation on the Caledonian Canal, communication with the alumina and electrode factories and rolling mills is both cheap and easy. These works have been in operation since the middle of 1896, but is not capable of meeting the rapidly increasing demand for the metal. The company therefore decided to develop the much more extensive waterpower scheme which it had had under its control for some years previously, and early in 1905 a commencement was made with the new works. The company also possesses works at Stangfjord, in Norway, and at Orsieres, in Switzerland, the total capacity of the various works being over 60,000 horsepower. The new development at Kinlochleven is equipped with water turbines of the high-pressure Pelton-wheel type. The whole plant consists of nine large wheels, with an output of 3,200 horsepower each, and two small turbines of 930 horsepower each. There are twenty main generators, each having an output of 1,000 kilowatts at 250 to 275 volts. They are coupled in pairs to the water turbines. All of the generators are of the direct-current, multipolar type, with slot-wound armatures. Each generator is capable of an overload output of 1,100 kilowatts for one hour. The Héroult process for manufacturing aluminum consumes a good deal of carbon, this substance being used in the furnaces and being burned away to carbon monoxide by the oxygen from the reduced alumina. The company has erected a factory for the manufacture of carbon at Kinlochleven, this factory being supplied both for power and lighting purposes by two pairs of aluminum conductors. A railway runs from the factory to the quay at the head of Loch Leven, transporting both outgoing and incoming produce.—*Abstracted from the Electrician (London), December 4.*

NEW APPARATUS FOR WAVE-FORMS.

M. Abraham, a prominent physicist of Paris, who has had considerable experience as an assistant to Professor Blondel in his work on the oscillograph, has devised an instrument which is much simpler and less expensive than the former types, and may be used for obtaining a direct projection of current waves upon a screen. The instrument has been constructed at the Carpentier establishment and consists of two distinct parts, one a special form of galvanometer containing a swinging mirror which is made to follow all the variations of the current; and a second apparatus which is interposed between the mirror and the screen and which serves to spread out the light coming from the mirror so as to give the form of the wave upon the screen. The construction of the galvanometer allows of the production of induced currents in a swinging frame in such a manner that the movement of the latter will follow exactly the variations of the current to be observed. In order to obtain this result an intermediate current is produced outside of the instrument, which is in quadrature with the current or electromotive force to be observed. In the case of an electromotive force a condenser is disposed in series with the galvanometer. For taking the current wave the current is passed through the primary coil of a small transformer whose secondary coil is closed upon the galvanometer. In practice two separate galvanometers are used, placed side by side so as to throw the two waves upon the screen. The intermediate current is thus sent into the fixed coil of the galvanometer, and this coil acts as the primary of a small transformer whose secondary consists of a short-circuited aluminum frame carrying a concave mirror. The second part of the apparatus, known as the synchronoscope, is used to spread out the beam of light which comes from the oscillating mirror. A revolving prism lies at the center of the synchronoscope and revolves the two beams coming from the two fixed galvanometers. The prism is totally reflecting and is caused to rotate rapidly in synchronism with the wave by means of a toothed wheel of soft iron, which is mounted so as to rotate between the poles of an electromagnet, the latter being connected to the source of current, this combination making a simple and effective synchronous motor. Should the prism be revolving and the mirror in oscillation at the same time, the combined action causes the wave-form to repeat on the screen, owing to the repeated reflections from the three sides of the prism; and the latter therefore gives three reflections of the wave per revolution. In order, however, to secure a better image upon the screen, the light which comes from the prism is not sent directly upon the screen, but is further reflected by a set of fixed plane mirrors which are disposed around the prism. These mirrors are placed so as to be about tangent to a parabola, at whose focus is placed the center of the prism. During the rotation of the prism the beam from each of its faces is reflected upon the four mirrors in succession, and at each reflection the curve is thrown in the same place upon the screen, so that for one revolution of the prism there are twelve successive projections of the wave on the screen. In practice the wave is thus traced as a continuous line of light and the electromotive force and current waves have their proper relative positions.—*Abstracted from the Electrical Review (London), December 4.*

THE APPLICATION OF LOW-PRESSURE STEAM TURBINES TO POWER GENERATION.

In this article J. R. Bibbins states that the entire potency of the low-pressure turbine lies in its ability to use a waste product or to so improve the general efficiency of a power system as to force a thorough consideration of its possibilities and limitations. In the engine the losses due to condensation and re-evaporation on cylinder walls during each consecutive cycle are large. In the turbine there is no cyclic change, and therefore no such losses, comparatively speaking, as a fairly constant temperature and pressure obtain at any given point in the expansion range. In the engine the mechanical friction of the enormous sizes of cylinders necessary to accommodate the lower expansion ranges constitutes an effective barrier. In the turbine the lower pressures may be used with comparative ease and without incurring excessive losses, mechanical or thermal. There are two general classes of service in which the low-pressure turbine finds effective field for application: Class A—Where the supply of steam is intermittent and widely varying in quantity, for example, in rolling mills, in driving steam hammers and in operating hoisting engines. All of these involve the regenerative principle, requiring a careful study of the time element in supply and demand, and generally resolving into a special problem for each individual installation. Class B—Intermittent supply without regeneration. This class embraces central power stations for lighting, traction or factory drive, and may be discussed as a general problem of power extension. A plant of non-condensing engines may be changed over to reduce its water rate from thirty or thirty-five pounds per kilowatt-hour to fifteen or eighteen pounds per kilowatt-hour. In other words, for the same expenditure of coal and water a net increase in power of from eighty to 100 per cent may be realized, depending upon the type of equipment. The resulting cost of power is reduced in the same proportion. From a thermodynamic standpoint the low-pressure turbine is the exact counterpart of the familiar complete expansion turbine and possesses the same characteristics as in the high-pressure turbine. The line of total consumption per hour, or water line, is practically straight, resulting in a constantly decreasing water-rate curve. The low-pressure turbine may be regarded as the third cylinder of a triple-expansion system and is equivalent to such a cylinder fitted with a fixed cutoff. A typical example of a low-pressure turbine application is found in the plant of the United States Coal and Coke Company at Gary, W. Va., operating the mining property, serving hoists, pumps, blowers, lights, etc. The low-pressure turbine has carried a little less than half the total load, which was 2,600 kilowatts, on less than twenty-six inches vacuum, and would have carried over 1,500 kilowatts on twenty-eight inches vacuum with better condensing conditions, giving a probable water rate for the engine-turbine plant of approximately 18.5 pounds per kilowatt-hour. Water-rate curves taken on this plant show that the two Corliss engines give an economy of 20.05 pounds per kilowatt-hour condensing and 28.8 pounds per kilowatt-hour non-condensing for a normal load of 1,000 kilowatts in each case. But in combination with the turbine a maximum water rate of 15.8 pounds per kilowatt-hour is secured.—*Abstracted from the Electric Journal (Pittsburg), December.*

THE PRODUCTION OF CAST-IRON IN THE ELECTRIC FURNACE AND IN THE BLAST FURNACE.

An investigation to ascertain whether the production of cast-iron in the electric furnace would in some cases be more economical than in the blast furnace was made by Engineer Remo Catania, and the results were communicated to the Italian Electrotechnical Association at its recent annual meeting. A definite comparison has so far been impossible, as the blast furnace must also be considered as an enormous generator of motive force, and as there are no data available relative to the gas developed by the electric furnace. The largest blast furnaces reach an output of 800 tons a day; electric furnaces producing eight kilograms of cast-iron per horsepower per day would consume 800,000 horsepower. In comparing the two processes one must take into account not only the amount of material introduced into the furnaces, but also that taken from them. In the absence of data concerning the amount of gas obtainable from electric furnaces the author bases his calculations on chemical equations, applying the same method to the electric furnace that has been applied to the blast furnace. The conclusion arrived at is, that in a country where coke costs forty lire per ton the manufacture of cast-iron in the electric furnace will be cheaper than in the blast furnace, if for a production of eight, ten and twelve kilograms per horsepower per day the cost of electric current per horsepower year is, respectively, sixty, eighty and 100 lire, and assuming a complete, rational and direct utilization of the gas in gas engines and not under steam boilers and in steam engines.—*Abstracted and translated from Elettricista (Rome), October 15.*

INDUSTRIAL SECTION

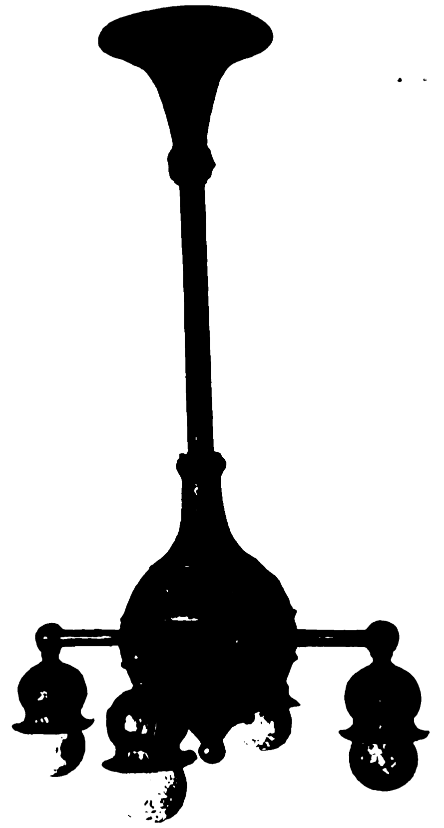
ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

New Westinghouse Nernst Chandeliers.

Besides establishing a great economy in the price of light of the best quality, the new Westinghouse Nernst lamp is responsible for the development of a line of chandeliers that give a greater volume of light for a small light source than it is possible to get with any other incandescent chandeliers ever made, says the manufacturer.

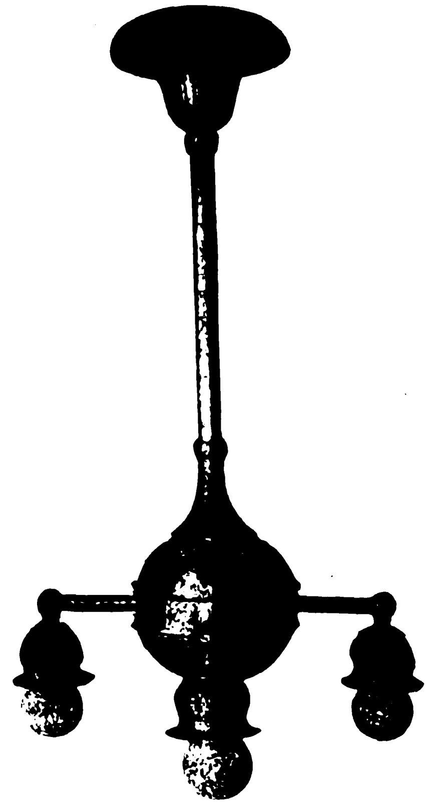
These chandeliers now being put on the market are made in highly artistic designs in the renaissance and art nouveau styles. They are made in solid castings or in a combination of castings and spinnings and finished as standard in statuary bronze and satin brass.

A novel feature about these chandeliers is the arrangement of the mechanism of



NEW FIXTURES FOR WESTINGHOUSE NERNST LAMPS.

the lamps in the central ornamental ball which conceals it completely and at the same time makes it easily accessible. This leaves nothing at the ends of the arms except the small screw-base burners, and these occupy less space than any other incandescent lamps of equal candlepower. The 132-watt burner, for instance, giving light equivalent to that of seven sixteen-candlepower carbon-filament lamps, occupies a space at the end of the arm of only three by four and one-half inches. This makes it possible to get a large volume of



NEW FIXTURES FOR WESTINGHOUSE NERNST LAMPS.

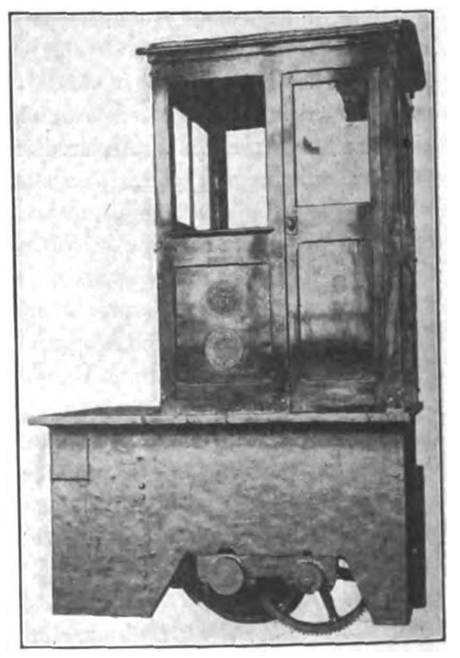
light without using a multiplicity of sources or infringing the law of proportioning by making the sources too large for the other parts of the chandelier.

Electrically-Driven Turntable.

For doing work of a purely laborious sort, requiring mere strength, the human animal is a very inefficient piece of apparatus when compared with such mechanical power devices as electric motors—inefficient, indeed, in point of size, weight and cost of operation. Nevertheless, it has long been almost universally the custom to operate turntables and transfer tables on steam railroads by man power. A striking example of the economy and convenience which results from the use of electric power for this service is shown by the installation of a motor on a turntable on one of the railroads in New York state.

This turntable was formerly operated by hand, requiring the time of a number of men at intervals, which averaged the continuous service of two men for twenty-four hours a day. The donkey was then equipped with a standard type F, high-torque Westinghouse induction motor, rated at twenty horsepower, and using sixty-cycle, two-phase current at 200 volts. This reduced the labor required to one man per day of twenty-four hours.

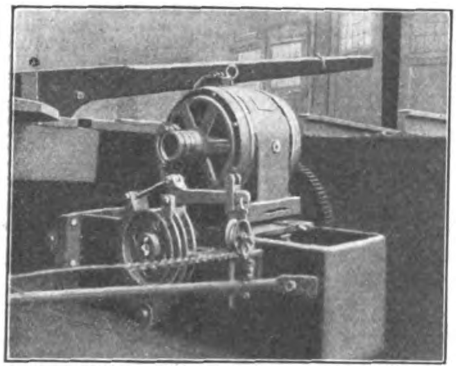
Inasmuch as the men were paid fifteen cents an hour in each case, this motor made a saving of $3.60 a day, or $1,314 per year of 365 days. As the cost of power for the motor has averaged but $8 a month, or a total of $96 a year, the net saving is $1,218 a year. The total cost of the electrical equipment, including the cost of installing the outfit, was approximately $1,500, which is but slightly greater than the actual saving in one year. As a result of this installation four other turntables have been supplied with elec-



CAB AND GEAR CASE OF MOTOR-DRIVEN TURNTABLE.

trical equipment by the same railroad, and plans are on foot for equipping several more similarly.

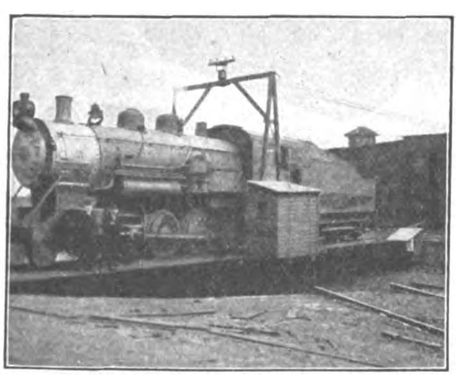
The economy is not the most important point among the advantages of the electrical equipment, although it makes a very good showing. The work of a turntable is intermittent and is usually rushing for a short time and then at a standstill, especially at terminals, where many locomotives often come in at the same time. The length of time required to turn a locomotive by hand depends largely upon the number of men available to do the turning, but even with the handles full (which condition requires from four to eight men), it is impossible to do the work as rapidly as with a motor. Hence the sav-



DRIVING GEAR ON MOTOR-OPERATED TURNTABLE.

ing in time at such periods is of great importance, as the congestion at the turntables is relieved and the movement of traffic is expedited.

The method of supplying power to the table has some interesting details. A bridge is used with overhead wires, which run to a standard Westinghouse overhead collecting switch. This switch is constructed with brushes and collector rings, so that contact is made at all times and in all positions of the turntable. This switch is so constructed that there is no



LOCOMOTIVE ON MOTOR-DRIVEN TURNTABLE.

strain on the line wires, as the cross-arm to which they run does not move with the tables, but is stationary while the table revolves.

In this installation the cab is mounted on the center of the turntable, so that the wires run directly from the bridge to the cab and to the motor. In many instances the cab is mounted at one end, but instead of being directly on the table, it is mounted on the donkey directly over the motor, to overcome the jolting which the cabman would get when the locomotives run on and off. The type of cab which the Westinghouse company has adopted as a standard for this work is shown in one of the accompanying illustrations.

In many cases, especially in a new installation, the feed wires are run underground in conduit and brought up through the king-pin in the center of the table. The same type of switch mentioned above is placed between the tracks, and the connections made from this point in the usual manner.

New Self-Starter for Induction Motors.

A distinctive feature of the new line of self-starters for alternating-current induction motors recently placed on the market by the J. L. Schureman Company, Chicago, is the use of solenoids to perform the various functions of the starter, thus corresponding closely to direct-current practice.

The accompanying half-tone illustration shows the simplest type of these starters, one designed for small motors, capable of being thrown directly across the line to start. It consists of a solenoid-operated switch for closing the motor circuit, together with a small relay, which makes possible reducing the amount of current in the control circuit to a minimum. All parts are mounted on a single slate panel with front connections, and legs for bolting to a vertical surface, making a neat, compact outfit, easy to install and mount.

The main switch is closed through a crank action, which requires very little power to operate, and permits the use of a solenoid of moderate size. No toggle joints are used. The circuits are made and broken on heavy carbon and copper "butt-end" contacts, which can be cheaply and easily replaced, and are very easy of adjustment

The operating solenoids are of a noiseless type and carry current continuously while the starter is in running position. This provides the no-voltage release feature, and in case of a failure of voltage from any cause the starter returns to the "off" position, disconnecting the motor from the line. The current consumed by the solenoids is only a fraction of an ampere.

The usual method of control is from remote push-buttons or by means of a pressure or vacuum regulator. Three small wires are run to the point of control. To start, momentary contact between wires 1 and 2 closes the circuit of the relay, which in turn actuates the main-line switch, connecting the motor to the line. Momentary contact between wires 1 and 3 short-circuits the relay coil, and the circuit to the main-switch coil

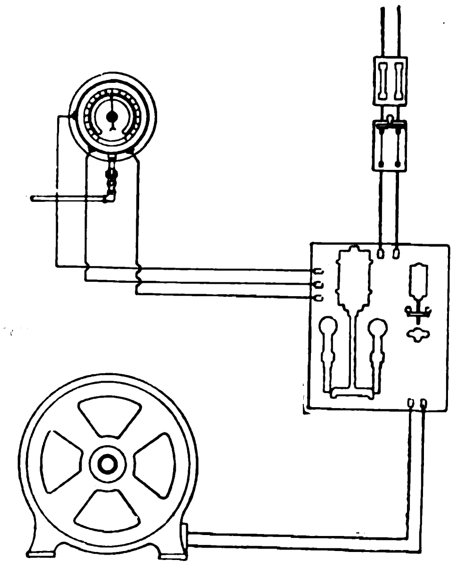


DIAGRAM OF CONNECTIONS FOR SCHUREMAN TYPE AC STARTER, WITH PRESSURE REGULATOR AND SINGLE-PHASE MOTOR.

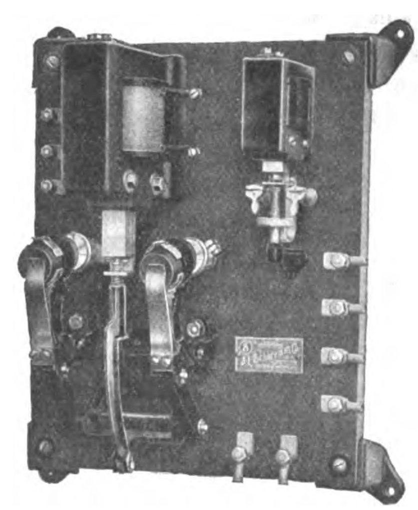
is broken. The opening of this switch then disconnects the motor from the line.

The relay, when closed, completes the circuit of its coil, so that current is carried by the control circuit only at the moments of starting and stopping. As both the starting and stopping operations



SCHUREMAN ALTERNATING-CURRENT TYPE AC STARTER.

are performed by making contact, no current is broken in the control circuit, eliminating arcing on the control switches.

This type of starter finds its widest use in connection with vacuum-cleaning plants using remote push-button or vacuum regulator control and in connection with small air compressors or fluid-pressure pumps. On pump and compressor installations it is used with pressure-regulator control, starting and stopping the motor on the desired limits of pressure.

Westinghouse Company Reorganized.

The Westinghouse Electric and Manufacturing Company has again become the property of the stockholders, after having been in the hands of receivers since the 23d of October, 1907. As stated in the ELECTRICAL REVIEW AND WESTERN ELECTRICIAN last week, the petition for the discharge of the receivers was made on December 5 in Pittsburg, Pa., before Judge Young, of the United States District Court, and was immediately signed by him. The petition was presented by G. B. Gordon, attorney for the receivers and for the Merchandise Creditors' Committee; Paul D. Cravath, attorney for the Stockholders' Committee, and A. H. Larkin, attorney for the Readjustment Committee. Mr. Gordon made the address to the court, in which he gave a statement of the company's affairs prior to the receivership, explained the causes which led to the establishment of the receivership, presented a report of the operation of the company during the tenure of the receivership, and finally led up to the great work which has been accomplished within so short a time by Mr. Westinghouse and the various committees in bringing about the rehabilitation and reorganization of the company. He emphasized the fact that during the year the receivers had been in charge they had not only succeeded in paying off the interest on bonds as it fell due from time to time, but that they also kept the large factories of the company in operation during the entire time, doing an excellent business at a net profit of over $1,000,000.

The action of 5,000 employes in subscribing for $600,000 of stock of the company was another feature presented to the court, which made a great impression, because it demonstrated the amount of confidence the employes themselves had in the company. It was also brought out that the company, under the reorganization, would in every way be in a better condition than at any previous period in its history, as it would start upon the new regime with cash on hand amounting to upward of $15,000,000, with an indebtedness of only about $200,000. Mr. Cravath, in addressing the court on behalf of the stockholders' committee, stated that, in the annals of receiverships, this one stood without a parallel as the most successful.

The board of directors, which consists of George Westinghouse, E. M. Herr, James S. Kuhn, Joseph W. Marsh, William McConway, J. L. Callery, Richard Delafield, Albert H. Wiggin, Charles S. Brooker, A. G. Becker, Charles A. Moore, Edwin F. Atkins, Neal Rantoul, E. C. Converse, Anthony N. Brady and George Verity, held a meeting in New York on December 7 and organized as follows:

President, George Westinghouse.

Temporary chairman of executive committee, E. C. Converse.

First vice-president, E. M. Herr.

Second vice-president, L. A. Osborne.

Acting vice-presidents, G. W. Hebard and W. M. McFarland.

Secretary, Charles A. Terry.

Treasurer, T. W. Siemon.

Assistant treasurers, E. St. John and H. F. Baetz.

Auditor, J. C. Bennett.

Allis-Chalmers Business.

A representative of the Allis-Chalmers Company says business is steadily increasing. The bookings of the company during November were eighty per cent greater than during November, 1907, fifteen per cent above October, and October was sixty-five per cent ahead of September.

Few of the orders were of large size, but they are of a character that suggests that the industrial companies are entering a new era of spending money on small additions and on replacements.

The machinery furnished to the mining and ore-treating companies is of very respectable volume and is increasing steadily.

Turbines and high-pressure fire-fighting apparatus forms a large part of the company's business, and orders for the former and investigations of the performances of the latter are being secured in very gratifying numbers.

A large contract for the construction of a tie-preserving plant for the Pennsylvania Railroad Company was recently secured and is the first installation of a plant of this kind by an eastern trunk line.

A New Rectifier.

An alternating-current rectifier invented by two instructors of the Massachusetts Institute of Technology, Harold G. Crane and Waldo V. Lyons of the Electrical Engineering Department, is now being tested with the purpose of perfecting it for the market. The rectifier has been found satisfactory for such use as the charging of storage batteries, and its economy is declared to assure the success of the new converter.

Auto-Starters for Squirrel-Cage Motors.

It is the usual practice in all squirrel-cage induction-type motors of greater than five-horsepower capacity to employ a starting device of the reactive type, usually termed an "auto-starter," or "starting compensator," the object being to limit the rush of line current according to the load demands. The selection of this device is a very important matter, since even a good motor may be unsatisfactory in starting characteristics if equipped with a poor auto-starter. In fact, excellence in design and construction in any motor may be nullified, in so far as starting characteristics are concerned, unless an auto-starter of proper design is provided.

The auto-starter, made by the Wagner Electric Manufacturing Company, St. Louis, Mo., and shown in the illustrations, is a strong and attractive feature of the motor equipment. In its design and construction no thought or experiment has been spared to produce a practical and effective motor-starting device having the maximum durability.

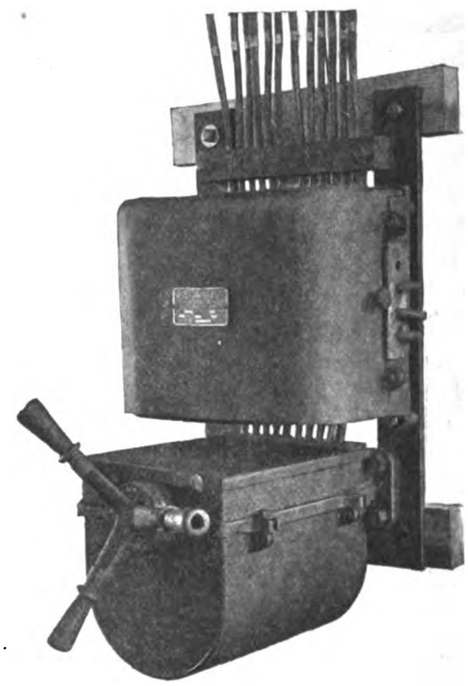


FIG. 1.—WAGNER AUTO-STARTER COMPLETE.

The auto-starter consists of two elements, a transformer enclosed in one iron case, and a switching device enclosed in another case which is oil filled. Brought out from the transformer are a number of sub-voltage taps, giving different percentages of full voltage, and from which any desired tap may be selected for permanent wiring to the switching device, after one or two trials under actual service conditions.

The switching device, as will be noted

from an inspection of Fig. 2, which shows the interior, is of the horizontal-shaft drum type, with the mechanism immersed in oil. A quick-make-and-break cam eliminates all possibility of arcing between the working contacts. In starting the motor, the handle is moved always in the one direction. It may be turned back to the "off" position only from the first starting position, and after once passing the first starting position it cannot be returned to "off" except by going through all of the succeeding positions. The connections for the successive positions are as follows:

In the "off" positions the transformer and motor are both dead. Upon turning the operating handle into the first starting position the motor is connected to the sub-voltage tap of the transformer, with the fuses short-circuited. The connections thus established cause the compensator to deliver sufficient pressure to start the motor with a minimum of line disturbance. Turning the handle to the second position connects the motor to the full voltages and disconnects the transformer, the fuses being still short-circuited. Finally, in the third or full running position the fuses are cut into the circuit.

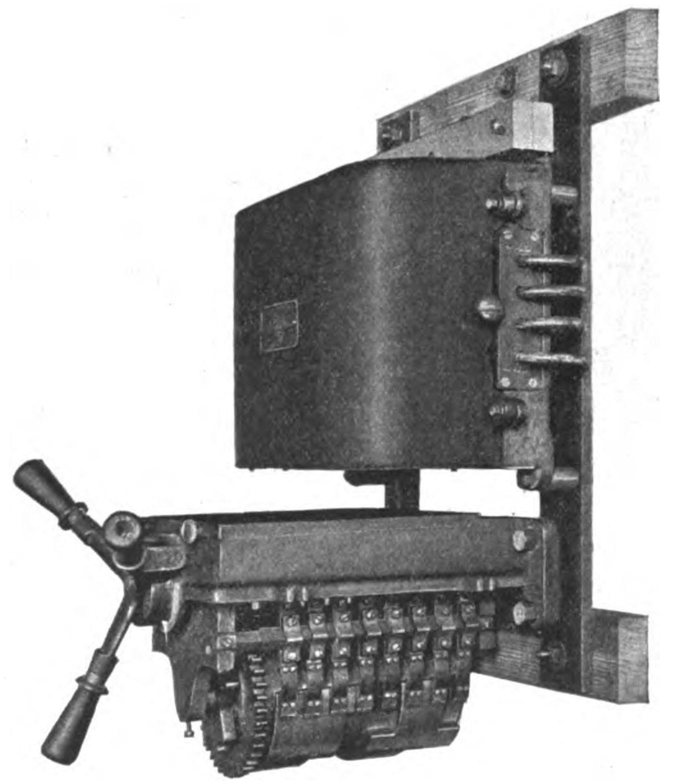

FIG. 2.—WAGNER AUTO-STARTER WITH OIL TANK REMOVED.

The advantages are enumerated as follows:

1. Fuses are short-circuited at starting and first running positions.

2. Transformer is alive with switch upon first starting position only.

3. Motor is disconnected with starter in off position.

4. Motor obtains any desired percentage of voltage according to starting requirements.

5. All make-and-break contacts are of the sliding type and oil immersed.

6. Points of making and breaking of circuit on the drum are separate and renewable.

7. The actual contact points are renewable.

8. All connections are made and broken quickly.

The complete device is of the unit system, a switch and a transformer, and may be arranged to meet best the conditions at the point of installation. The starter is identical as shipped for two or three phase work.

Westinghouse Fixed Charges.

The liability statement of the Westinghouse Electric and Manufacturing Company, as contained in the receivers' report, shows that there are outstanding approximately $36,000,000 bonds and other forms of interest-bearing notes, on which the fixed charges are approximately $4,000,000 a year.

The largest item in this total comprises the five per cent convertibles of $22,135,000. The next in importance is the three-year, six-per cent collateral notes, due August 1, 1910, of which $6,000,000 are outstanding. These latter would seem to be among the earliest obligations to invite retirement, because of the high rate of charge upon them. It is noteworthy also in this collection that the amount of cash on hand on December 4 was greater than one-quarter of the entire outstanding bonds and notes on which fixed charges are reckoned. This does not include $1,525,000 of special cash deposits noted in the receivers' balance sheet.

A FINE STREET-LIGHTING INSTALLATION AT WEST AURORA, ILL.

BY W. R. BONHAM.

The West Aurora Improvement Club, of West Aurora, Ill., which was organized about three months ago for the purpose of improving the business section of the city, has completed its first installation of electric street lamps, and the turning on of the current was an occasion of considerable importance.

It was decided to install multiple tungsten lamps on artistic iron posts, fifteen feet high, and carrying two side-arms, each supporting 100-watt tungsten lamps, at about twelve feet from the ground. A sixty-watt tungsten lamp is placed on the top of the post, and the lamp sockets are supported by the cable conductors, which extend about two inches from the iron support. This method obviates a shock being transmitted to the lamp in case the post should be struck by a passing vehicle. Clear lamps are used, with an eight-inch opalescent globe placed over the lower lamp, and a ten-inch globe over the upper lamp. The posts are placed fifty feet apart, exactly opposite on each side of the street. At street crossings a four-arm post is used.

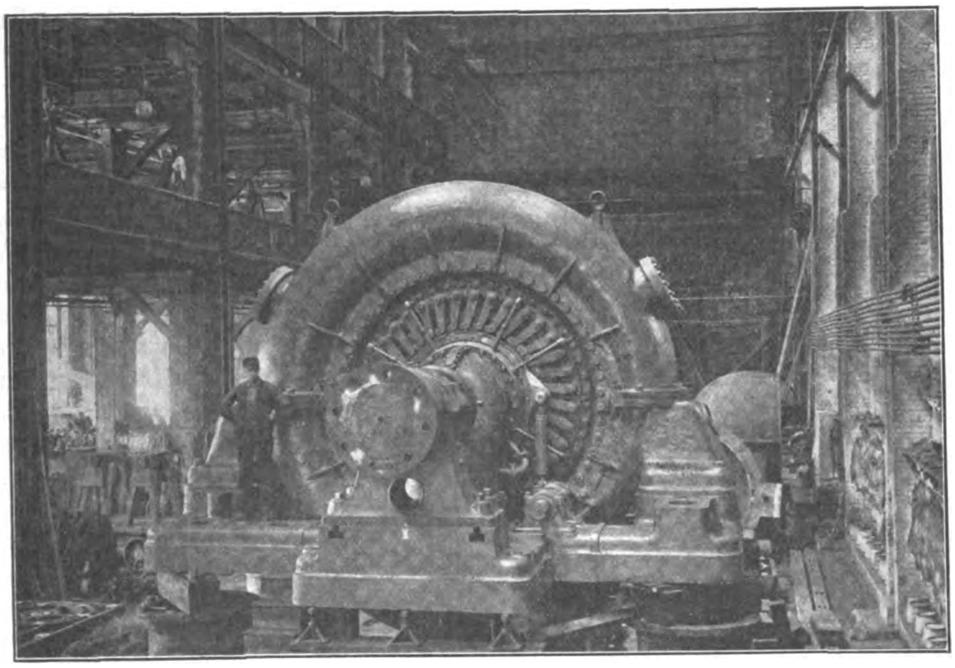
All wires are run in underground conduits, and in the purchase of material and installation, local firms were favored wherever possible. The lamps were purchased from the Sterling Electrical Manufacturing Company, of Warren, Ohio. The installation includes seventy lamp-posts, eight of which carry four cross-arms, and the balance two, providing for 226 lamps. During the entire installation only one lamp suffered breakage, which greatly increased the confidence of the purchasers in the stability and reliability of the tungsten unit.

The president of the club formally presented the installation to the city of West Aurora, which will now maintain it. The acceptance was made by the mayor, and when the current was finally switched on, the greatest satisfaction was manifested.

Two 8,500-Horsepower Allis-Chalmers Water-Wheels for the Telluride Power Company, Grace, Idaho.

In the new waterpower development at Grace, Idaho, of the Telluride Power Company, there are installed two 8,500-horsepower Allis-Chalmers Francis-type water-wheels with double-discharge end horizontal shafts.

The turbines are supplied with water by means of a penstock or pressure pipe five miles long, under approximately 450 feet head, and are required to drive two 5,500-kilowatt, sixty-cycle alternators, whose power at 40,000 volts will be transmitted nearly 150 miles and delivered near Salt Lake City to the electrical distribution system of the Telluride Power Company in Utah.



8,500-HORSEPOWER DOUBLE-DISCHARGE SPIRAL-CORE HYDRAULIC TURBINE, TELLURIDE POWER COMPANY.

Each turbine, when operating at 300 revolutions per minute with an effective hydraulic head of 450 feet, delivers 8,500 horsepower at an efficiency of eighty-four per cent. These units are of the Francis type and consist of a horizontal main shaft carried by two bearings, and a single central casing surrounding a twin runner controlled by a service or "vane" type speed-gate and discharging in opposite directions into two separate draft tubes, all united and supported by an ample bed-plate.

Spiral or scrolltype casings of cast-iron are used with horizontal bottom inlet. The vane shafts are hollow and fitted for forced grease lubrication at both bearings. The runners are of the twin or double-discharge type, and designed to be balanced under running conditions. The draft tubes below the level of the bed-plate are constructed of concrete. The units described are computed to fit the following data: Fall acting on wheel, 450 feet; power at full gate opening, 8,500 brake-horsepower; speed, 300 revolutions per minute.

Electrical Projects on the Pacific Coast.

A number of new corporations have filed articles in the Coast states during the last few days. At Los Angeles, Cal., the Consolidated Reservoir and Power Company has been incorporated with an authorized capital stock of $1,000,000, by H. E. Moore, A. E. Poole, G. I. Lamy, William Lane and others. In Portland, Ore., Goodwin A. Young, Ray W. Lang and N. A. Peery have incorporated the Columbia Railway, Light and Power Company, with a capital stock of $50,000. In Nevada, the interests that are planning to distribute electricity throughout Rhyolite and the neighboring mining camps have organized as the Rhyolite Electric Company, with W. D. Hatton, C. A. Stoible and M. J. Hill of Goldfield, as directors. In San Francisco, the only new incorporation of an electrical nature is that of the Shoenberg Electric Appliance Company, which has a capital stock of $25,000, and of which the organizers are S. G. O. King, S. J. Goldman, M. Shoenberg and H. Shoenberg. The Snow Flake Gold Mining and Power Company has been organized at Salt Lake, Utah, by mining interests in the vicinity of Modena, Utah.

The Griffin Enclosed Gas Engine.

A two-cylinder, three-cycle, enclosed engine has recently been constructed by the Griffin Engineering Company, Limited, of the Kingston Iron Works, Bath, England, designed with a special view to the employment of suction gas as the working agent. This engine possesses a number of original features. By arranging for a scavenging stroke after each explosion, Mr. Griffin is able to use a low compression, and yet get a richer mixture in his cylinder than is possible with even high compressions used with high-speed engines running on the Otto cycle. He claims that he thus combines a low compression with a low consumption of gas per brake-horsepower. The scavenging stroke tends to increase the internal resistance of the engine, but this is compensated for by the use of a special double valve for controlling the supply of gas and air.

Another special feature of the engine is the use of low-tension magneto ignition, a single oscillating magneto firing the charge in both cylinders. Mr. Griffin employs electrical means of breaking the contact, with the result that the magneto used can be fixed at any convenient point of the engine instead of having to be placed in a position giving a straight lead from it for the links to the contact-breaker. Any number of cylinders can, moreover, be fired from the one magneto.

Salt River Reclamation Project.

The Salt River Reclamation Project, involving the construction of the great Roosevelt Dam at Roosevelt, Arizona, is now seventy-four per cent complete, announces the *Reclamation Record*. About 8,500 cubic yards of masonry were laid in the Roosevelt Dam during November, bringing the lowest part of the structure to an elevation of sixty-five feet and the highest part thereof to an elevation of eighty-five feet. About forty-eight per cent of the masonry of the dam had been laid at the close of November. The cement mill, with two kilns running on an average of twenty-one days each, burnt 9,800 and ground 9,500 barrels of cement. The transmission line is completed into Roosevelt, and the setting of poles and stringing of wire is in progress near Phœnix. The foundations for the towers for the Salt River crossing near Tempe are being built. The walls and roof of the switching station are completed. Good progress has been made in the excavation of the South and Grand Canals.

Current Electrical News

CONTINENTAL EUROPE.

(Special Correspondence.)

PARIS, DECEMBER 5.—The telegraph department of France has adopted a new measure which will be greatly appreciated by the public. Starting December 1, steps have been taken to allow the public to send telegrams, in cities where there is a night service, at the greatly reduced rate of one centime (one-fifth of a cent) per word, with a minimum amount of ten cents in any given case. Thus for 10 cents it is possible to send quite a letter containing fifty words. The messages are sent during the night and are delivered in the first mail of the morning. This "letter-telegram" system was approved by the parliamentary postal and telegraph commission about six months ago. The telegraph rates can be paid by placing postage stamps on the telegram.

A French scientist, M. Louis Paris, has succeeded in producing an artificial sapphire by using the heat of the electric arc. Already the ruby has been formed at a high temperature, but for making the sapphire many difficulties were connected with the operation. Alumina and cobalt oxide are melted together, the latter giving the yellow color, and mixed with a small percentage of lime and magnesia. The result is a stone which cannot be distinguished from the natural sapphire except by the microscope.

Line No. 4 of the Paris Metropolitan subway, which runs from the Clignancourt to the Orleans Gates, is expected to be finished during next summer. This work was delayed on account of the large amount of caisson construction needed for the tunnel under the Seine. One-half of the present subway, running northward from the Seine, is now open for regular traffic. Line No. 6, running from Place d'Italie to Place de la Nation, will be delivered to the Metropolitan company by the contractors in February or March of next year. A rolling incline is now being installed in one of the subway stations in the city as an experiment, as in some cases the tunnel lies at a great depth and the public complain of having to mount the staircases. For the same purpose electric elevators will be tried at another of the stations.

We learn that the Nobel Prize for Physics is to be awarded to Professor Lippmann for his work in the photography of colors. It will be remembered that he is also the inventor of the capillary electrometer, which is one of the most sensitive known, and has carried out other researches in the electrical field.

In order to facilitate the exchange of international telephone messages an agreement has been made between the French and the Italian departments by which a person in Paris, for instance, can be informed by telegraph that someone in Rome wishes to telephone him and that he is to take the message in a certain telephone booth at the designated date and hour. Such telegrams are sent at a reduced rate. A. DE C.

GREAT BRITAIN.

(Special Correspondence.)

LONDON, DECEMBER 4.—An extensive system of street lighting by means of metallic-filament lamps is now under the consideration of the Marylebone (London) Borough Council, in substitution for the present lighting by gas. On the contrary, it may be reported that the City of London Corporation has given facilities to the Gas Light and Coke Company to carry on an experiment in public lighting in the well-known thoroughfare of Fleet Street, by means of inverted, high-pressure gas lamps.

Although reciprocating engines were installed in the first portion of the Greenwich Tramways generating station of the London County Council, turbo-generators have been adopted for the second portion which is now building. The tenders for two 5,000-kilowatt steam turbo-generators have just been received, and it is interesting to note that the British Westinghouse Company has received the order at $204,000, the turbines being of the Rateau type. There were lower tenders than the accepted one, and in order to satisfy the Highways Committee as to the working of this type of turbine, the company took the tramways officers of the Council for a trip to Milan.

The Institution of Electrical Engineers is about to lose its secretary, Mr. G. C. Lloyd, who has held his position since 1904, on the death of Mr. W. G. McMillan. Mr. Lloyd has been selected for the post of secretary of the Iron and Steel Institute, where he was assistant secretary prior to 1904.

The recent fire on the City & South London electric tube railway has awakened the fire brigade committee of the London County Council to the fact that several improvements could be made to the fire-extinguishing apparatus on electric railways. Accordingly, they have reported that periodical inspections of the apparatus should be made by the chief fire officers, that the railway company should provide illuminated signs both on the platforms and on the street level showing when the current is switched on, or off, the live rail, and that in the event of a fire, the fire brigade should be sent for. Hitherto, there has been a rule that the railway employes should themselves cope with a fire on a tube railway.

Hitherto, the National Telephone Company has been assessed throughout the country, for taxation purposes, at a certain rate per mile of wire. The company has now, however, accepted the principle of being taxed according to the earning power of its undertaking in the various districts. This will add considerably to the ratable value in many districts, as much as fifty per cent in some, and in a few quarters this is popularly regarded as a satisfactory retaliation for the imposition of the new rates of charging by the company, which have, in the main, turned out to be an increase over the old rates. G.

EASTERN CANADA.

(Special Correspondence.)

OTTAWA, DECEMBER 12.—Application is being made to the Ontario Legislature for an act to incorporate the Eastern Ontario Electric Railway Company. It is proposed to run from Cornwall to Toronto, with a branch from Ottawa to Brockville. Permission is sought to issue bonds at the rate of $25,000 per mile.

The Municipal Council of Brockville, Ont., has entered into an agreement with the Bell Telephone Company, covering a five-year period, by which the company pays the corporation $500 a year rental for the use of its streets and fixes the rate for business telephones at $30 and residence telephones at $25 per year.

It is expected that the city of Peterboro, Ont., will shortly approach the Hydro-Electric Power Commission with regard to electric power. It is proposed to obtain this, if possible, from sources about twenty miles north of the city, and practically the same plan has been worked out as at Ottawa. About 8,000 horsepower will be used by the city at present.

The Sao Paulo Tramway, Light & Power Company, the Brazilian concern owned and operated by Canadian capitalists, has increased its dividend rate from nine to ten per cent per annum. This action was taken by the directors at Montreal last week, when a quarterly dividend of two-and-one-half per cent was declared. The history of the Sao Paulo company, from five-and-three-fourths per cent in 1903, has been one of constantly increasing dividends.

In an official statement issued to shareholders, the Dominion Power and Transmission Company, which owns the street railway and controls all the electric suburban lines entering the city of Hamilton, Ont., explains that one of the chief reasons that the payment of dividends on the stock is suspended is on account of the depressing effect that the Ontario government's power project has had on the sale of securities. The company has to spend $500,000 reconstructing the street railway, but found it almost impossible to sell the securities, and dividend payments have been stopped until the amount is accumulated. Mr. Geo. Blanchard, vice-president of the company, an American street-railway expert, has severed his connection with the company.

It is estimated that the interests which are working to have the Mexican Power-Tramway lease put through, control and have proxies for 110,000 shares of the power company's stock.

The city of Brantford, Ont., will vote in January on debentures for the purpose of establishing a municipally-owned light and power plant. W.

IMPORTANT DEVELOPMENTS.

PLANS TO ILLUMINATE STATUE OF LIBERTY IN NEW YORK HARBOR—Chief Engineer Armstrong, of the Singer Building, of New York, has been in Washington to interest congressmen in a plan to light up the statue of the Goddess of Liberty in New York harbor as the Singer tower is lighted. The plan is to have twenty-four powerful searchlights, situated at the base of the statue, trained on the statue during the night.

ELECTRICITY TO LIGHT THE PYRAMIDS OF TEOTIHUACAN—The representatives of the Mexican Light and Power Company have offered to follow the suggestions made by the president of the republic regarding the furnishing of electric energy for lighting and power purposes in the camping grounds and installations established in the pyramids of San Juan Teotihuacan. To that effect a committee of engineers has been appointed to make a survey in the district of Texcoco to learn whether the owners of private properties within that jurisdiction could establish pumping plants for irrigation purposes, and if the water can be economically used from that place, so as to make the establishment of a central supply of electric energy feasible, the company will undertake the work.

NEW YORK, NEW HAVEN & HARTFORD TO START ON $30,000,000 ELECTRIFICATION—Contracts involving $30,000,000 of improvements by the New York, New Haven & Hartford Railroad, have been arranged for. The railroad is to electrify a six-track line from New Rochelle to One Hundred and Twenty-ninth Street. A tunnel will be built under the East River to Astoria, thence to Long Island City, with another East River tunnel and subway to a huge passenger station to be erected on the block bounded by Fourth and Lexington avenues, Thirty-second and Thirty-third streets. The trackage from Astoria to Long Island City may be underground or may be elevated. A connection with the Pennsylvania will be made in Long Island City, according to the report, and a New York, New Haven & Hartford terminal station will be built on the old Park Avenue carbarn site. This would permit passengers from Boston to pass through New York for the West and South without leaving the train.

ELECTRIC LIGHTING.

(Special Correspondence.)

ST. JOHN, N. D.—Horace Bourassea is constructing an electric-light plant at St. John.

RUSHVILLE, NEB.—D. W. Ferree contemplates installing an electric-light plant at Rushville.

MURRAY, IOWA—A special election will be held at Murray to determine upon lighting the streets with electricity. C.

NORWALK, CAL.—J. R. Gordon has been awarded a franchise for an electric-lighting and power system in the town of Norwalk. A.

WEBB CITY, MO.—An explosion badly damaged the plant of the Independent Power Company, at Webb City, killing one employe.

NEZ PERCE, IDA.—E. G. Ousterhaute and J. F. Englehorn, of Nez Perce, are building a power plant with a capacity of 200 horsepower near Orofino, Ida. A.

TACOMA, WASH.—The commissioner of public works of Tacoma is advertising for proposals to furnish a fifty-arc, air-cooled, constant-current transformer. A.

SAN FRANCISCO, CAL.—An additional $500,000 of the Northern California Power Consolidated 5's has been sold and the proceeds are being invested in the development of the plant.

DELHI, IOWA—An electric light plant costing $18,000 will be installed at Delhi. The town has raised $8,000 and outside capital will supply $10,000. Power will be furnished to small factories. C.

SEATTLE, WASH.—The city of Seattle will vote on December 29 on issuing $800,000 four-and-one-half-per-cent lighting bonds, together with two other bond propositions for ratification or redemption.

ALBANY, N. Y.—The Public Service Commission, second district, has authorized the Rockland Light and Power Company, of Nyack, N. Y., to issue $500,000 five-per-cent thirty-year mortgage bonds.

SEATTLE, WASH.—The City Council of Seattle has passed an ordinance adopting plans and specifications for the enlarging and extending of the municipal light and power system at a cost of about $800,000. A.

VILLISCA, IOWA—The Villisca Electric Company has secured a temporary injunction against the city of Villisca to enjoin the granting of a franchise to F. P. Tyler, who proposes to construct a rival electric-light plant.

PLACERVILLE, CAL.—George L. Threlkel, of Placerville, Cal., has appropriated 10,000 miners' inches of water from the North Fork of the American River in El Dorado County, California, for power purposes. A.

LA GRANGE, CAL.—The work of building a thirty-two-mile transmission line from the plant of the La Grange Power Company, near La Grange, to the town of Turlock, has been begun and is to be completed within three months.

FLORA, IND.—Lincoln Hesler, who appeared before the town board in the interest of William B. LaBaw and Guy W. LaBaw, of Veedersburg, who wish to secure a franchise for building an electric-light plant, was successful in having the franchise drafted by the board.

ST. LOUIS, MO.—The proposed artistic electroliers on downtown streets will be illuminated for the first time on Centennial Day, November 2, 1909, if the plans of the Downtown Lighting Association, organized at a meeting of business men with a committee of the Civic League, at the Mercantile Club, do not miscarry. Tom W. Bennett was elected president of the association; Dan C. Nugent, vice-president, and Thomas H. West, Jr., treasurer. Committees for each street in the district are to be appointed by the executive committee, to enlist all the property holders as members of the association and to superintend the erection of electroliers in conformity with the patterns selected by a committee of the association.

PORTLAND, ORE.—The Portland Railway, Light and Power Company has plans nearly completed for a two-story concrete and brick transmission station, fifty by one hundred feet, at First and Jefferson Streets, Portland.

ELLWOOD CITY, PA.—As a result of the action taken in Council Ellwood will not have a municipal electric-light plant. The vote for a bond issue of $12,000 for repairing the old lighting plant was lost by a single ballot.

SEATTLE, WASH.—G. W. Wilson, of Seattle, has plans under way for a power plant to supply the towns of Bothell and Woodinville in the same state. He has filed a notice of appropriation of water from North Creek for power purposes. A.

PRESCOTT, ARIZ.—M. J. Hickey, Robert Brown and Henry T. Andrews have secured a franchise for an electric-light and power system at Prescott. The ordinance also permits of the building and operating of telephone and telegraph lines in the city. A.

GREEN BAY, WIS.—The Northern Hydro-electric Company of Green Bay will shortly let contracts for the construction of a dam and power house at High Falls on the Peshtigo River in Stephenson County, Mich. The company will develop 7,500 horsepower. C.

MOROCCO, IND.—The Morocco electric-light plant, formerly owned by W. J. Harpole and Company, has been sold to J. C. Carpenter, a prominent electric-light man. It is the purpose of the new owner to improve the plant and install modern machinery. S.

FORT WAYNE, IND.—The city has just taken possession of its municipal plant for street lighting and, finding it has surplus power, desires to sell it to private consumers at eight cents a kilowatt, whereas customers of the traction company pay a net rate of ten cents.

TONOPAH, NEV.—The Nevada-California Power Company, which recently completed three units of its plant near Tonopah, Nev., with a capacity of 23,000 horsepower, has completed preliminary surveys for its Manhattan and Round Mountain extensions as far as Central, twelve miles from Manhattan. From that point separate lines will be run to the two camps. A.

SAN FRANCISCO, CAL.—The Northern California Power Company, Consolidated, of San Francisco, recently organized, has given a deed of trust to the Union Trust Company of San Francisco, to secure a bonded indebtedness of $10,000,000. Most of the new bond issue will be used in taking up the floating and bonded indebtedness of the companies merged into the consolidated company. A.

SAN FRANCISCO, CAL.—The board of public works announces that it will award the contract for turbines and pumps for the proposed power stations of the auxiliary fire-protective system and for two fire boats to the Byron Jackson Iron Works, notwithstanding that the company's bid was about $7,000 higher than that of the D'Olier Engineering Company of Philadelphia. The contract will approximate $120,000. A.

ST. ANTHONY, IDA.—The St. Anthony Light and Power Company has begun the work of connecting its plant at that place with the plants at Teton City and Rexburg. Next spring the company will build a hydro-electric plant at its site on the Teton River for the supplying of the three lighting systems. The power plant will develop 3,000 horsepower and, with the necessary buildings, power lines and connections, will cost about $150,000. A.

PORT ORCHARD, WASH.—Members of a new power company are visiting Port Orchard, Bremerton, Charleston and other towns in Kitsap County with a project to light these towns with electricity. The promoters plan to utilize the power of the Dosewallup River on the west side of Hood Canal, equipping a plant costing $250,000. The members of the company made plans to apply for the right to furnish light and power to the navy yard at ten cents per kilowatt-hour.

BOSTON, MASS.—The Minneapolis General Electric Company has sold to Blodget, Merritt & Co. $1,100,000 first mortgage five-per-cent bonds, due December, 1934. The proceeds will be used for retirement of one-year six-per-cent notes, maturing December 16, 1908, and will fund floating indebtedness which represents costs of permanent additions to property during the past two years. This company controls all the electric lighting and commercial power business in Minneapolis.

EDUCATIONAL.

WORCESTER POLYTECHNIC INSTITUTE—The electrical engineering department of Worcester Polytechnic Institute, Worcester, Mass., is adequately described and illustrated in a handsome little pamphlet published by the Institute. The very complete electrical laboratory and electric test-car equipment make this institution one of the best equipped in the country. Prof. Harold B. Smith is at the head of the department.

PERSONAL MENTION.

MR. H. D. MURDOCK, who has been mechanical and electrical engineer of the Indianapolis & Louisville Traction Company for the past year, at Scottsburg, Ind., has been appointed superintendent of the company.

MR. HOWARD R. SHARKEY, who is well known to the electrical trade, has joined the forces of the Diamond Rubber Company of Akron, Ohio, and will handle its wire in the East, with headquarters at 1876 Broadway, New York city.

PROF. ERNEST RUTHERFORD, director of the physical laboratory of the University of Manchester, England, and PROF. GABRIEL LIPPMAN, of the University of Paris, have received the awards of the Nobel Prizes for chemistry and physics, respectively, in recognition of their distinguished work in scientific discoveries.

MR. FRANK J. SLOAT, general manager of the Ohio Traction Company, the largest interurban system in Ohio, has resigned to take up mining operations in California. Mr. Sloat has operated all the Schoepf syndicate's properties in southern Ohio for years, and was formerly president of the Ohio State Interurban Association. S.

MR. LOUIS A. FERGUSON, president of the American Institute of Electrical Engineers, and vice-president of the Commonwealth Edison Company of Chicago, was the speaker of the evening at the December dinner and meeting of the Electrical Engineering Society of the Massachusetts Institute of Technology, Boston, December 9. Mr. Ferguson is a graduate of the Tech class of 1888.

OBITUARY.

MRS. ELIZA McGUIRE HAASE, who died December 8, was the mother of Allen Lee Haase, the well-known representative of the Harvard Electric Company, Chicago.

MR. MYRON T. WILBUR, treasurer of the American District Telegraph Company and of the Western Union Telegraph Company, died on Tuesday, December 8, at his home in New York city, after an illness of ten days. Mr. Wilbur was sixty-two years of age and is survived by Mrs. Wilbur, his widow. He was in every respect a fine man, with a host of warm friends and close acquaintances, who with us will deeply deplore his passing.

NEW MANUFACTURING COMPANIES.

HORNELL, N. Y.—The A. J. Deer Company has been incorporated to manufacture motors, electric novelties, electric machinery, dynamos, etc. Capital, $120,000. Incorporators: A. J. Deer, Buffalo; F. Bartz, F. A. Wygant, Hornell.

ALBANY, N. Y.—The Butler Electric Clutch Company, of Yonkers, has been incorporated with a capital of $50,000. The directors for the first year are as follows: Wm. W. Butler, Martin E. Thew and Clarence Alexander, of Yonkers.

NORFOLK, VA.—The Virginia Auto-Electric Piano Company, of Norfolk, has been incorporated with D. E. Levy, president, and Moe Levy, secretary and treasurer. The capital stock is placed at $5,000 to $15,000, and the company will manufacture pianos.

ROCHESTER, N. Y.—The Iternational Telechronometer Company, Rochester, has been formed to execute electrical work of all kinds. Its capital is $500,000, and incorporators are George S. McMillan, James W. Lewis, Clarence W. McKay, Merton E. Lewis, Rochester, and Victor B. Deyber, Albany.

MINNEAPOLIS, MINN.—The Northern Electrical Company and the Electrical Engineering Company, both of Minneapolis, have been merged, James Richardson, president, and W. E. Stephenson, manager, of the former company, having bought G. W. Hayford's interest in the latter. The officers of the consolidated company are: Morgan Brooks, president; James Richardson, vice-president, and W. E. Stephenson, secretary and treasurer. The business will be continued at 21 Sixth Street. C.

PROPOSALS.

POSTOFFICE AT WARREN, OHIO—The office of the Supervising Architect, Washington, D. C., will receive sealed proposals until January 12 for the construction (including plumbing, gas piping, heating apparatus, electric conduits and wiring) of the United States Postoffice at Warren, Ohio, in accordance with specifications, which may be had from the custodian of site at Warren, or at the office of the Supervising Architect.

STATE CAPITOL OF KENTUCKY—Sealed proposals will be received at the office of the Board of State Capitol Commissioners at Frankfort to January 5 for the manufacture and installation of the electric-light fixtures required in the new State Capitol Building, Frankfort. Plans and specifications for the work may be seen at the offices of the architects, Frank M. Andrews & Company, Cincinnati, Ohio, and Waldorf-Astoria, New York city. Bids must be addressed to Edward M. Drane, secretary Board of State Capitol Commissioners, and must be accompanied by certified check for at least five per cent of the amount of the bid.

ELECTRICAL SECURITIES.

Although the markets have continued irregular, increased activity has been the rule, and the general price movement has been upward. The average price of railroad shares made a new high level for the year and the industrial average also registered a good advance. Public buying was more active, and this is contrary to general expectations. For the first time since election there has been a genuine concession in quarters which were heretofore pessimistic regarding the increasing business revival. The declaration of the first dividend on its preferred stock by the Wisconsin Central, and the increase in the dividend rate of the Western Union, were minor factors in bringing about increased confidence in the financial community.

Dividends have been declared upon the following electrical securities: Reading Traction Company; regular quarterly dividend of seventy-five cents a share, payable January 1 to stock of record December 11. United Gas Improvement Company; regular quarterly dividend of two per cent, payable January 15 to stock of record December 31. Regular quarterly dividend of one-and-one-half per cent on the preferred stock of the Duluth Edison Electric Company, payable on the first day of January, 1909, to stockholders of record at the close of business on December 12. Manhattan Railway Company; regular quarterly dividend of one-and-three-fourths per cent, payable January 1. Union Traction Company, Philadelphia; semi-annual dividend of three per cent, placing the stock on a six per cent per annum basis. The stock has heretofore been on a five per cent per annum basis. The dividend is payable January 1 to stock of record December 10. Semi-annual dividend of $3 per share on the preferred stock of the Columbus Electric Company, payable January 1, 1909, to stock of record December 21, 1908. Canadian General Electric Company, Limited; regular quarterly dividend of one-and-three-fourths per cent on its common stock, payable January 1. Books closed December 14, reopen January 1. Central District and Printing Telegraph Company; regular quarterly dividend of two per cent, payable January 20 to stock of record January 23. Bangor Railway and Electric Company; quarterly dividend of one-and-one-fourth per cent, payable January 1 to holders of record December 20. El Paso Electric Railway; a dividend of three per cent on the preferred, payable January 11 to stock of record December 30. Halifax Electric Tramway; a dividend of one-and-one-half per cent, payable January 2. Lynchburg Traction and Light Company; one-and-one-half per cent, and an extra dividend of one per cent, payable December 15. Portland (Ore.) Railway, Light and Power Company; a dividend of one-and-one-fourth per cent, payable January 2. Sao Paulo Tramway, Light and Power Company; quarterly dividend of two-and-one-half per cent, payable January 2. Union Passenger Railway, Philadelphia; semi-annual dividend of $4.75, payable January 1. West Philadelphia Passenger Railway; semi-annual dividend of $5, payable January 1.

TELEPHONE AND TELEGRAPH.

(Special Correspondence.)

HOLLIS, OKLA.—The Hollis Telephone Company has been incorporated with a capital stock of $20,000. P.

DALLAS, S. D.—The Tripp-Myer Telephone Company has been incorporated with a capital stock of $10,000.

WARSAW, IND.—The Commercial Telephone Company is in the market for material to construct a new circuit, six miles in length. The line is to be completed by January 15. S.

FARGO, N. D.—The agreement for exchanging local and long-distance service in North Dakota between the Independents and the Bell company has resulted in a revision of rates which amounts to an advance. C.

SHIRLEY, IND.—The Farmers' Mutual Telephone Company, of Shirley, has been sold with all rights, property and franchises, to H. N. Rhorer, of Greenfield, Mo. The new owner is an experienced telephone man and says that he will remodel, re-equip and extend the plant. S.

INDEPENDENCE, CAL.—The board of supervisors of Inyo County, California, is advertising for bids for a telephone franchise to connect the towns of Independence, Lone Pine, Keeler, Darwin, Ballarat and Skidoo with a telephone line. Bids will be received until January 5. A.

SAN FRANCISCO, CAL.—J. C. Rohlfs, manager at San Francisco for the marine department of the Standard Oil Company, has arranged to equip the company's steamers Atlas, Asuncion and Maverick and barge 91 with the United Wireless Telegraph Company's system of wireless telegraph apparatus. A.

SEATTLE, WASH.—The Pacific States Telephone and Telegraph Company, of San Francisco, is planning the expenditure of about $600,000 on its system at Seattle. The improvements include a new telephone exchange in the Beacon Hill district, the laying of permanent underground conduits and the placing of other equipment. A.

MINNEAPOLIS, MINN.—Toll coupons for long-distance service, which are sold at a discount, are held to be illegal as being discriminatory, under the state anti-pass law of Minnesota, according to an opinion by the attorney-general's department. The Tri-State Telephone Company refuses to accept the ruling and may not withdraw them without further investigation. C.

HONOLULU, H. I.—Clinton J. Hutchins, of San Francisco, who is manager of the Island Wireless Telegraph Company, of Honolulu, has placed a contract with the Automatic Electric Company, of Chicago, for automatic telephones and will put in a telephone system in Honolulu. The company already holds franchises under which the work can be done. An application has been made to increase the capital stock of the company from $150,000 to $1,000,000, and to change the name to the Hawaiian Telegraph and Telephone Company. The Honolulu system will be operated in connection with the company's inter-island wireless system. Mr. Hutchins' plans also include the building of a $50,000 central exchange and office building on a site recently purchased in Honolulu. A.

ENGINEERING SOCIETIES.

STEVENS ENGINEERING SOCIETY—The American Society of Mechanical Engineers has established its first student section by affiliating with itself the Stevens Engineering Society of Stevens Institute of Technology, Hoboken, N. J. It is believed that other student organizations will be similarly favored. Though these undergraduate associations will retain their personnel and autonomy, it is expected that both the allied societies as well as the American Society of Mechanical Engineers will benefit from this closer contact of the engineer and the engineer-student.

FT. WAYNE ELECTRO TECHNIC CLUB—One of the most profitable meetings of the Electro Technic Club of Ft. Wayne, Ind., organized from among the employes of the Ft. Wayne Electric Company, was held December 1. The principal address was made by Prof. J. W. Esterline of Purdue University on "The Commercial Testing of Raw Material." Professor Esterline confined his discussion of the subject particularly to materials entering into the manufacture of electrical apparatus and cited many instances of the necessity for tests he found in his work as consulting engineer for a umber of Indiana cities in the installation of electric-light and power plants. S.

DATES AHEAD.

American Roentgen-Ray Society. Annual meeting, New York city, December 28-30.

American Association for the Advancement of Science. Annual meeting, Baltimore, Md., December 28-January 2.

Chicago Electrical Show. Coliseum, Chicago, Ill., January 16-30, 1909.

Northwestern Electrical Association. Annual meeting, Milwaukee, Wis., January, 1909.

American Association of Electric Motor Manufacturers. Next meeting, January, 1909.

LEGAL NOTES.

Conducted by J. L. Rosenberger, LL.D.

SUFFICIENT FULFILLMENT OF DUTY IN FURNISHING OF CONTROLLER—An electric passenger-carrier fulfills its duty, so far as the controller of an electric car is concerned, the Supreme Court of Minnesota holds, Jenkins vs. St. Paul City Railway Company, 117 Northwestern Reporter, 928, if the controller is shown to have been of standard character, made by a reputable manufacturer, in good condition, and to have been subjected to such inspection as is reasonable and practicable. The carrier is required to inspect with adequate care, but not to dismantle complicated machinery for purposes of inspection. In this case, the plaintiff, a man of at least ordinary intelligence, an instructed and experienced motorman, was injured while operating an electric car at a terminal where the cars turned round a loop. The car ran upon the curve of the loop at full speed and was derailed and capsized. The issue was whether a shock of electricity, passing through the plaintiff from his left hand, on the handle of the controller, and through his foot, resting upon a metallic part of the car, produced temporary paralysis, by reason of which he was deprived of control of his car. The court holds that the presumption of negligence conceded from the happening of the accident was rebutted by affirmative testimony, among other things, as to the safe use of the car for twenty days before and months after the occurrence of the accident, during which the car was shown to have been in the same condition as at the time of the accident, and by facts shown as to its purchase and inspection.

ELECTRIC LIGHT AND POWER COMPANY NOT LIABLE FOR INJURY TO BOY IN HOT-WATER WELL—In an open space adjoining an electric light and power station, and about sixty-two feet from the street, was an alleged defectively-covered hot-water well, into which a boy of thirteen fell. For the purpose of bringing himself within the class of cases decided by the courts imposing a higher degree of care upon persons having upon their premises structures or others things which are calculated to attract children, he said "the machinery, being constantly in motion, is calculated to attract and allure the boys, etc., to see the machinery." But the Supreme Court of North Carolina holds that it was error to overrule a demurrer to the complaint based upon the failure of the plaintiff to allege any facts showing that the company owed him any duty in relation to placing, using, or covering the wells upon its premises. The court says, among other things, Briscoe vs. Henderson Lighting and Power Company, 62 Southeastern Reporter, 600, that one may well use a portion of his private lot as an alley for domestic purposes, or a manufacturing establishment, or, as in this case, an electric-light plant, for uses connected with his or its business, without subjecting it to a public use. Of course, if, so used, its servants or others who are invited or entitled to pass over it are injured by pitfalls or obstructions placed there, the owner of the premises is liable. The present case illustrates the fallacy of the theory of implied invitation. Would it ever occur to any reasonable mind that constructing the building with large windows and doors, placing in it the engines, dynamos, and other machinery, and keeping them constantly in motion, for the purpose of discharging its corporate functions and duties, however attractive to small boys, was an invitation to them to make the premises a playground? To adopt the suggestion carries us too far afield for the practical affairs of life, and violates manifest truth. It must be conceded that the liability for injuries to children by reason of dangerous conditions on one's premises is recognized and enforced in cases in which no such liability accrues to adults. But, in the court's view, the defendant company did not owe any duty to the plaintiff to cover the well at all, as it was under no obligation to anticipate that he would come upon its premises. If, as the court holds, he was an unexpected trespasser, and not within the exception to the general rule, it was his duty to look out for danger, and not the duty of the defendant to provide against danger. If the municipal authorities deem the conditions described as dangerous to the public, they may require the owners to guard or fence the premises. In this way the conditions are met without imposing unreasonable burdens upon property owners.

ELECTRIC RAILWAYS.

(Special Correspondence.)

GREAT FALLS, MONT.—An electric line from Great Falls to Choteau is projected. C.

INDIANAPOLIS, IND.—The Indianapolis Traction and Terminal Company is in the market for about fifty new and modern street cars. S.

TOLEDO, O.—The annual meeting of the Toledo Railways and Light Company will be held in Toledo on January 21. Books close January 9 and reopen January 22.

CHICAGO, ILL.—The Chicago & Northwestern Railroad has contracted for sixty miles of electric-block signaling, to complete the equipment of its double track from Chicago to the Missouri River.

DUBUQUE, IOWA—The name of the Dubuque-Platteville interurban road of Dubuque has been changed to the Dubuque, Iowa & Wisconsin Railway, and it is authoritatively stated that the road will be built. C.

BOSTON, MASS.—The Connecticut Valley Street Railway has filed a petition with the Massachusetts secretary of state asking authority from the Legislature to issue bonds for refunding or paying current indebtedness.

SAN DIEGO, CAL.—The San Diego Electric Railway Company has taken preliminary steps to create a bonded indebtedness of $5,000,000, for the consolidation of existing debts and for betterments and extensions. A.

BILLINGS, MONT.—The business men of Billings have taken up the proposition to build an electric line to Laurel, Mont., and will attempt to secure $100,000 subscriptions to the stock of the Billings & Cook City Railway Company. C.

PHILADELPHIA, PA.—There have been listed on the Philadelphia Stock Exchange $6,966,000 first consolidated mortgage five-per-cent thirty-year bonds of the Fort Wayne & Wabash Valley Traction Company, due March 1, 1934.

NEW YORK, N. Y.—Within the next sixty days the New York Central Railroad Company will begin the work of electrifying the present two tracks of the Harlem division from Wakefield to White Plains, a distance of about twelve miles.

BROWNSTOWN, IND.—The county commissioners have ordered a special election to be held in Brownstown and Jackson townships, January 11, to vote upon the matter of a subsidy in aid of electric lines between Brownstown and Seymour, to connect at the latter place with the Indianapolis & Louisville traction line. S.

GOLDFIELD, NEV.—The Esmeraldo County commissioners have granted a franchise to George Wingfield, L. T. Merwin and Thomas F. Manning of Goldfield for an electric railway through the streets of Goldfield and Columbia; the lines will also be extended to Diamondfield, hauling both passengers and freight. Work must commence within sixty days.

OAKLAND, CAL.—Randall, Trowbridge and Company, of Oakland, Cal., have applied for a fifty-year franchise for an electric-railway system covering the principal streets of the town of Vallejo, on the north side of San Francisco Bay. The application declares that if the franchise is secured work will begin within one year and be finished within two years. A.

MAYSVILLE, IND.—A number of capitalists interested in the construction of an interurban line from Bryan, Ohio, to Fort Wayne, Ind., via Maysville, held a meeting December 8. Messrs. Tenniss and Doan, of Philadelphia, who are backing the project, were present and explained in detail the plans and aims of the company. Springfield Township has voted a $10,000 subsidy in aid of the construction of this road, the work to begin early in the spring. S.

TOLEDO, OHIO—It is expected that within a year an interurban railroad will be in operation between Columbus and Toledo. It is thought the construction will be resumed early in the spring on the middle section known as the Findlay-Marion Line. Findlay business men have agreed to take $100,000 worth of stock, and those of Mt. Blanchard will take $20,000, while another $100,000 has been subscribed by the merchants of Marion. The Findlay-Marion line will connect for Toledo with the Toledo Urban and Interurban at Findlay, and with the Columbus, Delaware & Marion traction line at Marion. H.

DWIGHT, ILL.—In order to meet trolley competition and to determine by a fair trial the results of the operation of a coach on a frequent schedule, the Chicago & Alton Railroad has determined to put in operation a motor-car passenger service between Alton and Dwight, a distance of fifty miles. If this experiment is satisfactory the service will be extended to other points. The equipment to be used is a Strang gas-electric motor car, a counterpart of the car which made the run from the Atlantic to the Pacific coast via Toledo, several years ago. The motor is the invention of W. B. Strang, who built the Detroit & Toledo Shore line. H.

CHICAGO, ILL.—Traffic of the three principal local elevated railroad companies in November shows only a slight change in the direction of improvement, which would indicate there has been some increase in general business of the city. Metropolitan's decrease in its daily average traffic was 10,074 passengers compared with a year ago. In the preceding month the road's decrease by similar comparison was nearly 14,000 passengers a day. South Side's November traffic shows a loss of 2,785 passengers a day compared with a year ago, while in October the decrease was more than 4,000. Northwestern maintains its gain over a year ago, due largely to the fact that the Evanston branch of the road was not in operation a year ago. The November increase, compared with last year, was 10,153 passengers a day; in October the gain was 9,204 passengers.

INDUSTRIAL ITEMS.

THE NERNST LAMP COMPANY, Pittsburg, Pa., shows a number of attractive illustrations of Nernst installations in the current number of *Lux*.

THE BUFFALO SPECIALTY COMPANY, Buffalo, N. Y., is offering an Elgin gold watch as a premium to those who order, on sixty days' time, a sixty-pound drum of electric belt dressing.

THE HILL CLUTCH COMPANY, Cleveland, Ohio, has published a supplemental catalogue describing and listing its friction-clutch pulleys and couplings, together with the necessary accessories and extra parts.

THE STANDARD ROLLER BEARING COMPANY, Philadelphia, Pa., under date of December 1, issues Catalogue 24, which is especially complete in listing the many types of ball and roller bearings manufactured by this company.

THE BABCOCK & WILCOX COMPANY, New York, has purchased from the Rust Boiler Company its patents and plant located at Midland, Pa., and will continue the manufacture at that point of the Rust water-tube boiler.

THE WESTERN ELECTRIC COMPANY, Chicago, Ill., has arranged pamphlets containing useful and valuable instructions for the installation and operation of its Design E and Design L generators and motors. The instruction booklets are very completely illustrated.

THE WESTERN ELECTRIC COMPANY, Chicago, Ill., is distributing a new bulletin devoted to its three-wire generator. This generator has only one slip ring, and no auxiliary apparatus is necessary for its operation. Copies of this bulletin will be furnished to those interested upon request.

THE METROPOLITAN ELECTRICAL SUPPLY COMPANY, Chicago, Ill., is making extensive improvements in its office and shelving. The business of this company is on the steady increase, and with its added facilities it will be better prepared than ever to make prompt and careful shipments of all orders.

THE MODEL GAS ENGINE WORKS, Peru, Ind., has an instruction pamphlet entitled, "How to Burn Less Coal," in which it is shown that two-thirds of the coal burned under a boiler is uselessly wasted. The use of gas engines is advocated. The Model Gas Engine Works manufacture gas engines and equipment for a number of purposes and operating on a variety of fuels.

THE YALE & TOWNE MANUFACTURING COMPANY, New York, makers of Yale locks, builders' hardware, chain blocks and electric hoists, has just issued its chain block catalogue, describing its line of chain hoists, both hand and electric, and also trolleys, trolley tracks, etc. This is a rather more expensive and carefully considered production than any of the company's previous books.

THE PETTINGELL-ANDREWS COMPANY, Pearl Street and Atlantic Avenue, Boston, Mass., is distributing a handsome booklet devoted to an exposition of its inexpensive and attractive reading lamps. This booklet should be of particular interest at this time in view of the possibility of selecting these goods for the holiday season. The typographical appearance of the booklet is worthy of extra mention, and the cover paper, which was imported from Italy for this production, adds greatly to the attractiveness of this little souvenir.

THE NEW PROCESS RAW HIDE COMPANY, Syracuse, N. Y., manufacturer of New Process pinions and cut gears, is constructing a considerable addition to its present plant. The company is now working its factory nights to meet orders with its present plant and force. The new addition, which is under construction, will consist of two stories and a basement, sixty feet by eighty feet, adjoining the present plant. The building is to be of steel and brick with cement floors and will increase the available floor space by over 13,000 square feet. The cost complete will be about $30,000. The company has machinery on order for delivery during the next two months approximating $12,000. This comprises principally automatic turret lathes, bevel gear planers and grinding machines An additional hardening furnace for treating automobile transmission gears and drive gears will also be installed. The company reports the total of the orders at present on its books to be in excess of any time in its history.

THE NATIONAL METAL MOLDING COMPANY, Pittsburg, Pa., has met the increasing demand for a metal molding, neat in construction and easy to install, with the production of National metal molding. This molding consists of two pieces, a base and capping. The base is furnished with countersunk holes to accommodate screws or bolts to fasten same securely to walls or ceilings. After the base and base fittings are installed and the wires laid in, the capping is "snapped on." Various fittings are supplied. National metal molding, attachments and tools are explained in full in a booklet just issued by the National company.

DOSSERT & COMPANY, 242 West Forty-first Street, New York city, announce that they have received an order from the Chicago City Railway Company for seventy-five special solderless two-way connectors for 1,000,000-circular-mil cable, and also an order for a large quantity of strain clamps for 750,000-circular-mil cable and solderless two-way connectors for 1,500,000-circular-mil cable from Goliatly & Company, Pittsburg, Pa. They have also received orders from the United Electric Light and Power Company of New York city for a large number of standard and special solderless connectors for use in its One-Hundred-and-Forty-sixth Street substation.

THE TRIUMPH ELECTRIC COMPANY, Cincinnati, O., manufacturer of Triumph electric light and power machinery, announces the following sales recently made: Greenpoint Metallic Bed Company, Greenpoint, L. I., one 200-kilowatt generator and twenty motors, ranging from ten to thirty horsepower and aggregating 400 horsepower; Rapid Motor Vehicle Company, Pontiac, Mich., one 100-kilowatt engine-type generator; Lake Erie Provision Company, Cleveland, O., one fifty-kilowatt engine-type generator and one seventy-five-kilowatt engine-type generator; Lamb-Fish Lumber Company, Charleston, Miss., one 125-kilowatt engine-type generator; Rehbun Last Company, Cincinnati, O., one 100-kilowatt engine-type generator; Robert Mitchell Furniture Company, Cincinnati, O., one seventy-five-kilowatt engine-type generator.

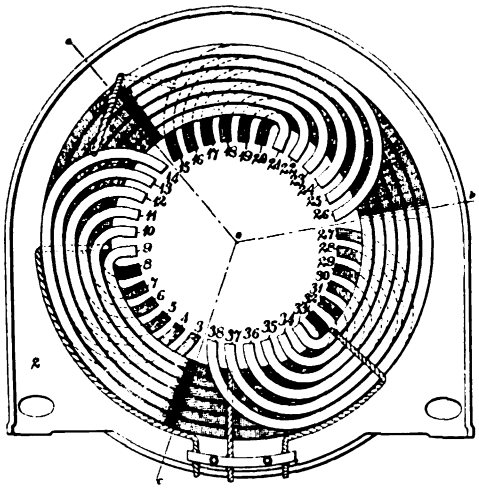
RECORD OF ELECTRICAL PATENTS.

Issued (United States Patent Office) December 8, 1908.

905,827. INGOT-STRIPPER. Henry Aiken, Pittsburg, Pa. Filed September 18, 1905. Has a movable crane carriage, a cylinder and a plunger suspended therefrom and a pump and an auxiliary electric motor mounted thereon.

905,837. ELECTROLYTE. Edward C. Broadwell, Chicago, Ill., assignor to J. W. Meaker, Jr., Chicago, Ill. Filed August 20, 1906. Contains zinc sulphate and zinc naphthalene disulphonate.

905,848. ELECTRIC-MOTOR-CONTROL SYSTEM. William Cooper, Wilkinsburg, and Olof A. Sandborgh, Swissvile, Pa., assignors to Westinghouse Electric and Manufacturing Company. Filed January 3, 1906. In combination with a number of dissimilar electrically-operated car-motor-control systems are means for effecting their concurrent operation.



905,900.—ARRANGEMENT OF END CONNECTORS OF A STATOR WINDING.

905,854. TESTING SYSTEM FOR TELEPHONE LINES. William W. Dean, Chicago, Ill., assignor to Kellogg Switchboard and Supply Company, Chicago, Ill. Filed June 29, 1903. The connection of a high-resistance testing device with each cord circuit is controlled through contacts of the listening key and supervisory relay.

905,868. COIL SUPPORT FOR DYNAMO-ELECTRIC MACHINES. Israel L. Griffith, Pittsburg, Pa., assignor to Westinghouse Electric and Manufacturing Company. Filed June 28, 1905. A supporting bracket has a number of divergent arms to engage insulating strips.

905,874. AIR-COOLING DEVICE. George W. Haverstick, St. Louis, Mo. Filed November 29, 1907. Electric fans are placed adjacent the opposite ends of a casing containing troughs arranged horizontally and means for throwing a spray of water into the troughs.

905,875. CAR-TESTING DEVICE. Albert B. Herrick, Ridgewood, N. J. Filed May 31, 1905. An electrical testing device contains instruments for measuring the resistance of a circuit and for measuring its insulation.

905,889. COIL-SUPPORT FOR DYNAMO-ELECTRIC MACHINERY. Benjamin G. Lamme, Pittsburg, Pa., assignor to Westinghouse Electric and Manufacturing Company. Filed June 28, 1905. Relates to further details for the device covered by No. 905,868.

905,900. WINDING FOR DYNAMO-ELECTRIC MACHINES. George R. Maxwell, Pittsburg, Pa., assignor to Westinghouse Electric and Manufacturing Company. Filed June 16, 1905. Renewed April 10, 1908. A number of groups of coils are provided with similar groups of end connectors, the main portions of which are located in parallel planes and overlap each other.

905,905. ELECTRIC CUT-OUT AND HOLDER. Thomas E. Murray, New York, N. Y. Filed March 13, 1908. The holder has two recesses, circuit terminals disposed therein and a cut-out in loop form having its ends constructed to enter the recesses.

905,907. TRANSMITTER BRACKET. Ernest S. McLarn, New York, N. Y., assignor to Western Electric Company, Chicago, Ill. Filed June 10, 1908. The bracket consists of sheet metal provided with bosses, between which the transmitter arm is supported and pivoted.

905,922. ELECTRICAL APPARATUS. Karl C. Randall, Edgewood Park, Pa., assignor to Westinghouse Electric and Manufacturing Company. Filed April 5, 1907. A transformer, a circuit interrupter and a protective device are mounted in an oil tank.

905,930. TWO-PHASE ALTERNATING-CURRENT DISTRIBUTION. Herbert S. Russell, Hanwell, and Frederick E. Berry, West Drayton, England. Filed May 6, 1907. A booster transformer has its boosted winding in the common return and its two primary windings connected respectively between the separate phase conductors and the common return.

905,933. ELECTRIC-CIRCUIT MAKING AND BREAKING DEVICE. John Ryan, Columbus, O. Filed June 8, 1907. A rotative shaft carries a number of metallic segments over which ride a number of pivoted metallic arms.

905,934. ELECTRICITY METER. Gustave A. Scheeffer, Indianapolis, Ind. Filed January 15, 1907. An armature formed of three coils is locked and manually interlocked on the armature spindle.

905,935. SPARKER DEVICE. Erich Schietzel, Wilkesbarre, Pa. Filed January 8, 1908. A set of three contacts is carried by a plunger normally engaged by a core of the electromagnet.

905,940. HIGH-TENSION INSULATOR. Guido Semenza, Milan, Italy. Filed February 5, 1906. The top section has a wide, flat rim, below which is another rim and between them an intermediate socket and spigot distance piece.

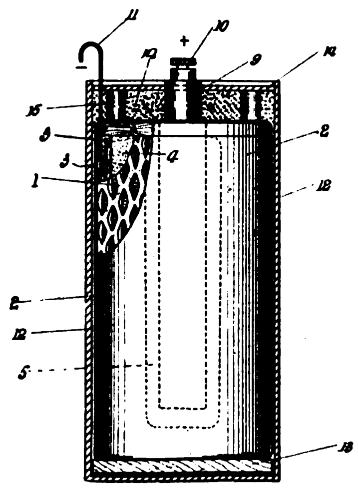
905,952. GALVANIC CELL. Joseph T. Szek, London, England. Filed September 23, 1907. A dry battery contains an expanded sheet-zinc electrode in electrical contact with the casing.

905,964. ELECTRIC-MOTOR SUSPENSION. John E. Webster, Pittsburg, Pa., assignor to Westinghouse Electric and Manufacturing Company. Filed April 12, 1907. A single-phase car motor is mounted on a coiled spring suspension with a quill enclosing the axle of the truck.

905,966. PROCESS AND APPARATUS FOR TESTING WATTMETERS. Edgar M. Wilkins, Mexico, Mexico. Filed August 12, 1907. Involves a method of arranging a photographic shutter for observing the spot on the disc at predetermined intervals.

905,969. ELECTRIC TERMINAL POST. Asbury G. Wilson, Wilkinsburg, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Filed October 10, 1907. A pair of spring jaws partially encloses a cylindrical carbon contact.

905,971. SYSTEM FOR ELECTRICAL DISTRIBUTION. Joseph L. Woodbridge, Philadelphia, Pa. Filed November 13, 1907. Associated with a rotary converter is an alternator connected between it and the alternating-current source and developing an electromotive force at right angles to that of the converter.



905,952.—DRY BATTERY.

905,976. TROLLEY-WIRE HANGER. William S. Arnold, Lorain, Ohio. Filed June 18, 1908. The supporting member has a socket portion and hooks adapted to receive a spanner.

905,995. ALTERNATING-CURRENT MOTOR. Ernst Danielson, Stöpsjön, Fogdhyttan, Sweden, assignor to General Electric Company. Filed June 24, 1907. A motor for three-phase operation has a winding connected with two equal phases and a transformer adapted for T-connection with the two phases to produce a balanced three-phase voltage.

905,998. ELECTRIC OUTLET BOX. Conrad J. Dorff, Chicago, Ill., assignor to Frederic Greer, Chicago, Ill. Filed June 22, 1907. Has an opening in which lies a plug, portions of which are bent to overlie the edges of the opening.

906,003. INSULATOR PIN. Charles G. Ette, St. Louis, Mo., assignor to Ette Investment Company, St. Louis, Mo. Filed January 15, 1908. A metallic pin is provided with a screw-threaded head having a longitudinal slot containing a piece of yielding material.

906,011. PRECIPITATING APPARATUS. John E. Greenawalt, Denver, Colo. Filed April 3, 1905. In a series of cells a mass of metal shavings is supported by a perforated false bottom forming the cathode, the anode being suspended on the top in a porous jar.

906,012. RAILWAY SWITCH AND SIGNAL APPARATUS. Lawrence Griffith, Yonkers, N. Y., assignor to Federal Signal Company. Filed September 20, 1905. In an electric apparatus for operating switches and signals there are a number of electrically-governed motion plates and a controlling device therefor.

906,021. CAR FOR BONDING RAILS. Albert B. Herrick, Cleveland, O., assignor to the Electric Railway Improvement Company, Cleveland, O. Filed March 25, 1905. A part of the floor can be lowered to near the rails and carries means for making electrical contact with them.

906,026. DISTRIBUTING-ARM FOR HIGH-TENSION MAGNETOS. Theodore Hubert, New York, N. Y., assignor to Charles F. Splitdorf, New York, N. Y. Filed October 17, 1907. Comprises a block of fibre, an enclosing tube and a post and contact secured to the block.

906,038. TROLLEY-CONTACT. Andrew R. K. Lauder, Schenectady, N. Y., assignor to General Electric Company. Filed March 27, 1908. A long, flat strip of conducting material is supported directly above, but separated from the trolley wire so as to be engaged by the rims of the wheel flanges.

906,055 and 906,056. AXLE-LIGHTING SYSTEM. Alexander McGary, La Grange, Ill., assignor of one-fifth to Charles Gilbert Hawley, Chicago, Ill. Filed August 11, 1905, and October 22, 1906. The generator has two armature windings, one for supplying the light circuit and the other for charging the storage battery.

906,071. MEANS FOR RECORDING METER READINGS. Samuel C. Shaffner, Chicago, Ill. Filed January 7, 1908. A lens and shutter are arranged to admit light on a photographic film when a lever is depressed.

906,081. APPARATUS FOR THE PRODUCTION OF OZONE. Jan Steynis, New York, N. Y. Filed January 24, 1908. There are means for producing the expansion of liquefied gas within hollow electrodes for absorbing the total heat developed by the stream discharges.

906,100. INDICATOR. Edward J. Burke, New York, N. Y. Filed August 1, 1906. Combined with a number of jacks is a normally rotating shaft carrying an indicator normally connected to it and means for disconnecting this when the pointer is directed toward a particular jack.

906,102. ART OF PRODUCING PIGMENTS BY ELECTROLYSIS. Edwin D. Chaplin, Boston, Mass., assignor to International Lead Companies. Filed February 3, 1906. The process of producing white lead consists in electrolytically separating an electrolyte into a solvent of lead and an alkaline hydrate.

906,103. ART OF PRODUCING LEAD SALTS BY ELECTROLYSIS. Edwin D. Chaplin, Boston, Mass., assignor to International Lead Companies. Filed February 3, 1906. Consists in electrolytically forming from ore or bullion as an anode a solution containing soluble salts of lead.

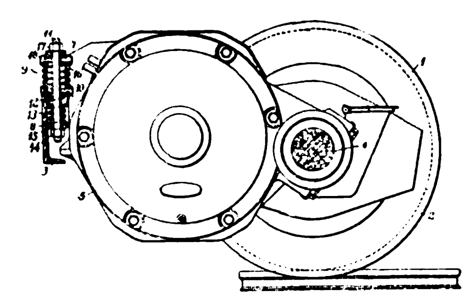
906,104. ELECTROLYTIC APPARATUS. Edwin D. Chaplin, Boston, Mass., assignor to International Lead Companies. Filed February 3, 1906. The apparatus used in the two preceding processes is described.

906,129. ELECTRIC APPARATUS FOR RAILWAY SWITCHES, SIGNALS AND THE LIKE. Lawrence Griffith, Yonkers, N. Y., assignor to Federal Signal Company. Filed April 8, 1903. This is a modification of No. 906,012.

906,160. MACHINE FOR CUTTING OUT MICA BETWEEN SEGMENTS IN COMMUTATORS. Otto F. Reinen, Los Angeles, Cal. Filed September 30, 1907. A cutter is mounted on a bracket so as to move reciprocally in a straight line.

906,161. TROLLEY DEVICE. Frank A. Robbins, Worcester, Mass. Filed November 11, 1907. The trolley harp extends normally at right angles to a trolley wire.

906,166. CAR SIGNAL. William H. Schweizer, Baltimore, Md. Filed October 8, 1907. Depression of a pedal on the platform closes the circuit of a signal over the other platform.



905,964.—ELECTRIC CAR MOTOR SUSPENSION.

906,172. PROCESS OF SMELTING ALUMINUM ORES. Frank J. Tone, Niagara Falls, N. Y., assignor to the Carborundum Company, Niagara Falls, N. Y. Filed September 14, 1907. Consists in making a mixture of aluminum silicate, carbon and a base metalliferous material and subjecting this to electrically-developed heat.

906,173. METHOD OF TREATING ALUMINUM SILICATE. Frank J. Tone, Niagara Falls, N. Y., assignor to the Carborundum Company, Niagara Falls, N. Y. Filed March 17, 1908. This is a modification of the above.

906,211. REGULATION OF THE PERIOD OR INDUCTANCE OF HIGH-FREQUENCY CIRCUITS. Gustave Ferrié, Paris, France. Filed May 8, 1907. The apparatus comprises an annular hollow conductor having a transverse gap, a conductor within this and means for regulating the resistance of the arrangement.

906,238. RAILWAY SIGNAL. Matthew M. Kane, Montgomery, Ala., assignor of one-half to William J. Gardner, Montgomery, Ala. Filed November 2, 1907. An electromagnet controls an armature lever which normally holds a set of signal wings in their "safe" position.

906,274. ELECTRIC INDICATOR. Carl von Peez, Vienna, Austria-Hungary. Filed October 4, 1907. A rotatable indication-carrier has a series of alternately and oppositely positioned teeth engaged by an armature lever under the control of an electromagnet.

906,279. TROLLEY CUT-OUT. Charles C. Phillips, Owensboro, Ky., assignor to the Phillips Automatic Signal Company, Owensboro, Ky. Filed May 9, 1907. A hanger has an arch-shaped member to the ends of which tiltable sections of the working conductor are pivoted.

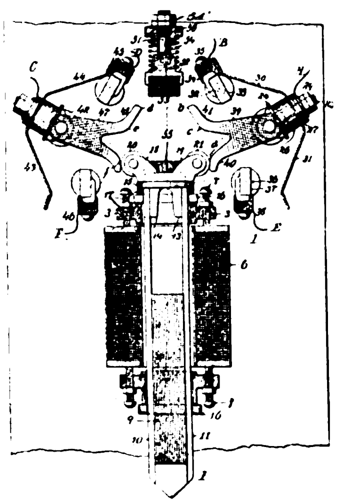
906,286. ELECTRIC-LIGHT-CORD TAKE-UP. Abraham W. Pratt, Eureka, Cal. Filed February 15, 1908. A supporting frame carries a spring-actuated reel.

906,290. SPARK-ADJUSTING STARTING MEANS FOR AUTOMOBILES. Andrew L. Riker, Short Hills, N. J., assignor to the Locomobile Company of America, New York, N. Y. Filed November 4, 1902. A governor changes the relative angular position of a rotary contact and brushes.

906,296. INSULATOR. Charles Rosenberg and Vernon T. Bailey, New York, N. Y. Filed March 18, 1908. A base of insulating material has posts at opposite sides and a socket centrally projecting from it.

906,317. ALTERNATING-CURRENT SWITCH. Frank W. Smith and Louis Larsen, New York, N. Y. Filed May 25, 1907. Combined with an electromagnet is an iron enclosing frame and a longitudinally movable core and means for maintaining equal air gas on the opposite sides of the core.

906,331. ELECTROMAGNETIC VALVE-OPERATING MECHANISM. Jacob B. Struble and Elmer R. Coe, Wilkinsburg, Pa., assignors to the Union Switch and Signal Company, Swissvale, Pa. Filed November 7, 1907. The electromagnet comprises a plunger actuated by a solenoid, a member extending through the plunger, links connected to the plunger and a yoke connected to the links and to this member.



906,317.—ALTERNATING-CURRENT SWITCH.

906,338. PROCESS OF PRODUCING SILICON. Frank J. Tone, Niagara Falls, N. Y., assignor to the Carborundum Company, Niagara Falls, N. Y. Filed September 14, 1907. A method of reducing aluminum silicate consists of forming a mixture of it and carbon and subjecting this to electrically-developed heat sufficient to reduce the silicon and to fuse the alumina.

906,357. THERMOSTAT. Alfred T. Ziegler, Allegheny, Pa. Filed September 24, 1907. There is an electrically-actuated valve in the gas-supply pipe, and electrical connections between the thermostat and the valve.

906,361. ELECTRIC SWITCH. Boyd W. Allen, Boston, Mass. Filed April 6, 1908. Comprises a rotative barrel provided with a number of teeth at different portions of its circumference, a guard and series of switches mounted thereon.

906,370. CONNECTOR FOR ELECTRICAL CONDUCTORS. Charles W. Beck, Rockville Center, N. Y. Filed March 12, 1908. Has two members pivotally connected together and provided with recesses to receive the binding post.

906,386. ROTARY SNAP-SWITCH. Charles A. Clark, Hartford, Conn., assignor to Trumbull Electric Manufacturing Company, Plainville, Conn. Filed October 24, 1907. A special construction is described.

906,405. MEANS FOR ELECTRICAL TRANSMISSION OF DESIGNS, FIGURES AND PHOTOGRAPHS. Guillermo J. de Guillén Garcia, Barcelona, Spain. Filed February 28, 1908. There are provided revolving transmitting and receiving cylinders, a plate of non-conductive material on the latter in contact with a brush in the circuit of the transmitting cylinder.

906,408. TOOL FOR ELECTRIC LAMP SOCKETS. Gilbert W. Goodridge, Bridgeport, Conn., assignor to the Bryant Electric Company, Bridgeport, Conn. Filed May 28, 1908. Has a handle and a circular head externally corrugated to fit within the corrugated flange of a socket cap.

906,411. GUARD FOR INCANDESCENT ELECTRIC LAMPS. William H. Greenwood, Everett, Mass. Filed November 7, 1907. A wire-work cage is secured to the socket by a divided cover, each part of which is pivoted to the top of the cage.

906,448. TERMINAL FOR ELECTRIC WIRES. Bernard Morgan, Newport, R. I. Filed February 6, 1908. A terminal tip is formed of sheet metal and has two wing portions adapted to grip the conductor and two spring clamp portions to engage a binding post.

906,468. PROCESS FOR THE PRODUCTION OF OZONE. Jan Steynis, New York, N. Y. Original application filed January 24, 1908. Divided and this application filed September 3, 1908. This is a modification of No. 906,081.

906,492. SAFETY DEVICE FOR RAILWAY SWITCH AND SIGNAL APPARATUS. Lawrence Griffith, Yonkers, N. Y., assignor to Federal Signal Company. Original application filed November 5, 1904. Divided and this application filed February 20, 1906. This is a modification of Nos. 906,012 and 906,192.

906,498. SHUNT OR ELECTRICAL RESISTANCE. Edward Weston, Newark, N. J. Filed March 15, 1907. A special form of ammeter shunt is described.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired December 15, 1908:

464,959. TELEPHONE. C. Cuttriss, New York, N. Y.

464,979. ELECTRIC SIGNALING APPARATUS. G. E. Miller, Lynn, Mass.

464,986. ELECTRIC CONDUCTOR. W. E. Cehrle, Philadelphia, Pa.

465,034. ELECTRIC CAR BRAKE. E. Verstraete, St. Louis, Mo.

465,078. METHOD OF CONTROLLING ALTERNATING-CURRENT INDUCTION. E. Thomson, Lynn, Mass.

465,089. RIVETING BY ELECTRICITY. E. E. Ries, Baltimore, Md.

465,104. DYNAMO-ELECTRIC MACHINE. W. P. Wiemann, Allegheny, Pa.

465,202. COUPLING FOR ELECTRIC CONDUCTORS. W. C. Preston, Providence, R. I.

465,206. PACKET OR PAD FOR ELECTRIC BATTERIES. L. H. Rogers, Brookline, Mass.

465,218. ADJUSTABLE RHEOSTAT. F. J. Sprague and C. R. Pratt, New York, N. Y.

465,233. COMMUTATOR CONNECTION FOR DYNAMO-ELECTRIC MACHINES. C. O. C. Billberg, Philadelphia, Pa.

465,234. BRUSH HOLDER FOR DYNAMO-ELECTRIC MACHINES OR MOTORS. C. O. C. Billberg, Philadelphia, Pa.

465,278. ELECTRICAL SEWER-GAS INDICATOR. J. J. Lawler, Scranton, Pa.

465,292. ELECTRIC MOTOR SWITCH. E. W. Rice, Jr., Lynn, Mass.

465,359. CONVERTER SYSTEM FOR ELECTRIC RAILWAYS. M. W. Dewey, Syracuse, N. Y.

465,360 and 465,361. ELECTRIC FAN. P. Diehl, Elizabeth, N. J.

465,365. BRACKET FOR SUPPORTING ELECTRIC CONDUCTORS. J. A. Duggan, Quincy, Mass.

465,369. PRODUCTION OF INSULATING COATINGS OR LININGS IN ELECTROLYTIC APPARATUS. L. Grabau, Hanover, Germany.

465,404. SWITCH-ACTUATING MECHANISM FOR ELECTRIC MOTORS. C. G. Armstrong, Chicago, Ill.

465,407. ELECTRIC RAILWAY. G. F. Green, Kalamazoo, Mich.

465,423. ELECTRIC HEATER. W. H. Boles, Syracuse, N. Y.

465,426. ELECTRIC SWITCH AND CASE FOR THE SAME. C. P. Chappell, Providence, R. I.

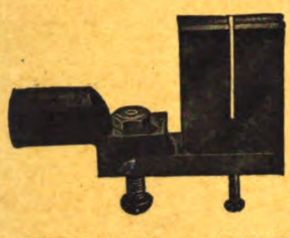
465,430. ELECTRIC CONNECTOR. W. F. Z. Desant, New York, N. Y.

465,432. ELECTRIC RAILWAY. G. F. Green, Kalamazoo, Mich.

ELECTRICAL REVIEW AND WESTERN ELECTRICIAN

VOL. LIII, No. 26. CHICAGO, SATURDAY, DECEMBER 26, 1908. THREE DOLLARS A YEAR Single Copies Ten Cents.

Enclosed Fuses and Slate Bases



Contacts of all SHAWMUT Fuse Bases above 60 amp. are made without use of castings. Drawn copper gives maximum conductivity.

CHASE-SHAWMUT COMPANY — **NEWBURYPORT, MASS.**

Keystone Portable Voltmeters for Direct-Current Circuits

The cut illustrated shows a portable voltmeter for direct current, with double scale, reading from 0 to 150, and from 0 to 15 volts.

All voltmeters are provided with a contact key, by means of which they may be readily cut into and out of circuit.

Our price list covers the ranges in common use; prices on special ranges or special combinations of ranges will be named on application.

No extra charge is made for voltmeters reading both right and left from zero, the list price of this class of voltmeters being the same as for the corresponding range of voltmeter, with zero at left of scale.

In double scale voltmeters the price is governed by the high range, and the low range will be varied to suit individual requirements without extra charge.

Catalogue 14 describes all our A. C. and D. C. Switchboard and portable instruments.

Alternating Current Regulation

This Company has not only designed but has in SUCCESSFUL OPERATION several alternating control storage battery plants. Contracts were taken under positive guarantees, which in every case have been fulfilled. The subject is not an EXPERIMENT with us and we can absolutely give you the results claimed. Our Engineering Department will gladly make investigations and submit reports.

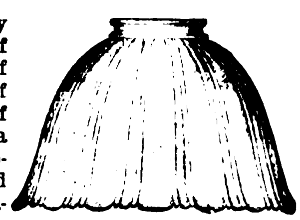
"OPALUX" GLASS REFLECTORS.

"OPALUX" TUNGSTEN FIXTURES.

Everybody using tungsten lamps is demanding artistic as well as efficient reflectors, and proper fixtures at reasonable cost.

In "Opalux" Glass Reflectors and "Opalux" Tungsten Fixtures this demand is met. "Opalux" Reflectors possess every essential requisite for perfect high-efficiency illumination.



Style S "Opalux" Reflector.

Its photometric curve, as tested by the Electric Testing Laboratories of New York, shows that its reflection of the light will give greater efficiency of illumination than any other form of glassware. In appearance it is such a beautiful blue white it has been pronounced a perfect blending of art and science. It represents mechanical stability; does not gather dust, presents a perfectly smooth patented surface inside and out, is easily cleaned, and can be sold within reasonable limits of cost. In fact it is a reflector that will quickly win the lead wherever it is seen.

A new and exclusive line of fixtures which are most practical for commercial use, and artistic as well, have also been developed for use with "Opalux" Reflectors, and, most important of all, they are durable and harmonize with all styles of decoration.

Send at once for our new booklet N, which fully describes and illustrates "Opalux" Reflectors and Fixtures, and gives complete prices of the various styles we can furnish.

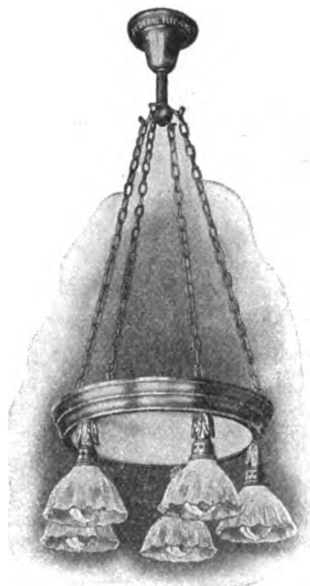
FEDERAL TUNGSTEN FIXTURES

For Brilliant Illumination

Federal Clusters are made for every purpose of illumination. Dozens of styles—marked not only by beauty of design but efficiency as well. Simplicity and durability are two very large characteristics of Federal construction.

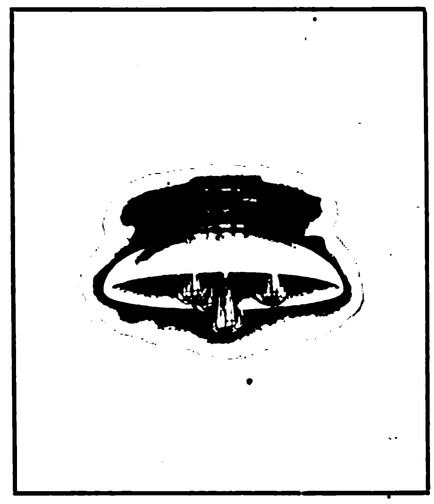
Federal Cluster No. 751

For brilliant illumination in halls, stores and offices. Available with units up to 100 watts and shades as large as the Holophane E 9 and I 9.



Federal Cluster No. 506.

For fine interiors, halls, stores, cafes, etc. Four sizes with diameters 15, 20, 25 and 30 inches. Available with from 3 to 10 lights. This cluster without chain or stem is especially effective for low ceilings.



Federal Cluster No. 771

For low ceilings. Has 15-inch brass canopy fitting close to ceiling, permitting Tungsten light to be used to best advantage in low rooms. Inexpensive—easily installed.

Federal Cluster No. 753

A Cluster which is both simple and artistic. Has a flat porcelain glass shade and Federal diffuser. Stem and fittings brass. For lamps not larger than 100 watt.

For information and prices on the many styles and sizes of Federal Clusters, write for Bulletin No. 987.

Federal Cluster No. 764

Chain Suspension Cluster with brass canopy. Is equipped with our specially-designed porcelain dome, shade and diffuser.

How many of your lighting customers are using a G. E. Coffee Percolator?

This percolator if used for only ten minutes, once a day, is equivalent to one lamp-hour (16 c. p.).

If you have 1,000 customers, each one using a G. E. Percolator ten minutes each morning, it means exactly the same to you as if they were using 1,000 16 c. p. lamps, burning from 7 to 8 A. M.

Each percolator placed on trial in a residence invariably means a sale. It increases your light load because it is used at least once a day, if not two or three times a day.

This new percolator is one of the best current-using household devices ever placed in the hands of Central Station Solicitors

1½ pints, 4 cups of coffee, 400 watts
3 pints, 8 cups of coffee, 500 watts
4 pints, 11 cups of coffee, 500 watts

Standard finish nickel
Special finishes to order

The Quick-Acting Pump

Sprays hot water on the coffee one minute after applying electric heat to cold water.

Handsome Appearance

The fine nickel finish harmonizes with other table furnishings and the percolator is not out of place in the most luxurious surroundings.

The Popular Price of this Percolator

Makes it appeal to all users of electric light.

CUTLER-HAMMER

PUSH-BUTTON PORCELAIN SPECIALTIES

The Switches with the Simple Three-Piece Mechanism.

Descriptive Booklet and Price List on Application

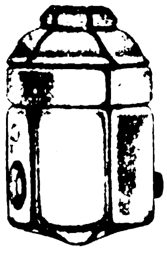
"Revolutionary in its nature."—*Electrical Review.*

"One of the most compact and ingeniously arranged circuit switches that has been produced."—*Electrical World.*

IT may be safely said that the mechanism of the new line of Cutler-Hammer Push-Button Specialties has evoked more enthusiastic commendations from the electrical trade than were ever before called forth by an improvement in switch mechanisms. It is, in fact, the first radical innovation that has been made in years. All other switches are more or less alike in principle and consist of from 30 to 40 separate parts, but here—at last—is something new in principle and so simple in construction that those who have examined it are inclined to believe not only that a great step in advance has been taken, but that the acme of simplicity in switch construction has been reached.

* * *

Imagine a switch mechanism that consists of only *three* moving parts—a mechanism that is snappy and positive in operation and absolutely new in principle. If you can't imagine it ask us to mail our "silent salesman"—a little working model of this new switch mechanism.

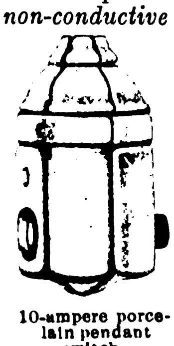


6-ampere porcelain pendant switch.

* * *

Bear in mind that in addition to the simple mechanism these switches and sockets possess a number of other advantages:

For one thing, they are made of porcelain—a *non-corrosive* and *non-conductive* material. This means that they will not tarnish like ordinary metal switches and sockets, nor is the user subjected to the risk of accidental shock while handling them, since all current-carrying parts are effectually insulated by the outer covering of porcelain.



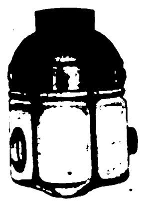
10-ampere porcelain pendant switch.

* * *

All of these devices are *self-indicating,* the position of the button showing whether the circuit is opened or closed.

Liberal space is provided for knotting the flexible cord and the removal of a single screw gives access to the interior of the switch, facilitating the wiring of these devices.

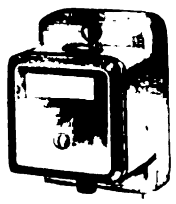
The fire glaze used on the porcelain is practically indestructible, while the choice of colors afforded is such that one can select a shade that will harmonize with almost any surroundings. The standard glazes are *Plain White, Ivory Tint, Wood Brown* and *Neutral Gray.* Special glazes can be furnished to order.



Brass cap pendant switch.

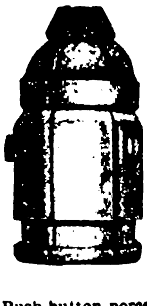
* * *

Two features of the molding switch are worthy of special mention. These switches are made *exactly the same width as standard molding* and are provided with caps designed to hold a small label. Their size makes it possible to install a number of these switches side by side without leaving space between the lines of molding, while their shape permits the capping to be cut off square instead of having to be whittled out to fit the switch, as in the case of round base switches. When assembled in gangs the label holder provides a place for a word or number indicating the circuit controlled by each switch. For use singly, molding and surface switches without label holders can be furnished.



Push-button molding switch with label holder.

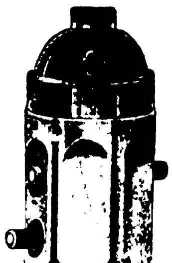
In the case of the lamp socket the substitution of the Push-Button Mechanism for the old-fashioned key commonly used results in a device that is not only more symmetrical in appearance, but which is admirably adapted for use with Tungsten or other lamps possessing a delicate, fragile filament, since the Push-Button Mechanism operates without tilting the lamp out of its normal vertical position or subjecting the filament to sudden jars. This socket has the same working parts as our 6-ampere switches, and therefore opens and closes the circuit with a much quicker and more positive snap than any other socket besides having a much larger current-carrying and breaking capacity.



Push-button porcelain pendant socket.

* * *

In conclusion, particular attention is called to the *two-circuit* pendant switch—the only switch of its kind on the market. A single one of these switches may be used to control two separate circuits in any of the standard clusters, or to control two separate groups of lights, or the switch may be so connected that one push-button controls the lights and the other button some other electrical device—such, for instance, as a fan. Many other applications of this two-circuit switch will readily occur to those familiar with electrical installations.



Two-circuit pendant switch. Porcelain body, brass cap.

* * *

Cutler-Hammer Push-Button Specialties can be secured from leading jobbers throughout the country. Descriptive Booklet and Price List mailed on application to the manufacturers.

CONTENTS.

CONTROL OF WATERPOWER.

A hydroelectric company often finds it of great advantage to control long stretches and many falls on the same river, and all of the power streams in the area served, for both technical and business reasons.

Where a number of waterpowers are developed at separate plants on the same river, each with more or less storage area behind it, the stored water in all of the ponds above a given plant can be made available there by a suitable division of the total load between all of these plants, if they are under a single control.

On a given river, the best reservoir sites are apt to be in long, deep valleys, or in lakes, near the headwaters, and unless at least a large part of the power of the stream is under a common control, it is hard to get effective co-operation for the construction of reservoirs that will benefit all alike, as some hope to obtain the benefit without the expense.

The areas covered by some of the large hydroelectric systems are so great that the power streams crossing them have their sources far apart, in different mountains or lakes, and thus present a variety of conditions, as to periods of maximum and minimum flow, and as to facilities for storage. By the control of waterpowers on several rivers that differ in such respects, it is often practicable to match the low discharge in one with a much higher discharge in another.

Another advantage in the common control of several power streams arises where one has large storage capacity, while there is little or no storage on the others. In a case of this sort, the stored water of one river may be held back for use in one or more dry months, while the other rivers generate most of the energy during the months of ample water. To realize the above advantages it is, of course, necessary that all of the hydroelectric stations be connected to the same transmission system, as is now the common practice.

Coming to the business reasons for a single control of all the large waterpowers that may be devoted to electrical supply in the service area of a hydroelectric system, it is well known that competition between such systems tends to produce rates that are much less than reasonable, and to the financial destruction of the weaker.

With government control of rates the reasons commonly given for competition no longer exist, and both the hydroelectric companies and the public will be benefited by such a combination of waterpowers as will yield the largest amount of service.

Many of the hydroelectric companies have not been slow to see the advantages to be derived from the control of all the waterpowers within their reach, on the same river and on different rivers. As a result, some of these companies own scores of miles of undeveloped rivers with hundreds and even thousands of feet of fall, besides enough developed waterpower to supply present needs.

Thus, one of the hydroelectric systems in Southern California, with seven developed waterpowers on four rivers, includes also about one hundred miles of the Kern River with a total fall of more than 4,000 feet and an estimated capacity of more than 77,000 horsepower. Northern California contains a hydroelectric system that includes no less than six waterpower plants with scores of miles and several thousand feet of fall along four rivers.

Waterpowers on the Hudson, Sacandagua and Schoharie rivers are united in one electric system, and have drainage areas more than one hundred miles apart, in the Catskill and the Adirondack mountains. One electric company owns water rights on the French Broad and Catawba rivers that are estimated to yield 150,000 horsepower, though less than one-half of this capacity has thus far been developed.

In Montana, the waterpowers along nearly fifty miles of the Missouri River, where the fall is 200 feet, have been developed for the three plants of a single electric system. A similar development is to be found on the Spokane River, which falls about 250 feet along the forty miles ending at Spokane, and this forty miles is controlled by an electric company that has thus far developed about one-half of this total fall. On the Muskegon River, the holdings of one electric company cover a sufficient length and fall for the development of nearly 75,000 horsepower.

Montreal is supplied with electric energy from four waterpower stations, two on the St. Lawrence, one on the Richelieu, and one on the St. Maurice River, and three of these stations are owned by the same company. Four hydroelectric plants on two rivers, all under a single ownership, develop electric energy for Manchester, N. H. Springfield, Mass., has electric service from two plants on one river, and Hartford, Conn., has like service from two plants on another. Buffalo is supplied with light and power from three hydroelectric plants at Niagara Falls, two in the United States and one in Canada, designed for an ultimate output of 215,000 electrical horsepower, which thus form the largest generating capacity in the world under a single management.

THE VALUE OF TESTING.

It is hardly realized by inventors and manufacturers who have not yet indulged in accurate and persistent testing of experimental apparatus the great degree to which saving in effort and expenditure could be extended by adopting the laboratory methods of larger organizations. It is safe to say that a large percentage of the new apparatus which has been placed on the market by small manufacturers has failed only because there has not been available the testing apparatus which would have indicated the weak point. A number of devices, excellent as a whole, have become discredited because, in the assembly, there was not available the means to determine that certain elements in the construction, although of apparent perfection when used individually, did not perform satisfactorily when used in connection with other devices.

It is not only with the inventor and manufacturer, however, that the necessary testing has been neglected. Large central stations and street railways have gone on buying without subjecting apparatus to tests other than those given by the manufacturer; and, although these are absolutely trustworthy and entirely cognizant of the guarantee which accompanies all first-class apparatus, they have not demonstrated a weakness which is often entailed due to the rigors of actual service.

The equipping of a laboratory sufficiently complete to undertake tests dealing with all the ramifications employed in actual service in electrical undertakings today would be far beyond the possibilities of all but the larger manufacturing companies, and also beyond the ordinary needs and requirements of most central-station and street-railway companies. It is true, however, and it is quite necessary, that a great deal of testing should be done by the companies themselves, and this can be carried on without very great expense on the part of these companies. Testing of an extraordinary nature, requiring apparatus which is seldom used and which can be secured only at great expense, can be done at the present time by commercial organizations which have been developed for this exclusive purpose. This service is not intended for, nor are these organizations ambitious to monopolize the testing of either the manufacturer or user of electrical apparatus. Where the parties requiring tests have no facilities whatever for testing, all their work can be properly and accurately attended to, but it would appear that the chief function of the testing organizations operated on a commercial scale is to supplement the testing which can ordinarily be carried out in fairly well-equipped laboratories with the tests which require special apparatus and which must be made frequently in order to return any profit on the investment necessary to secure it.

The value of testing on a commercial scale, although demonstrated to be great beyond the most sanguine expectations of its promoters, is not yet realized to the degree it will be when more extended use is made of the facilities of the commercial testing organizations.

THE INDEX TO VOL. LIII.

With this issue the index to Vol. LIII of the ELECTRICAL REVIEW AND WESTERN ELECTRICIAN is distributed to our readers. This index includes the issues of the *Electrical Review*, of New York, from July 4 to October 31, and of the ELECTRICAL REVIEW AND WESTERN ELECTRICIAN from November 7 to December 26. It will be remembered that the index to the issues of the *Western Electrician*, of Chicago, from July 4 to October 31, was distributed in the October 31 issue of that journal.

It is advisable that care be taken to preserve the index distributed this week, as it is not possible for the publisher to make a general distribution of extra copies.

DRAFTING IN THE SMALL CENTRAL STATION.

In a central station which is too small to afford a regular drafting organization, there is often a tendency to neglect the making and filing of proper drawings covering various changes and improvements in the system. The smaller number of officials and the greater variety of duties impressed upon individuals make it difficult to keep up with the work in the direction of accurate sketches of all noteworthy construction, and hence there is liable to come a time when new work is done more or less by rule of thumb. Without thorough planning, new engineering work is bound to cost more than it normally should, on account of the constant improvement in apparatus by the manufacturers, the alterations of dimensions in new types of equipment, and the necessity of making changes in temporary layouts.

It is therefore decidedly worth while to organize a small drafting department, even in the small station, and a company may well allow the superintendent or manager an extra man for this work. In most cases a corner of the office can be fitted up with the necessary drawing table and board, and the few simple instruments and supplies provided which will make it possible for neat and thorough work to be done within the limits of the requirements. In the smallest companies it is not unusual for the central-station manager to make his own sketches, when any are turned out, but experience shows the desirability of employing a draftsman for such work, with the all-important proviso that the new man be capable of doing other things besides drawing. There is no need of buying an elaborate drawing outfit, but provision for at least a small blue-print frame and the storage of drawings and prints, data, and special reports of a technical nature can be made with little trouble. Such a draftsman can have no better training for general central-station work than these odds and ends of technical and semi-commercial problems. He can be trained to work up operating results and statistics with the slide rule, to check up material and labor costs, accumulate data on power applications and new installations of high-efficiency lamps, and, in general, be a man of all-around usefulness. Work of this kind is excellent training for a young technical graduate, and it does not require expert ability in handling intricate designing problems. Much of the work can be done by drawing in machinery merely in outline, through the use of cardboard templates, tracing more complex equipment, if necessary, by using an incandescent lamp underneath a glass table of temporary character. The plan of numbering and indexing every sketch made is essential to the best results. For the use of the men in the field, a series of standard construction prints of a size that will fit the pocket well, is a great help, and will savé money through its effect in producing symmetrical installations. A given piece of work under a given set of conditions should cost about the same amount of money one time as another, and take about the same time for completion. Every central-station superintendent who administrates a small company can find plenty of work for a draftsman capable of being utilized on tests and investigations, technical records of routine operation, and, in some cases, soliciting. The main point is not so much the employment of another man in the small company for drafting alone, as the better attention to accurate records than now obtains in many cases, combined with a certain flexibility of the organization, which results when a man is available for special duties and not bound down all the time by purely routine work.

THE TELEPHONE AND CHRISTMAS SHOPPING.

The use of the telephone in making purchases is not confined to any particular locality or season, but that some of its possibilities remain to be developed is clearly indicated by the increased application of it this year in connection with the Christmas shopping of the larger cities. In New York in particular the retail stores encouraged holiday shopping by telephone, one house having placed twenty-five instruments on every floor and issued circulars to customers advising them to order in this way. The Boston *Transcript* well says that one of the great expenses in the conduct of the retail trade is the time-cost of the clerk, which stands against the average dollar's sale. The time required to effect a sale is often a long one in proportion to the results. The customer by telephone, like the mail-order customer, knows what he wants and is ready to ask for it. Delay is minimized.

The retail establishment receiving orders by either telephone or mail may accumulate them for systematic attention during the day, at hours when other demands are less pressing, this branch of the trade affording some balance-wheel against the irregularity in the flow of patronage through the doors. The telephone thus improves the load-factor of the establishment. For the thickly-settled districts the telephone occupies a valuable place between the mail order and the personal call; it lacks the recorded exactness of a written order through the post office, but it enables business to be expedited, facilitates the immediate distribution of information, and reduces congestion within the store and on the approaching streets and car lines. With the extension of the telephone habit, this aspect of electric communication is certain to grow to large proportions.

COPPER PRODUCTION IN 1907.

According to reports just issued by the United States Geological Survey, the output of copper, from the record production of 1906, shows a decrease of 48,809,191 pounds, or 5.3 per cent. The production in 1906 was 917,805,682 pounds, according to reports returned by the smelters of the country to the Survey. The smelter output chosen by the Survey as representative of the copper output of the country is made up of the production of blister copper and of furnace-refined, or so-called ingot copper of Michigan, plus the Michigan copper cast into ingots for electrolysis. It does not include the product of any additional distinctly refining process.

Based on reports collected by the field agents of the Survey from all mining companies in the country which produced copper during the year, the output was 847,151,015 pounds. This is 2.5 per cent less than the product of the smelters for the same period.

A Giant Chimney.

The largest and highest chimney in the world has just been completed at the smelting works of the Boston & Montana Consolidated Copper and Silver Mining Company, at Great Falls, Mont., for the dispersal at a great height of large volumes of gases from the copper smelters, says *The Engineering Record*. It is 506 feet high above its foundation, thus overtopping considerably all other chimneys. It rises 500 feet above the grade of the surrounding district and has an internal diameter at the top of fifty feet; it has been designed to remove 4,000,000 cubic feet of gases per minute at an average temperature of 600 degrees F. Owing to the rigid requirement imposed for its construction, including unusual stability against wind pressures, ability to withstand the action of acids formed from the waste gases, and strength to carry sixty feet of additional height with but small increase of the maximum bearing pressure, both its design and construction involved features of unusual interest.

The specifications limited the maximum bearing pressure due to both static load and the wind pressure of a 125-mile gale to twenty-one tons per square foot at any section, and required the construction to be capable of resisting the acid action of the sulphur gases. This practically limited the design to a brick chimney with an acid-proof lining, and as it was specified further that it should be so designed that sixty feet of additional height can be added without raising the maximum bearing pressure above twenty-two tons per square foot, the radial brick construction with perforated blocks was selected as best adapted for securing the degree of stability required. The construction was intrusted to the Alphons Custodis Chimney Construction Company of New York city.

New York Metropolitan Traction Reorganization.

The joint committee headed by John W. Castles, which represents the several committees of security holders of the New York city Metropolitan traction system for the purpose of formulating a plan of reorganization, has retained G. E. Tripp and the firm of Stone & Webster to collect data upon which to formulate such a plan. It is the purpose of the committee, it is stated, to obtain the full information regarding the earning capacity of the several parts of the Metropolitan system with a view of determining along what lines the reorganization should be conducted.

After Lighting Companies.

The Public Service Commission of the First District, state of New York, directed its counsel on December 18 to bring suit for penalties and forfeitures against five light and power companies for failure to file reports asked for. The Commission asked for the reports for the last six months of 1907, and stipulated in the order that they should be filed by November 30 of this year.

The Ball Electric Illuminating Company, the East River Gas Company, the Equity Gas Company, the Long Acre Electric Light and Power Company, and the Richmond Light and Railroad Company failed to obey the order. The penalty for disobedience under the law is a fine of not more than $5,000 a day. The Commission recently ordered similar suits brought against several of the traction companies for a similar failure to obey an order.

The Commission also adopted an order giving the Long Island Railroad ten days in which to reply to the complaint of M. H. Fishburn, who alleged that the company is charging excess fare on its line between Jamaica and the Flatbush Station. The complainant asserts that the ticket office is not open when he takes the train at Morris Park for Flatbush, and that the train conductor collects twenty cents, giving him a rebate check for ten cents.

The Chicago Electric Club.

The Chicago Electric Club has been holding a series of very successful midday luncheon meetings at its headquarters in the Chicago Automobile Club. On December 9, Peter Junkersfeld, of the Commonwealth Edison Company, delivered an address on "Recent Developments in the Edison Plant." On December 16, Philip Fisher, sales manager of the Condit Electrical Manufacturing Company, spoke on "Entertainment as a Feature in Securing Business." On December 23, the subject for the address was "Unfair Competition," by Luther L. Miller, member of the Chicago Bar. On December 30, the address will be delivered by Paul P. Bird, chief smoke inspector for the city of Chicago, on "The Problems Involved in the Smoke Inspection Service."

Columbia University Engineering Society.

At the December meeting of the Electrical Engineering Society of Columbia University held in New York city on December 16, C. F. Scott, of the Westinghouse Electric and Manufacturing Company, lectured on "Power Transmission." The speaker presented the limitations found in the development of various apparatus employed in the transmission of electric power and called attention to the fact that at one time the weak link of the chain lay in the generator, later in the switchboard, and again in the matter of insulation.

Car for Testing Rail Bonds.

A test car for locating faulty rail bonds which is now being used in Vienna, is described by *The Electrician*, London. The equipment consists of a direct-current motor-generator, which transforms the trolley voltage of 500 volts down to five volts, the full-load current at this voltage being 200 to 300 amperes. The poles of the machine are connected, through the axles, which are insulated from each other, to two points on the rail about seven feet apart. The voltage drop on a rail length of three feet is then measured by special contact.

High-Pressure Fire System for Chicago.

Milton J. Foreman, chairman of the Chicago City Council committee on local transportation, announces that plans for a high-pressure fire service, modeled after New York city's system of high-pressure mains, supplied by motor-driven centrifugal pumps, are being rapidly matured. The citizens' joint committee, Thomas R. Hall, chairman, and William Marshall Ellis, secretary, approves Mayor Busse's position that the cost of installation of high-pressure mains be met by special assessment of beneficiaries, and also that the system be installed without waiting for subway construction.

Operation of the Gary Steel Works Begun.

On December 21 active operation of the great steel works at Gary, Ind., was begun by starting the fire in blast furnace No. 12. These works have been building for several years, and when fully completed are to give employment to an aggregate of 25,000 to 30,000 men. Aside from the great size of the plant, it is noted for the very advanced methods to be employed in all departments of steel making, prominent among which is the most extensive use of electrical drive of heavy machinery that has ever been made in the iron and steel industry. Illustrated descriptions of the equipment of the works appeared in the ELECTRICAL REVIEW of October 17 and the WESTERN ELECTRICIAN of October 3, 1908.

Dr. Steinmetz Lectures on "Light and Illumination."

An audience of nearly 500 assembled in Fullerton Hall, Art Institute, Chicago, on the evening of December 17, to listen to an address by Dr. Charles P. Steinmetz. The meeting was held under the auspices of the Chicago Section of the American Institute of Electrical Engineers. President Louis A. Ferguson introduced the speaker, who lectured on "Light and Illumination." Although the address was on the same subject as that made by Dr. Steinmetz in New York a week earlier, which was reported in the ELECTRICAL REVIEW AND WESTERN ELECTRICIAN of last week, a great many features were dwelt on which had not been brought out in the earlier lecture.

The first part of the address was devoted to a discussion of the development and properties of illuminants, particularly the various types of electric lamps. In the second part, consideration was given to the physiological requirements necessary for good illumination. Throughout the problems of producing and utilizing artificial light effectively were looked at from the speaker's characteristic broad point of view.

Throughout the history of illuminants light has always been produced through the agency of heat. It is becoming generally understood that efficiency of light production increases with increase of temperature. The efficiency is still very low, as at best about ninety per cent of the energy is converted into heat. In electric lamps we can produce light either by sending current through the conductor, as in incandescent lamps, or by forming an arc, i. e., where vapor is the conductor. The latter is the earlier method, although the former seems simpler. The arc lamps were devised over a century ago.

Dr. Steinmetz then traced the general history of incandescent lamps. Carbon is a most refractory substance and stands the highest temperature; therefore it seems best adapted for filaments. The trouble with carbon, however, is that it vaporizes, like all substances more or less, at much below its boiling point. The condensation of the carbon on the inside of the globe (blackening) limits its value. Hence, it can be run up to a temperature of but 1,500 degrees C., or about 2,000 below the boiling point.

Different substances possess the evaporative power in different degrees, as, for instance, water and gasolene, the latter having a much higher vapor tension. So carbon has a relatively high vapor tension, and, therefore, we have now returned to metal filaments. Osmium produces filaments with an efficiency of about one-and-one-half watts per candlepower, but this metal is so rare that its demand for this purpose shortly doubled its price. Tantalum was then tried with fairly good results, and it is quite a common metal, whose vapor tension is small. Likewise with tungsten, the demand has stimulated the supply. Up to nearly its melting point, which is from 2,500 to 3,000 degrees C., its vapor tension is quite low. Once in a while a tungsten lamp blackens; this is due to imperfect vacuum.

Reverting to the improvement of carbon filaments, it should be noted that the bamboo filaments that were first made have a very high vapor tension. The squirted filaments are better in this respect and that which, after being formed, is subjected to gasolene vapor and has a coating of carbon deposited on it has a still lower vapor tension. The so-called metallized filaments are graphitized and have properties of metals to some extent. Another allotropic form of carbon may be found which will run its efficiency up to, or above that, of tungsten. The tungsten lamps have now a higher efficiency than arc lamps, except arcs of high power. The latter have their possibilities for high-intensity illumination.

In the development of the flaming arc there has been produced an illuminant independent of temperature for its efficiency. The frequency of vibrations of different vapors produces various wave-lengths, and therefore, various colors, if these lie within the visible range. The temperature of the vapor changes the color, due to affecting the various wave-lengths differently. For instance, in the mercury arc, as ordinarily used, the predominant vibration produces a bluish-green effect; if the vapor is hotter, the red rays overbalance this and produce a nearly white color; if the vapor is still hotter, a pinkish-red becomes prominent. The metals whose vapors are highly luminescent are mercury, used in the mercury-vapor arc, calcium, used in the flaming arc, and titanium, used in the magnetite arc.

Our hope for higher efficiency in electric illuminants lies, on the one hand, in finding other luminescent bodies or in improving those named, and, on the other hand, it lies in improving the carbon filament, so that we can use it to nearer its boiling point without vaporization, probably in another allotropic form.

However, we want not merely light but rather illumination. The first is the raw material; what we need is the flux of light properly distributed. In some places we desire uniform illumination, as in schoolrooms and on streets; again, we may want concentrated illumination, as on working surfaces for sewing or reading, or mixed illumination with low intensity for general lighting and higher intensity for the special field of vision. The important thing is not the amount of light falling on the illuminated object, but the effective physiological result.

Dr. Steinmetz dwelt at length on the requirements of the eye for good vision. For high brilliancy the eye adapts itself when the pupil contracts to reduce the amount of light admitted, especially if in the direct line of vision. This has led to the development of indirect illumination, to raising direct lights out of the line of sight and to reducing the intrinsic brilliancy. The fatigue of the eye is an important factor to be considered. Excessive illumination is always tiresome. Therefore, we should cut out the excess light. However, high intensity is not necessarily injurious, since the eye is accustomed to the great brightness of daylight, which is hundreds of times that produced by our ordinary illuminants. It will be found that a combined local concentrated and a low general illumination is the best, as it gives a quiet, homelike effect.

The sensitiveness of the eye varies for different colors at different intensities. The white arc is good for low intensity lighting. The flaming arc is not adapted for this, but is good for high intensities where striking effects are wanted. Yellowish light tones down differences in color. Blue or green light makes them more marked. Differences in color and brightness really afford effective means of vision. Shadows are necessary for perfect vision. Diffused or uniform illumination is consequently flat and unsatisfactory. The open arc lamp is the opposite extreme; its shadows are too sharp and intense. In some cases directed lighting is more necessary. In others, diffused lighting. Every case requires a most careful balance between the two types. The proper illumination is, therefore, much more difficult than that of the mere physical production of light flux. Photometric results are misleading, as they give no indication of the physiological stimulation that will be produced in the eye.

Copper Production in 1907.

The production of copper in the United States in 1907, according to reports returned by the smelters of the country to the United States Geological Survey, amounted to 868,996,491 pounds. The production in 1906, compiled on the same basis, was 917,805,682 pounds, and that of 1905 was 888,784,267 pounds. From the record production of 1906 the output for 1907 shows a decrease of 48,809,191 pounds, or 5.3 per cent. This is the largest actual decrease ever recorded, and is the largest relative decrease since 1886, when the percentage of decrease was 5.5. In 1907, for the first time since 1901, the production was smaller than that of the preceding year, and for the first time since 1872 the production was smaller than for the second preceding year.

The smelter output chosen by the Survey as representative of the copper output of the country is made up of the production of blister copper and of furnace-refined or so-called "ingot copper" of Michigan plus the Michigan copper cast into anodes for electrolysis. It thus consists of the final product of the distinctly smelting operations, and does not include the product of any additional distinctly refining process. The figures of smelter production for 1907 are based on direct returns made confidentially to the Geological Survey by all but one of the known smelting companies that handled United States ores, concentrates, or mattes, in 1907.

The quantity of copper given as the output of the mines of the United States in 1907, based on reports collected by field agents of the Geological Survey from all mining companies in the country which produced copper during the year, was 847,151,015 pounds, a quantity 2.5 per cent less than the product of the smelters for the same period. By far the greater portion of the mines' output is treated directly in smelters owned by, or having some connection with, the mining companies, and this large part of the mine production is reported on practically the same basis as the smelter production. But many of the mine returns are based on the actual or estimated recovery from the ore shipped from the mines during the year, whereas the smelter returns indicate the quantity of copper actually turned out at the reduction works in that period. In a state like Montana, therefore, operation of the smelters at full capacity for a few days after the mines had begun to reduce shipments would account for a distinct excess in smelter output over that reported from the mines. This fact—that when curtailment of production had once been decided on, the mines were able to execute the plan more promptly than the smelters—is responsible for the greater part of the difference between mine and smelter production of copper in 1907. In 1906, when mine and smelter production were conducted at practically the same rate, returns from the two sources were in very close correspondence, the mine output being only 0.9 per cent less than the production of the smelters. A second cause of the difference in favor of the smelter figures is the fact that the smelters recover more copper than the mines are paid for. The difference on this account is smaller than that due to other causes, but it is especially important in states like Colorado, where the greater part of the production is from custom ores generally low in copper.

During 1907 copper was produced in twenty-one states and territories, the production of the principal ones being shown in the following table:

State or Territory.	Smelter Returns.		Mine Returns. Pounds.
	Percentage of Total.	Pounds.	
Arizona	29.55	256,778,437	254,879,489
Montana.....	25.81	224,263,789	220,108,792
Michigan...	25.22	219,131,503	217,767,232
Utah.........	7.64	66,418,370	64,256,884
California....	3.88	33,696,602	28,528,020
Tennessee	2.24	19,745,119	18,893,115

These data are abstracted from an advance chapter on the production of copper in 1907, prepared for the annual report of the Geological Survey on the "Mineral Resources of the United States, Calendar Year 1907."

Electrical Equipment of the Singer Tower.

At the 281st meeting of the New York Electrical Society, held in the Singer Building, December 16, Charles G. Armstrong, consulting engineer, addressed the members.

Tower buildings, similar to the Singer, were only made possible by new devices for vertical transportation, said the speaker. The latest device, that used in the Singer tower, is simply an adaptation of the manual hoist, which is the earliest passenger elevator on record. It was found in the convent of St. Catherine on Mt. Sinai, about the sixth century.

Men and material have for many years been hoisted out of mines thousands of feet deep, but the power was applied at the surface of the earth. The first building hoists, or lifts, had their power applied in the basement, because steam was the only available motive power. The introduction of electricity, however, enabled the use of the hoist referred to, which can be placed at the top and makes the system of vertical transportation applicable to any possible height of building.

Mr. Armstrong then described his plan for exterior lighting of the Singer Building, by means of thirty searchlights or projectors, each eighteen inches in diameter. The architectural details and the color scheme of the tower are brought out in an effective manner by this flood of light.

A large number of stereopticon slides were shown, illustrating details of the construction of the building from foundation to flagpole.

The members of the society were greatly interested in the examination of the mechanical plant established in the Singer Building. This is considered one of the most modern and effective for its purpose in the world.

There were over 400 members present, and, notwithstanding the liberal provision of souvenirs made by the Singer Manufacturing Company, many of the visitors had to go away unsupplied. The company, however, will be pleased to send one of these interesting mementoes of the occasion to any member, on application to the company's office, 149 Broadway.

Through the courtesy of the Singer company, the members were divided into parties of thirty, with a guide for each party, and a tour of inspection of the entire building was made. Especial attention was called to the engine room, the main switchboard, the special plant of motor-generators for low-voltage circuits (fifteen volts), the vacuum-cleaning plant, the elevator plant and controlling, dispatching and signaling apparatus, and the searchlight equipment for night illumination of the building. A beautiful view was obtained from the tower. The entire inspection tour occupied about two hours' time.

British Post Office Wireless.

The first Post Office wireless station in England was opened by Postmaster-General Buxton on December 11. It is situated at Bolthead, on the Devonshire coast, and is intended primarily for communication with ships at sea.

Mr. Buxton, in a speech at the opening, intimated that a series of similar offices would be scattered throughout the United Kingdom.

Traffic on the Hudson & Manhattan.

Traffic over the completed section of the Hudson & Manhattan Railroad Company's tunnels, from the Lackawanna station in Hoboken, to Sixth Avenue and Twenty-third Street, Manhattan, has shown a monthly increase of approximately 150,000. In other words, the increase in the average daily travel in November was about 5,000 over the daily average in October, and that month showed the same relative increase over September. While the company will not publish any official figures on actual traffic, says the *Wall Street Journal,* it is conservatively estimated that the company is at present handling passengers at the rate of 20,000,000 a year. Officials of the company estimate that about seventy per cent of the traffic between the Lackawanna terminals and Manhattan is carried through the tunnels.

This section has now been in operation for a period of almost nine months, and the results that have been secured have far exceeded the previous expectations and have caused hearty optimism toward the results that will be obtained when the whole system is completed and in operation. That it meets the demands and requirements of the travel is being demonstrated thoroughly by the workings of this section, and the management feels little doubt but that the system will become the most important mouthpiece in the transportation to and from Manhattan of the four systems, the Pennsylvania, the Erie, the Lackawanna and the New Jersey Central, with its affiliated systems, the Reading and the Baltimore & Ohio. In addition, the interurban travel between the points is expected to be heavy.

The lower tunnels between the Pennsylvania terminal at Montgomery Street, Jersey City, and the Hudson Terminal buildings at Church, Cortland and Fulton Streets, Manhattan, will be completed and in operation by July 1 next, and will really constitute the main avenue of the system's traffic. Work on these sections has been pushed steadily, and the tunnel to Cortland Street will probably be broken through by March 1 next, but the other tube entering under Fulton Street is not so far advanced. The cutting on these tunnels averages twelve feet per day.

The transverse section on the Jersey side connecting the Pennsylvania, the Erie and the Lackawanna terminals will also be completed and in operation by July 1 next, so that the complete circuit will be in operation by that date. Plans have now been made up for the extension from the Pennsylvania Station to the Communipaw Station of the New Jersey Central, which is also the New York terminal of the Reading and Baltimore & Ohio systems.

It is estimated by officials of the Hudson Companies that the recent sale of $5,000,000 six per cent gold notes by that company, in addition to other assets already in hand, will supply sufficient funds to cover the completion of the system, and that no further financing will be required. The Hudson Companies is the constructing factor of the tunnels, having financed and built them, taking in payment $50,000,000 of the four-and-one-half per cent convertible bonds, in addition to stock of the Hudson & Manhattan Railroad Company, which is the operating company. The latter company has outstanding $5,250,000 five per cent non-cumulative preferred and $40,000,000 common stock.

Electrical Preparations for the Alaska-Yukon-Pacific Exposition at Seattle.

After expending in lump sums $910,000 for new cars, $600,000 for new trackage and $275,000 for motor-generators, transformers, high-tension transmission lines, lighting circuits, etc., the Seattle (Wash.) Electric Company, which controls the local street-car and lighting systems, will doubtless make a record in handling the traffic and lighting of the forthcoming Alaska-Yukon-Pacific Exposition. The improvements, new lines, and new power facilities which the company is installing preparatory to the 1909 fair mark a new era in street-railway improvement in the Northwest, and at the close of the exposition Seattle will be equipped with the most efficient service in the history of the city. The present expenditures will leave the car system in excellent shape after the exposition, and will insure prompt and comfortable handling of the crowds at the fair.

Four lines will tap the exposition grounds, two of which are now operating, with one other just completed and work on the fourth begun. Each line is five or six miles in length, and all will be double-tracked, with loop terminals at the grounds. A handsome terminal building and power substation will be installed on the grounds. The company expects to be able to deliver passengers at the grounds at the rate of twelve or fifteen thousand persons an hour, should the occasion demand.

The additional power necessary for these lines, and for lighting the exposition, will be furnished by the great water-power plant at Electron, on the Puyallup River, and by the steam plant at Georgetown. Twenty miles of 13,000-volt transmission line connects this power with the substation on the grounds, where it will be stepped down to 2,300 volts. Two 1,000-kilowatt motor-generators will be located at this station, and two others at substations in the city. The power will be sufficient to handle cars as rapidly as they can be safely moved over the four lines.

A lump order of 140 cars, forty of which have already been delivered, is probably without precedent among western street-car systems. The cars are of the most modern type, and cost when set up at Seattle about $6,500 each. They are manufactured by the St. Louis Car Company, and each car has 150 horsepower in motors, and is capable of developing a speed of thirty miles an hour. Stone & Webster, who control the company, are making the present improvements of the car system in the nature of permanent investments. For the lighting of the exposition the same company has the contract, and is preparing a most elaborate illumination. The substation on the grounds will contain four 1,000-kilowatt transformers, with the necessary regulators and switches. The water front on Lake Washington and the terraced hillsides overlooking the lake, with the wide avenues of the exposition leading down to the shore, will be brightly lighted, and the night scene from the water promises to be effective and inspiring.

American Society of Mechanical Engineers' Meeting.

The next monthly meeting of the American Society of Mechanical Engineers will be held in the Engineering Societies Building, on Tuesday evening, January 12. The paper, by Carl G. Barth, of Philadelphia, upon "The Transmission of Power by Leather Belting," will be illustrated by lantern slides. It will be a comprehensive summing up of the theory and practice of belting, in which conclusions are drawn from the work of Lewis, Bancroft, Bird and others, who have made experiments upon the transmission of power by belting. Valuable charts have been prepared by the author for the solution of belting problems.

Mr. Barth's data have been applied to belting in different plants for many years, giving an unusual opportunity to study the problem in great detail.

ALTERNATING CURRENTS AND THEIR APPLICATIONS.

BY EDSON R. WOLCOTT.

CHAPTER II. (PART III.)—OPERATION OF ALTERNATORS.

In the care and operation of generators certain precautions are very essential to high efficiency. It may not be out of place to incorporate here some suggestions from an instruction book issued by one of the large manufacturers of electric machinery.*

GENERAL CONSIDERATIONS.

1. Leave all switches open when the generator is not running.

2. Keep the generator clean and free from dust. With high-voltage machines a small accumulation of dust on the windings may be the cause of a serious burnout. It is advisable to use compressed air to clean the windings.

3. Small pieces of iron, such as bolts and tools, should be kept away from the generator.

4. Occasionally give the machine a thorough inspection; the higher the voltage, the more often this should be done.

5. Never run a composite-wound alternator with load unless all its brushes are in place, as an unduly high electromotive force will be generated in the open-circuited composite winding, which may puncture the insulation.

COLLECTOR RINGS AND COMMUTATOR.

Precaution should be taken to keep the collector rings clean, smooth and true. To prevent cutting, a little vaseline should be applied occasionally. The commutators of composite-wound generators should be kept smooth by the occasional use of No. 00 sandpaper. The lubricant should be applied to high-voltage generators with a piece of cloth attached to the end of a dry stick. If the commutator gets "out of true" it should be turned down. In the case of revolving-armature generators this can be done without removing the rotating part from its bearings, by the use of a special slide rest and by running the engine slowly, or the commutator may be taken off the shaft and turned down in a lathe.

BRUSHES.

Carbon or soft graphite brushes are preferable and are set perpendicular to the surface of the collecting rings. They fit closely and require almost no attention beyond an occasional renewal and casual inspection from time to time to see that they fit properly.

The copper brushes used to collect the direct current from the commutator of an alternating-current generator with a compensating winding, are arranged as shown in Fig. 57, which shows the correct method of setting the brushes on a commutator with ten segments. On different machines the brushes are set one, three or five segments apart; the operation of the commutator will be the same electrically as long as the brushes are an odd number of segments apart. The brushes nearest the field in one holder should be given a lead of about one-half a commutator segment (S/2) over its companion, while in the other holder the brush at the greatest distance from the field should have an equal load over the other brushes of its set. In the diagram, Fig. 57, the leading brushes touch the commutator at the middle segment, while the trailing brushes are just over the insulation between the segments. The

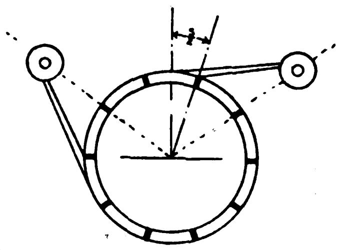

FIG. 57.—POSITION OF BRUSHES FOR COLLECTING DIRECT CURRENT FROM COMMUTATOR OF ALTERNATING-CURRENT GENERATOR.

trailing brushes should be set in position while the commutator is at rest, but the leading brushes may be changed while the machine is in operation. The compounding of a generator may be varied by shifting the brush-holder rocker, and, to a slight extent, by changing the spread of the brushes in each holder. Increasing the spread decreases the compounding, and vice versa. When the rocker arm is shifted to give the proper compounding, all brushes may be made to run sparkless by changing their spread. With a widely-varying inductive load, it is impossible to adjust composite brushes so as to obtain absolutely sparkless operation.

Sparking at the commutator may be due to any of the following causes:

1. Brushes may not be set at the point of commutation. A position can always be found where there is no appreciable sparking, and at this point the brushes should be secured.

2. Brushes may be loose or may not bear sufficiently on the commutator.

3. Brushes may be welded at the end.

4. Brushes may be spread at the end. They should present a narrow surface to the commutator.

5. Commutator may be dirty or oily, or copper dust may have collected on the insulating segments.

6. Commutator may be rough; if so, it should be smoothed off.

7. Generator may be overloaded.

BEARINGS.

The bearings should be kept clean and free from grit. They should be frequently examined to see that the oil supply is properly maintained.

A warm bearing or "hot box" may be due to any of the following causes:

1. Excessive belt tension.
2. Failure of the oil rings to revolve.
3. Rough bearing surface.
4. Improper fitting of the journal boxes.
5. Bent shaft.
6. Use of poor-grade or dirty oil.
7. End thrust, due to magnetic pull, the rotating part being "sucked" into the field because it extends beyond the field poles further at one end than at the other.
8. Bolts in the bearing cap may be too tight.
9. End thrust, due to improper leveling. A bearing may become warm because of excessive pressure exerted by the shoulder of the shaft against the side of the bearing.
10. Excessive side pull, because the rotating part is out of center.

OPENING OF FEEDER CIRCUITS.

If a line fuse blows, or a circuit-breaker opens, first open the switch corresponding to that line and then replace the fuse, or close the breaker; then close the switch. If the circuit opens again, examine the line for a short-circuit.

STARTING.

1. Examine the generator to see that it is in condition and is properly oiled.

2. Start slowly. See that the oil-rings are revolving properly.

3. Bring the machine up to speed, and turn the rheostat so that all the resistance is in the field circuit; then close the field switch.

4. Adjust the rheostat of the exciter for the normal exciting voltage; then gradually raise the alternator to its proper voltage by cutting out the resistance of its field rheostat.

5. Throw on the load.

*Westinghouse Electric and Manufacturing Company.

If the generator has a compensating winding, the brushes on the commutator must next be set at the non-sparking position. Should the current in the self-excited field cause a decrease in the voltage of the machine, it is evident that the separate and self-excited coils are opposing each other. The brushes should then be racked one segment forward or backward to reverse the current in the self-excited field.

CAUSES OF INSUFFICIENT VOLTAGE.

The following causes may prevent alternators from developing their normal electromotive force:

1. The speed of the generator may be below normal.

2. The switchboard instruments may be incorrect.

3. The voltage of the exciter may be low, because its speed is below normal, or its series field is reversed, or part of its shunt field is reversed or short-circuited.

4. The brushes of the exciter may be incorrectly set.

5. A part of the field rheostat or other unnecessary resistance may be in the field circuit.

STATIC SPARKS FROM BELTS.

In dry weather the charges of static electricity that accumulate on the belts may be of high enough potential to discharge to ground, or, if the generator is not grounded, these charges may jump to the armature or field winding and thence to ground, puncturing the insulation. By grounding the frame of the machine there is no danger to insulation.

TO SHUT DOWN.

1. Reduce the field current by means of the field rheostat.

2. Throw off the load by opening the feeder switches.

3. Open the separately excited field circuit.

4. Shut down the driving machine.

5. Clean the generator and put it in condition for the next start.

Canadian Centennial Exposition in 1912.

Western Canada is to hold a Centennial Exposition in 1912. Jefferson Clark, president of the Lewis and Clark Exposition, has been in Winnipeg, Manitoba, interesting business men in the project, upon the invitation of the Canadian Club of that city.

Electrical Trades Society of New York.

The thirteenth annual meeting of the Electrical Trades Society of New York was held at the Electrical Club, 14 Park Place, New York, on December 8. Ten accessions to membership during the year were reported. In his remarks the retiring president, R. B. Corey, after referring to the passing of the financial storm, said:

"Now what I want to bring out is the part played by this association in the saving of the day. Is there anyone who will say that there might not have been a score or more of failures had it not been for the co-operative spirit, part of which demonstrates itself in the existence of this organization? Can you not imagine the darkness and doubt which would have possessed the credit man were there no means of knowing what his fellows in the trade were doing? The most tangible indication of the soundness or weakness of customers, we maintain, is in the long run displayed to those who are close students of the association's bulletins, supplements and other records at the secretary's office. Congratulate yourselves, then, that you are members, and if you are not getting the most value for the least money and more than can be had from subscription to any mercantile agency, ask us why—addressing your inquiry to the secretary's office—and we'll soon tell you.

"At our meeting a year ago it seemed to be the consensus of opinion that customers who had always done fairly well in paying their bills and who were supposedly solvent should be given all necessary assistance in the way of leniency. In many cases our customers twelve months ago could not make collections from people who were ordinarily gilt-edged as to credit and payment. We all had to await the readjustment of credits and financial conditions, which readjustment came right along after the New Year. This leniency extended to creditors seems to have been general on the part of the electrical trade. The failures have been few in the territory of the New York Society, and, in fact, with the exception of some of the southern cities, the electrical trade has stood the strain very well indeed."

The secretary's report showed that out of claims aggregating $301,507 the society secured settlements amounting to $241,306, or eighty per cent. This is an average of $1,296 per member. The number of the separate accounts handled by the society was 2,939, of which 2,521 were settled through its instrumentality. This extra service is free, there being no charges or commissions, the annual dues covering everything.

The following directors were elected to serve for three years: John H. Dale, of the Dale Company; W. H. Roberts, of W. R. Ostrander & Co., and W. B. Wallace, of the Western Electric Company, who with the following will constitute the board of directors for 1909: W. M. Franksen, of the Sawyer-Man Company; G. F. Spencer, of I. P. Frink; A. L. Miller, of John A. Roebling's Sons' Company, and P. M. Haight, of the Sprague Electric Company. Mr. Dale was re-elected to the board of managers of the National Electrical Trades Association.

At a meeting of the directors, held immediately after this meeting of the society, the following officers were chosen for the next year: A. L. Miller, president; P. M. Haight, vice-president; W. H. Roberts, treasurer, and Franz Neilson, secretary.

Pennsylvania Railroad to Use Telephones in Dispatching.

It is understood from an official Pennsylvania Railroad source that in the near future the Pennsylvania will probably substitute telephones for the telegraph in dispatching trains and transacting other business that is now done by telegraph. The substitution, however, will depend entirely on the result of an investigation now being made of the efficiency of the telephone service on other railroads.

Several of the railroads now using the telephone system are reporting favorably on them, and say better and quicker service is obtained and is more economical. The New York division of the Pennsylvania has delegated a committee to investigate. This committee is now on a trip of investigation as far west as Chicago, where it is inquiring into the results attained by the use of telephones on the Chicago & Northwestern Railroad and other roads.

It was said that the Pennsylvania Railroad has already experimented with telephones on the line in Pennsylvania between Glen Loch and Morrisville, sixty miles, with satisfactory results.

Westinghouse Electric.

A certificate has been filed at Harrisburg of the proposed increase in the capital stock of the Westinghouse Electric and Manufacturing Company from $50,000,000 to $80,000,000, and permission to make the increase has been given.

HISTORY OF AXLE LIGHTING.[1]

BY W. L. BLISS.

(Concluded.)

The writer believes that one of the greatest contributions to the art of axle lighting was made by the inventor of the so-called outside suspension. This, as far as the writer is able to determine, was devised by Mr. Kennedy, in conjunction with certain officials of the Pennsylvania Lines West of Pittsburg. However. all of the axle-light companies have profited by the outside suspension, and certainly it has been a boon to the railroad electrician and inspector. The outside suspension made the generator accessible. It enabled a reasonably long belt to be employed, and it has probably come to stay. It was with a good deal of difficulty, however, that the mechanical officials of a great many roads were induced to sanction its application, on the grounds that it had a great many disadvantages, primary among which was that it unbalanced the truck. Theoretically, this is the fact, but practically it causes little, if any, unbalancing, especially on six-wheel trucks.

It would seem that the original method of driving the generator from the axle by means of a belt has prevailed, and that, up to the present time, all forms of gearing have been superseded and supplanted by the simpler form of belt. While the positiveness of direct gearing has its advantages and is absolutely indispensable in the case of street-railway motors, it is not so essential in axle lighting. In the case of a street-railway motor, if anything happens to the motor or to the gearing, the car is instantly brought to rest, and nothing further is done until the damage is repaired. If the mechanism is in such bad condition that it cannot be run rapidly, the car is hauled very slowly back to the repair shop. In the case of an axle generator, quite the reverse is true. If anything happens to the generator, the grinding -up process continues until nothing is left. If a hot bearing develops and the armature shaft binds, the belt forms a mechanical safety fuse between what may be regarded as an almost infinite power and a machine of decidedly finite endurance.

It would appear then, from developments up to date, that the most suitable form of mounting for an axle generator would be one which was, of course, simple and strong in its design, neat and shipshape in appearance, easily applied to the truck, and that, in its application, required no mutilation of the same. Such a mounting should permit the generator to be suspended outside and clear of the truck frame. The supporting bars of the suspension mechanism should be so disposed that the machine is completely accessible and that nothing shall stand in the way of the inspector who is examining or working upon the machine. The mounting and suspension should be such that the generator is at all times held level to prevent oil slopping, and it should be so designed that the shaft of the generator may be brought readily and accurately into parallelism with the axle of the car with a minimum amount of trouble. No better means of transmitting the power from the axle to the generator seems to have been brought forward than the rubber belt joined by means of the Crescent belt fastener. As above stated, the belt is a sort of mechanical safety fuse. Under ordinary weather conditions, it seems to be perfectly able to transmit the power. The great bugbear of snow and ice seems to have melted away before the light and warmth of experience. There are, no doubt, climates in which certain roads operate that are productive of considerable annoyance from snow and ice, but in most parts of the United States the rubber belt operating on large enough pulleys with wide enough faces and maintained at a proper tension by properly-designed tension devices, seems to fill the bill. It is cheap, safe and efficient. We have all heard more or less about driving by means of chains. The chain is necessarily more expensive than the belt. It in no wise has the great advantage of acting as a safety mechanical fuse, and it is a terrible thing when it gets loose and thrashes around. It is doubtful whether a chain can be run without lubrication, and the difficulty of enclosing it in a case that will hold oil is almost insurmountable, and who will bother to oil the individual iinks of a chain every few days? No one.

When it comes to machines of greater capacity than six to eight kilowatts, the rubber belt is probably inadequate as a driving mechanism. There is nothing left, apparently, but direct gearing. The writer designed, built and placed in operation a twenty-five-kilowatt axle generator on a truck of a locomotive tender. The axle was specially prepared. It was provided with a perfectly true gear seat and two polished journals, and the mounting of the machine was exactly like that employed in standard electric-railway service. Mechanically, this arrangement is perfect, or as near perfect as anything will ever be made. The gears were absolutely positive, were protected in a gear case of standard street-railway construction, and the whole machine, being large and heavy, permitted of rugged construction that withstood all the abuse and hammering that it received from the direct connection to the axle. Such a machine is perfectly suitable for head-end systems, but it cannot be operated under the ordinary conditions under which smaller axle machines are handled. So far as driving mechanisms are concerned, the outside suspension with the belt is the most suitable so far developed for small generators up to eight kilowatts capacity, and the standard street-railway mounting and drive, the only thing feasible for machines of larger capacity.

Having discussed the question of the problem of driving the axle generator, we come to the very important feature of taking care of the reversals in direction of car travel. This brings us immediately to the question of the pole changer. Pole changers can apparently be divided into the following classes: Mechanical and electrical. Under the head of mechanical pole changers we find two sub-classes, those having contacts and which momentarily break the circuit, and those which do not open the circuit, but which rely upon shifting the brushes to preserve the polarity. A mechanical pole changer is operated ordinarily from the shaft of the armature. When the armature shaft revolves in one direction the pole changer shifts certain connections so as to establish correct circuit relations corresponding to that direction of rotation, and vice versa. The brush-shifting devices depend upon rotating the brushes through as many degrees of arc as are represented by the pole pitch, plus whatever lead the designer desires to have the brushes take when commutating the current. The mechanical-switching pole changer, as distinguished from the mechanical brush-shifting pole changer, may be operated in any number of ways, all of which require considerable ingenuity to make substantial and efficient. Friction has been employed in a great many of them as the actuating force, but all friction schemes are open to the objection that a certain amount of wear goes on unless means are provided for relieving the friction, and attempts of this kind run into complication. The writer has himself preferred and developed the mechanical pole changer represented by the brush-shifting class.

[1]Abstract of a paper read before the Association of Car Lighting Engineers at the convention in Chicago on November 16.

There are a great many advantages in taking care of the polarity in this manner, and there are certain offsetting disadvantages no more numerous and no more important than the disadvantages that lie in the use of a mechanically-operated switch. There has not been a simple mechanical pole changer designed by anyone, as far as the writer is aware, and the shifting brushes and their associated mechanism are no more complicated than the simplest kind of mechanical pole changer, so that the question of mechanical pole changers cannot be said to have been settled by any standardizing, as is the case in the problem of mounting and driving.

When it comes to electrical pole changers, we find no end of schemes. The earliest American patent on an electrical pole changer appears to have been that taken out by Mr. Danals in 1889. His claim is very broad, but his device does not appear on the face of it operative. The most rational solution of an electrical pole changer, as far as the writer knows, is that offered in the patent of A. H. Whiting, in 1893. The objection to this is that it is necessary to separately excite the field of the generator in order to make the pole changer operative, and in the old Lewis system this was taken care of by a centrifugal switch, which closed and opened the field circuit of the generator directly from the batteries whenever the speed was above or below ten miles per hour, or thereabouts. The Whiting patent shows the essential elements of an electric pole changer, and while numerous variations have been made in the form of electric pole changers, they all depend upon Mr. Whiting's fundamental principle. Pole changers of the electric type necessarily are switching devices, and open and close the circuit.

There are, however, schemes by which the polarity of the generator may be preserved without the use of any switching mechanism or brush shifting whatever. They employ auxiliary machines for the purpose, and run into more or less complication and generally require the field of some machine somewhere in the system to be separately excited from the battery. We have also seen numerous attempts to solve the pole-changer problem by the use of alternators connected up with electrolytic cells and other rectifiers of one kind and another, and numerous other schemes have been proposed, but have not come into commercial use. The writer believes that the pole-changer problem will eventually be solved by the adoption of a mechanical pole changer of the shifting-brush type or a mechanical pole changer of the switching type, or an electrical pole changer of the Whiting type. It would seem that these three are the best forms to work upon and develop.

Coming now to the third part of the axle-light problem, we are confronted with the necessity of providing a means for closing and opening the generator circuit whenever the voltage of the generator shall be just above or just below that of the battery. In the early systems, a favorite means of accomplishing this result was through the instrumentality of a centrifugal switch, which would close and open the circuit at a predetermined speed of the generator. It is quite obvious that such an arrangemnt is impracticable. If the device is made thoroughly positive in its action, it will close and open the circuit mechanically without any regard to the electrical conditions that may exist in the system. In other words, it will connect a dead dynamo to a live battery or a live dynamo to a dead battery, either or both of which experiments have been repeatedly tried without success, so far as the writer is aware. There are certain experiments in railroading which, notwithstanding their fallacy has been thoroughly established, will continue to be made until the end of time. One of these experiments is the connecting of a dead generator to a live battery by those inquisitive people who want to see what will happen when the automatic switch closes, and generally find out. The other experiment is that of making two trains pass in opposite directions on a single track, which has probably been tried quite as many times as the former experiment without any successful records having been obtained. There is practically no prevention for the continuance of these experiments.

It would seem that the right way to operate an automatic switch is electrically. The switch should close at a predetermined voltage, no matter what the speed of the generator may be when this voltage is obtained. If the generator voltage at which the switch closes is equal, or approximately equal, to that of the battery at the time, no harm will result. The electrically-operated automatic switch, so far as the writer is able to ascertain, was first described by J. H. Holmes in a United States patent in 1891. He described accurately the switch that nearly all of the axle-light companies make today, consisting of some kind of magnetic circuit on which two coils or sets of coils act, one being made of fine wire and connected as a shunt to the generator and the other being made of coarse wire connected in series between the generator and the storage battery, as soon as the switch is closed.

Electricians all over the country, and, in fact, all over the world, are practically agreed upon the three problems the writer has endeavored to discuss. We all agree as to the requirements of the suspension and drive. We all agree that the polarity of the generator must be preserved, and that, whether circuit-changing or brush-shifting is employed, it must be accomplished before the speed reaches the critical or cutting-in value. And we are all agreed that the automatic switch, no matter of what form it may be or upon what principles it may act, must connect and disconnect the generator from the storage battery when the voltages bear the right relation. There are two more problems, however, connected with axle lighting upon which there is more diversity of opinion and a still greater diversity in means for accomplishment. The first is the question of regulating the generator; the second is that of maintaining constant lamp voltage.

The problem of regulating the generator depends upon the fundamental equation of the dynamo, which may be expressed as follows: $E = NCS$, where E is the electromotive force of the generator, N the number of lines of force supplied by the field and threading through the armature, C the number of conductors on the armature, and S the number of revolutions per second of the armature. In order to obtain a predetermined value for E, it is necessary that the product of NC and S be made equal to E. This gives us great and, in fact, unlimited latitude in the choice of our factors making up this expression. Confining ourselves to the axle-light problem and machines of from three to eight kilowatts capacity, the product of N and C is fixed by the size of the machine. The speed of the train at which it is desirable to have the generator become operative determines S. In ordinary axle-light work, S is generally made to correspond to between ten and twenty miles per hour, and the gear ratio between the axle pulley and that on the generator is generally made somewhere between two and three. S varies all the way from zero to some high value, and consequently E can vary from zero to a correspondingly high value. As S may be zero on account of the fact that the car must sometimes be at rest, E must sometimes be zero, and, therefore, if light is to be at all times available, a storage battery is absolutely indispensable.

This may seem elementary, but it is well to bear these facts in mind. In order to give E certain values it is necessary to manipulate the factors NC and S in some kind of automatic manner. In spite of everything that can be done, S will vary. Various schemes have been devised whereby S is allowed to vary from zero up to a certain value, and from that point on be held constant. Such schemes are elaborate and difficult to devise, and of necessity involve an automatic change in the gear ratio after a certain value of S has been obtained. C is a fixed quantity in a given machine, and it is very difficult to devise a means whereby it can be varied, although attempts have been made to do so. The easiest factor on the right-hand side of our fundamental equation to manipulate and vary is N, and this means that it is easier to vary the strength of the field of the generator automatically than it is to vary the number of conductors on the armature or control the speed of the same. There are no systems in commercial operation in which C and S are manipulated. N may be varied in but two ways. The magnetomotive force or ampere-turns of the field coil may be varied or the reluctance of the magnetic circuit may be varied. The latter is generally difficult to vary, as the form of the magnetic circuit in a given machine is generally permanent. Here again attempts have been made to vary the form and contour of the field and thus produce changes in the reluctance of the magnetic circuit, but all such schemes require complicated mechanical devices and have not come into general use.

The simplest and most direct method of varying the quantity N is by varying the magnetomotive force or ampere turns of the field. This may be done in an almost infinite variety of ways. Two general methods have been employed. As it is necessary to weaken the field of the generator as the speed increases above the critical value which has already been described, the most ordinary way of accomplishing this is to vary the current flowing through the field coil, or what is the same thing, vary the voltage impressed upon the field coil. The other method is to oppose the magnetomotive force of the original field coil by means of current flowing through a second coil acting differentially with the first. The latter method, known as the differential dynamo, requires no external regulator, but it has the serious disadvantage that it usually results in a great deal of heat being developed inside of the machine, and it requires additional coil space to accommodate the differential winding. These two disadvantages necessitate enlarging a machine for a given output and result in very greatly diminishing the efficiency of the machine as a generator. The differential method has the further disadvantage that it does not produce the regulation in the generator that is required and may be regarded as the crudest kind of regulation. The simplicity of the differential dynamo has attracted a good many inventors and designers, but there are no differential generators in use in axle lighting at the present time, so far as the writer is aware. The method of using an external regulator of some kind for properly varying the strength of the magnetic field of the generator has been adopted by practically all builders of axle-light machinery.

The writer will discard for purposes of present discussion all regulators that employ two sets of storage batteries or those types of regulators that fail to charge all of the cells of the battery uniformly or with the same current. This excludes the double-battery systems and the end-cell schemes of generator regulation.

External generator regulators which vary the strength of the current flowing through the field winding of the generator have been built with a view to accomplishing some particular end. There are regulators in which it is attempted to maintain the generator current constant at all times above operative speed. There are others in which it is attempted to maintain the current charging the battery constant under similar circumstances. There are regulators wherein it is attempted to maintain the generator voltage constant at all speeds above the critical. We may, therefore, divide regulators into three general classes, namely, constant total-current regulators, constant battery-current regulators and constant voltage regulators. Of these three general types of regulator, the constant total-current regulator is by far the easiest to build. There are no reversals of current to provide against and no great accuracy or refinement in regulation is necessary. As long as the current maintained by one of these regulators does not vary more than ten per cent and does not at any time exceed a certain maximum, the regulator may be considered perfect so far as it goes. The total-current regulator has the advantage that at all times the generator is working at practically its maximum capacity and efficiency. It has the great disadvantage, however, that unless fairly well adjusted to its run, batteries used in connection with this regulator will become overcharged and great deterioration of the same will result. Overcharged batteries, however, are probably somewhat in the minority, the honors in this respect having been pretty well carried off by the undercharged batteries. The ill effects of overcharged batteries do not make themselves apparent immediately and are really to be discovered in the expense account later on. Undercharged batteries, on the other hand, make their presence known as a rule by a failure in the light, which is the one great thing to guard against in axle lighting. Undercharging of batteries is probably not as destructive as overcharging, but even undercharging will result in greatly reduced capacity and probably permanent injury to the batteries through sulphation and other causes. The Kennedy, the Newbold, the Moskowitz and the Everett are types of constant total-current regulators.

Battery-current regulators are rather more difficult to construct than total-current regulators, as there is always a reversal of current in the controlling winding to be considered when the battery discharges. This, however, can be provided for by very simple means and need not necessarily be a handicap upon the regulator. The battery-current regulator has the advantage that the amount of charging that will be accomplished on a certain run may be predetermined as the charging current, whether it be constant or whether an average value only be considered, is never interfered with or influenced by the lamp load. As to how much the lamps on a given run will be used is an impossible matter to determine, but with the battery-current regulator the amount of charging and discharging can be pretty accurately predetermined and the regulator set to take care of the run very nicely. The battery-current system of regulation very seldom results in overcharging the battery, and, as above mentioned, may possibly result in undercharging. The battery-current system of regulation also permits of a ready means of lamp regulation without complicating the structure of the apparatus to any great extent. The writer here may be pardoned for referring to the bucker system developed by him, which is the only battery-current system about which he has any exact knowledge. In the bucker system the generator regulation is taken care of by a counter-electromotive force and without very much addition to the apparatus necessary for regulating the generator, a very good lamp regulator, and one almost theoretically perfect, may be added without much expense. The battery-current system of regulation, as exemplified in the bucker, employs the important principle that the varying charging current which takes place with varying speeds is a linear function of the excess-battery voltage required for charging the battery and by properly designing the apparatus a constant lamp voltage can be maintained independent of speed and lamp load, provided the battery remains within the limits of the straight-line portion of the charging curve.

Of course, it is quite possible with any type of regulator to devise some means whereby the charging process may be discontinued after the battery has become fully charged. Such devices, however, are unsatisfactory and have not to any great extent gone into general service. These devices are of necessity sensitive and complicated and their development is not likely to be prosecuted with very much vigor.

Constant-potential regulators for the generator have been and can be made. If constructed upon the voltmeter-relay principle they are, however, apt to be very unsatisfactory. The voltmeter relay is of necessity very delicate and uncertain in its action. Assuming, however, that a satisfactory and reliable voltage regulator for the generator can be obtained, it is somewhat of a question as to what voltage it should be set unless an independent lamp regulator is contemplated. If such a voltage regulator is set high enough to insure the batteries being fully charged, the voltage impressed upon the lamps will be altogether too high. A constant-potential regulator has the advantage that by its use storage batteries are pretty certain to become fully charged and never overcharged. It has the disadvantage, however, that if the batteries are in a very low or exhausted condition the generator is likely to become overloaded when it begins to charge such a set of batteries. It would seem then that the ideal generator regulator should combine the good features of the constant-current regulator and the constant-potential regulator.

It is absolutely essential that the generator voltage be equal to the battery voltage at the time the automatic switch closes, otherwise the fact that the automatic switch has closed will be too publicly advertised. It is also just as essential that the voltage of the generator shall rise high enough to force the full charging current through the storage battery with as little increase in speed above the critical speed as possible. This condition is necessary in order that the charging of the battery may begin to take place as early as possible and be continued as late as possible in order to take maximum advantage of the car's travel. The generator regulator should be so constructed that it will permit the generator to deliver its full current into the storage batteries, if no lights are turned on, at as low a speed as possible above the critical speed. To prevent overloading the generator, the regulator should be so constructed that this current will not be exceeded at any speed or on an exhausted battery or even on a dead short-circuit. As this maximum current is forced through the storage battery, its counter-electromotive force will rise and the voltage of the generator must rise also to continue to force the full maximum current through the storage battery. It is needless to state, the storage battery should be of such a size and capacity as to permit of this action. Just as soon, however, as the storage battery has become fully charged the current from the generator should begin to diminish and produce what is known as taper charge. If, however, while this process of charging is going on, lamps should be turned on, the generator should be able to furnish current immediately for these lamps so that no discharge from the battery shall be necessary, at the same time preserving the electrical conditions in the system so that no further charging of the battery shall take place if it has reached the point of being fully charged. Concisely stated, these conditions may be described as follows: A perfect generator regulator is one that tends to maintain the kilowatt output of the generator at a constant maximum without allowing either factor of the same to exceed a fixed maximum—that is to say, if a generator has a normal capacity of fifty amperes at eighty volts, which would be high enough voltage to charge thirty-two cells of battery connected in series, the regulator should permit the generator at all times to put out fifty amperes if there is anything legitimately entitled to receive this current and to limit the voltage of the generator to eighty volts. Such a regulator would, to the writer's mind, be perfect, and he is quite certain that such a regulator can be made and has been made and put into practical operation.

The means for immediately varying the strength of the current in the field of the generator may be a rheostat or a counter - electromotive force. Rheostats may be made in a variety of forms, but they should be so constructed that their steps are very fine or infinitely small, or else the passing from one step to another will be noticeable in the lamps. Rheostats for this purpose are generally constructed in one of three ways. They are either composed of definite steps or resistance brought out to contact plates or buttons over which a sliding contact passes, or they may be made of carbon disks subjected to varying pressures, or they may be made of the contacting type of which the regulator invented by S. W. Everett is a good example. A counter-electromotive force may also be employed, of which the bucker invented by the writer may be taken as a type. If any of these rheostats or counter-electromotive force devices can be controlled so as to produce the tendency toward maximum constant wattage without the factors of current and electromotive force, which make up this wattage, being allowed to exceed certain maximum values, they may be employed in the construction of an ideal regulator.

If a regulator is built along the lines and according to the requirements as set forth it will operate just as well in a one-car system as in a train-lighting system, and will, without readjustment, take care of any load within limits of capacity that is placed upon it, no matter what form that load may take. The load may be composed of the batteries and lamps on one car, or it may be composed of the batteries on one car and the lamps on a half-dozen other cars, or it may be composed of the lamps on one car and the batteries on another car, and still the regulator will, within the capacity of the generator, perform its functions in an ideal manner and the treatment that the batteries will receive will be in practical accordance with the most up-to-date ideas of storage-battery engineers. Such a regulator requires no readjustment to take care of varying schedules, changes of season or character of load.

The last problem to be considered in axle lighting is that of maintaining the lamp voltage constant. Here there is no room for any diversity of opinion. If a lamp can be found whose candlepower will not vary too widely with a range of twenty per cent variation in voltage and whose life and initial candlepower do not suffer by such variation, then the services of a lamp regulator may be consistently dispensed with. The carbon-filament lamp certainly does not fulfill these conditions. The tungsten lamp more nearly fulfills these conditions than any other lamp that has been devised, but no one will say that a tungsten lamp or any other kind of lamp is not brighter on two-and-one-half volts per cell than it is on two volts per cell. There are some engineers in this association who may be satisfied with the approximate lamp regulation which may be afforded by throwing into circuit fixed resistances, but the writer hardly considers devices of this kind regulators. They are more of the nature of protective devices. It has been a favorite scheme with a great many designers to use the motion of the automatic switch for throwing in such resistance to protect the lamps. It has also been common practice to utilize the initial motion of the rheostat controlling the generator for the same purpose. This, however, is not regulation. It affords a measure of protection to the lamps, but it does not reduce variations in lamp voltage.

To produce or construct a theoretically perfect lamp regulator is by no means an easy task. In the first place, such an instrument must be extremely sensitive and must respond definitely to very slight changes in voltage. Variations in the neighborhood of a half a volt should cause such an instrument to respond definitely and positively. It is almost impossible to make such a device operate directly a lamp regulator whose resistance is to take care of or dissipate twenty volts and thirty or forty amperes. Consequently a lamp regulator to be sensitive and positive is generally furnished with some kind of a relay device which possesses the required sensitiveness and which in turn actuates or controls the mechanism for varying the heavy resistance in the lamp circuit proper. The actual device for taking up the drop in the lamp circuit may be either a rheostat or a counter-electromotive force or an end-cell arrangement. For obvious reasons the last is to be avoided, as the unequal charging and discharging of the various cells in the battery only add another difficulty. The steps of a lamp rheostat should be infinitely small, which practically precludes the use of a rheostat made with definite steps of resistance. The carbon disc rheostat lends itself admirably to this purpose, although it is needless to state that it is open to some objections. A counter-electromotive force may be controlled so as to produce infinitesimal variations in voltage, but here again a certain amount of complication is almost indispensable.

An ideal lamp regulator must be able to maintain constant lamp voltage, while the generator and battery voltage vary from two to two-and-one-half volts per cell, and while the lamp current varies from, say, one-half to fifty amperes. If such a lamp regulator can be devised it can be used with equal advantage in an axle system applied to a single car, or it may be used to control the lamps where the current is furnished from a head-end generator, either of the steam or the axle-driven type, or even where the storage batteries have to be charged at a terminal and the lamps used at the same time, as is often necessary when cars are cleaned at night. The lamp regulator should be carried upon the car. It must be ready at all times to reduce the line voltage to normal lamp voltage. The lamp regulator must be separate and distinct from the generator regulator and the action of one must not depend or reflect upon the action of the other. When the lamp regulator is made thus and the generator regulator as above described, a flexible, universal, interchangeable car and train-lighting system will result.

In thus attempting to outline the history of the development of the various elements comprising an axle-light system and in discussing the problems which confront the engineer and designer in meeting the requirements of such a system, the writer has endeavored to eliminate the description of specific devices either of his own or of other inventors' designs.

Fort Wayne Section, American Institute of Electrical Engineers.

The Fort Wayne Section of the American Institute of Electrical Engineers held its regular monthly meeting December 16 at the Anthony Wayne Club, Fort Wayne, Ind. The meeting was preceded by a dinner served in the club dining room, at which most of the members of the Fort Wayne Section and quite a number of visitors were present.

The regular meeting of the section was addressed by E. A. Barnes, superintendent of the Fort Wayne Electric Works, on "Choice of Power for Manufacturing Industries." The paper dealt with the kinds of power which can be used for manufacturing industries, taking up successively power purchased from central stations, power from gas-producer engines, gas engines and fuel-oil engines, and waterpower. Finally the speaker discussed the relative merits of reciprocating and turbine engines, running condensing and non-condensing, and pointed out the advantages which he claimed for non-condensing engines, asserting that the heat which can be recovered from the exhaust steam makes a saving for the factory which more than counterbalances the saving in coal consumption which can be gained by using condensing engines. Mr. Barnes presented some very interesting figures supporting his claims in this regard. The paper was followed by a lively technical discussion by many of those present who are interested in this work.

At the January meeting L. D. Nordstrum will present a paper on "Some Considerations Involved in the Design of Direct-Current Generators and Motors."

ome Handsome and Serviceable Central-Station Advertising.

The Commonwealth Edison Company, Chicago, Ill., is keeping up its reputation for fine display and attractive service in its publicity department. Among the pieces of literature which are attracting particular attention just now is a return postal-card making a Christmas suggestion of the old-fashioned kind. This postal-card bears an illustration of a beautiful Vienna portable electrolier, and the same device used as a wall lamp.

Another holiday suggestion is entitled "An Electrical Christmas." This reproduces Clement C. Moore's beautiful poem, "The Night Before Christmas," and then, in fine half-tone illustrations, shows the many novelties which might bring happiness to every member of the family in the shape of an electrically-operated utility.

The "Handbook of Central-Station Electric-Light and Power Service" delivers a series of profitable essays on "How to Obtain Electric Service," "Rates for Electricity," "Reading of Meters," "Methods of Figuring Bills," "Lamps," "Heating and Cooking Appliances," "Repair Service," and "Shops."

The beautiful souvenir of the Fisk Street power house, with a handsome cream-colored cover, illuminated with gold-leaf, is one of the most attractive pieces of literature which has been issued by anyone in a long time.

The company's publicity service is under the direction of Dana H. Howard, manager of the advertising department, who is to be congratulated upon this excellent series.

Hawaiian Electrical Notes.

The Honolulu Rapid Transit and Land Company has announced that it will shortly make a number of extensions of its service to connect with the city the various forts and military posts which are being built by the navy and war departments. Surveys have been completed for a line six miles in length to connect with the new naval station at Pearl Harbor, and a branch will also be extended eastward from the city to reach the fortifications about completed at Diamond Head. Another branch will probably be extended into the military reservation at Waikiki Beach.

The territorial superintendent of public works, Marston Campbell, will ask the next Legislature, which meets in February, for appropriations to install a 12,000-horsepower electric plant at the Nuuanu Valley Dam, now nearing completion. The new reservoir will supply water with a 900-foot head, which the superintendent plans to use entirely for power, pumping the domestic supply for the city from artesian wells. The plans also contemplate utilizing as a reservoir the concave crater of Punchbowl Hill, back of the city, which has an elevation of about 400 feet. The electric plant is also designed to light Honolulu.

The Hawaiian Telegraph and Telephone Company is the new name of the wireless-telegraph company, as authorized by the Territorial Treasurer. The company has announced, through its president, C. J. Hutchins, the acquisition of the franchise of the Standard Telephone Company, and a contract with the Automatic Electric Company, of Chicago, for the installation of a new telephone system in Honolulu. The company at the present time operates the very efficient wireless-telegraph system between the islands of the group, and the big Kahuku station, which has established successful wireless communication with the mainland. The purchase of property by the company for exchange purposes was recorded recently, and the statement is given out that an up-to-date telephone central station will be built at once. The new telephone system will be of the automatic type, and the company will install a complete underground system for its wires. The project, it is understood, has been financed through the Metropolitan Trust and Savings Bank, of Los Angeles. The company is at the present time experimenting with wireless telephony between the islands.

Notes on the Electrical Engineering Courses at the "Boston Tech."

As is well known, the Massachusetts Institute of Technology maintains strong undergraduate courses in engineering, but it is not so well known that the Institute is attended by what is probably the largest number of graduate students in any of the engineering schools in the country. There are now 215 graduate students studying at the "Tech." The degrees of these men have been conferred by colleges and engineering schools through the continent.

A notably large number of the young men studying electrical engineering at the Institute come from among these graduate students. Many of these students in the electrical-engineering course have heretofore pursued a course in arts or in general science, and are spending two or three years in completing the electrical-engineering course at the Institute. Others have graduated from other engineering schools and are spending from one to two years in study at the Institute to get its baccalaureate degree in electrical engineering; and a few of particularly high preparation are pursuing advanced study and research for the purpose of obtaining the higher degrees of master of science in electrical engineering or doctor of engineering.

It is probable that the latter students occupied in advanced study and research are enjoying the first regularly organized work in this country leading to the degree of doctor of engineering. That degree has heretofore been conferred by American engineering schools as an honorary distinction, but it has not in this country been recognized among the degrees to be secured by study and research in the schools. Brilliant work has been done by students studying for this degree in the great polytechnic schools at Berlin and Carlsruhe, Germany, and work of this nature at the Massachusetts Institute of Technology bids fair to become popular with students of the highest ability and to be influential in the development of engineering research.

The undergraduate electrical engineering course at the Institute of Technology has a senior class, which is twenty per cent larger this year than last year, and the department will soon be a candidate for larger quarters. The laboratory quarters are large and are impressive in their equipment, but even they are becoming overcrowded, and additional classrooms are much needed. The prospects of entering into larger quarters are bright with the advent of the recently-elected president, Dr. Richard C. Maclaurin.

Brooklyn Edison Section, National Electric Light Association.

The first regular meeting of the Brooklyn Edison Company Section of the National Electric Light Association was held December 14, at the Edison Club rooms, Johnston Building, Brooklyn, N. Y. G. L. Knight, chairman of the Section, presided, and 140 members attended. Although the proceedings were not completed until nearly midnight, the enthusiasm and interest were maintained throughout. After an address of congratulation and encouragement by the chairman, Secretary E. A. Bailey read letters from President W. C. L. Eglin and Assistant Secretary Harriet S. Billings, of the National association, both of whom referred to the first number of the bulletin of the Brooklyn company's Section in terms of praise, President Eglin declaring that this publication set a standard and a pace that it would be difficult for other company sections to excel.

The bulletin, which was distributed to those present, contained, in addition to editorial and news matter of general interest to the members of the Section, the complete text and illustrations of all the papers presented on the occasion.

The first paper of the evening was on "Modern Power Plant Design," by F. W. Harrison and M. J. Shugrue. The paper was illustrated by lantern slides, and the subject was treated under the following headings: The building, coal, steam, electrical energy, switch-house, control board, switches, exciters and connections.

The next paper, entitled "Developments in Incandescent Lamps," was also written and delivered in two sections; the first section, viewing the subject from a manufacturing standpoint, by E. B. Rannells, and the second, on the reasons for higher efficiency, and the commercial bearing of the new developments, by M. S. Seelman, Jr.

The last paper of the evening, entitled "Some Notes on the Friction of Shafting," was written by C. A. Graves, and was a practical discussion embodying some interesting and useful data.

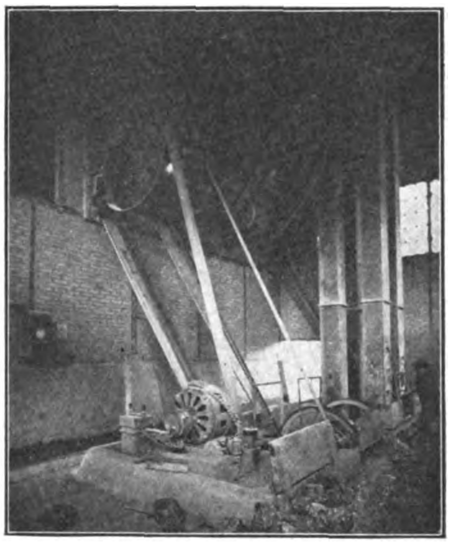
After the reading of the papers was completed, the members took up their discussion in a very spirited and general manner.

The next session will be held in February.

Electric Driving of a German Portland Cement Mill.

BY DR. ALFRED GRADENWITZ.

Portland cement, a combination of lime and slate-holding materials, when stirred with water is known to harden after a given time without any deformation, and is a most valuable material both for the making of mortar and the construction of foundations, etc. The methods of manufacturing Portland cement have been thoroughly modified since the introduction of mechanical operation. Whereas the raw materials formerly were crushed and mixed in stirring tanks in order then to shape the mud into bricks, which after drying were burned in the furnace into clinkers, mechanical operation has now been substituted for hand labor, not only in driving the crushers, crushing rolls, drying drums and grinding mills, but for all the transporting devices used in connection with cement manufacture. The number of hands required is thus reduced considerably and the troublesome production of dust is kept within very low limits by the installation of ventilating fans.

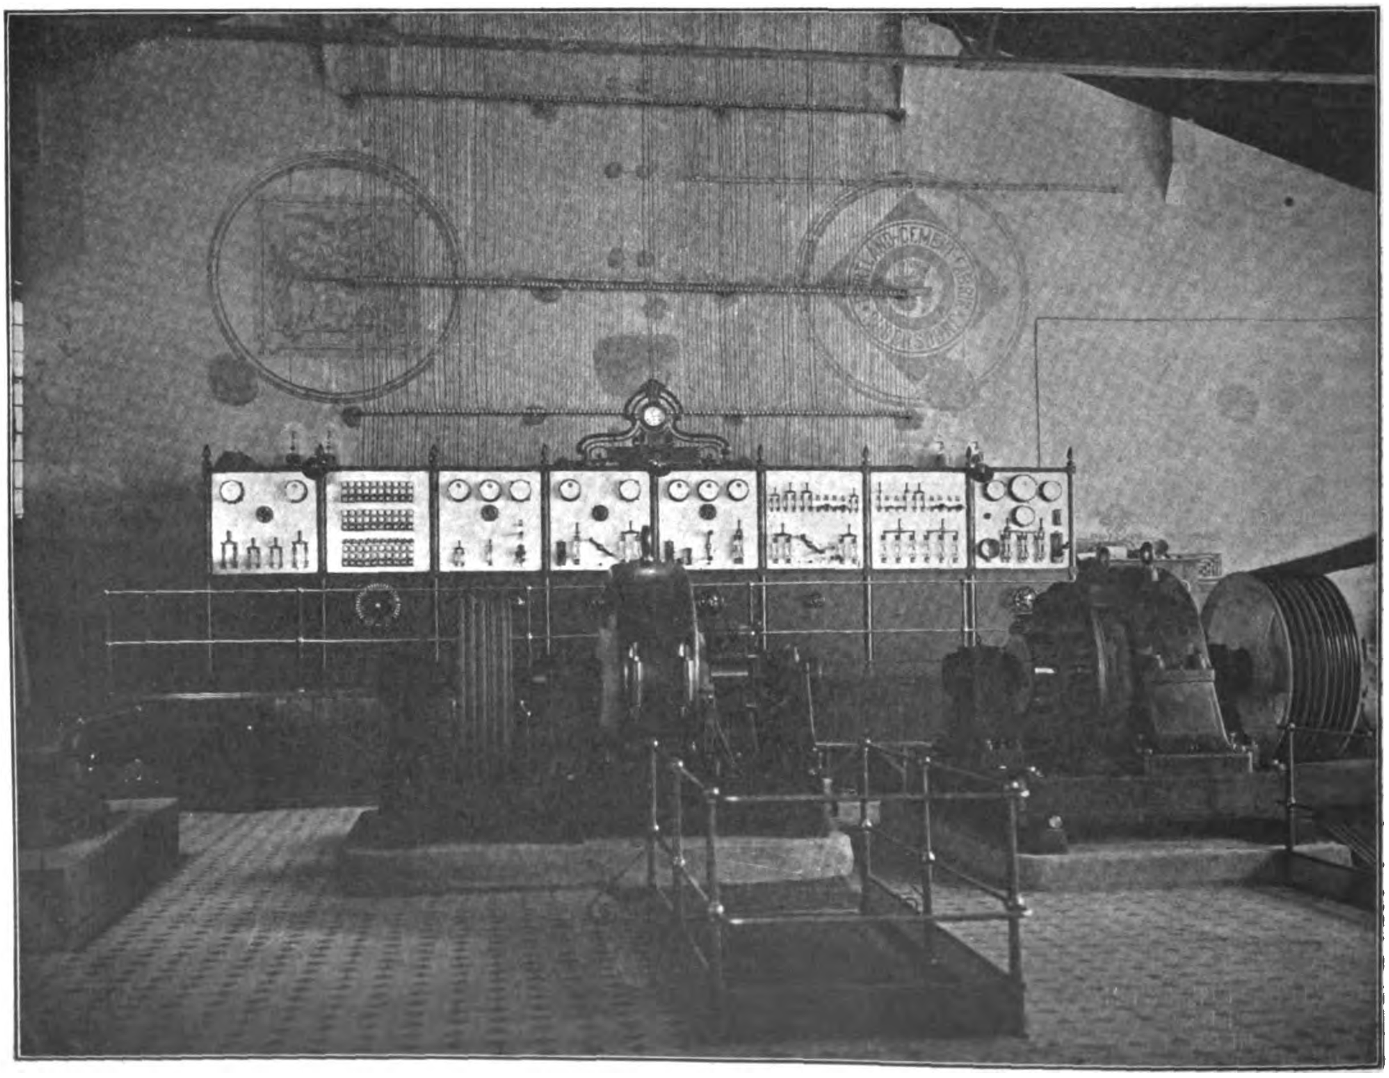


FIFTY-HORSEPOWER MOTOR, DRIVING CRUSHERS AND ELEVATORS.

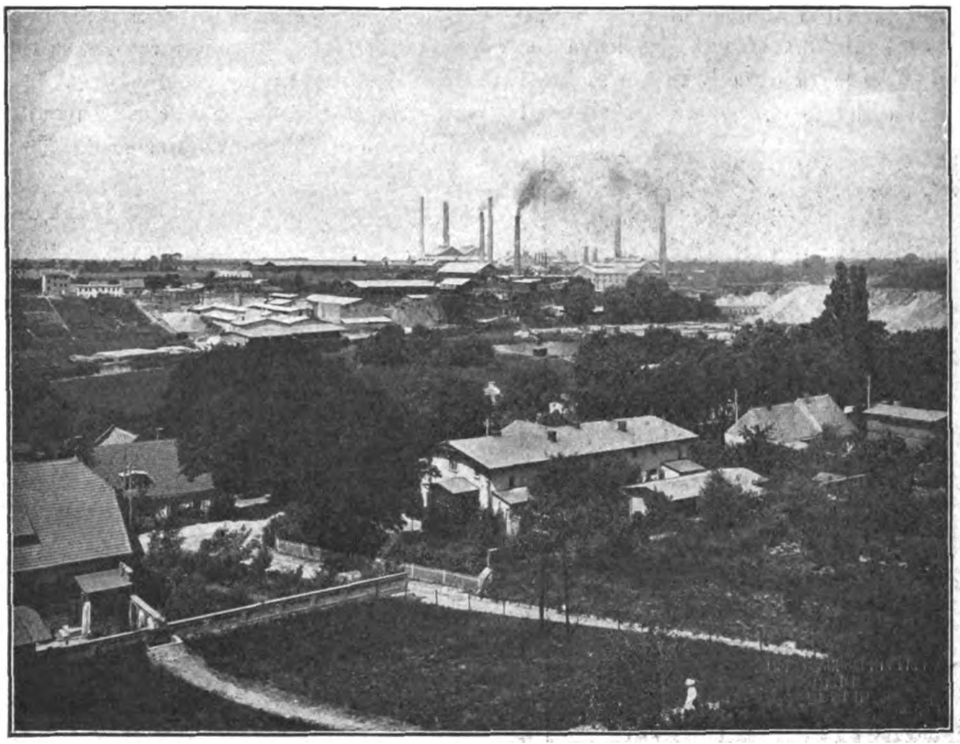
The most interesting point of mechanical operation, however, is the use of rotary kilns in the place of the pit or ring furnaces formerly used, which dispenses with any shaping and transporting work, thus reducing considerably the number of workmen. In fact, the material throughout the regular course of operations never once comes into contact with the shovel of a workman. After being raised to the higher stories by means of elevators, the raw materials (as well as the clinkers) are transported in vibrating chutes in a horizontal direction, whereas the finely ground substances are moved on by worm conveyors.

It will be readily understood that electric motors are specially adapted for the operation of the various kinds of machinery used in connection with this extensive process as well as of the conveyors and ventilating fans, though on account of the low speeds of these machines there is no possibility of using a direct coupling between the machines and motors.

One of the largest and most interesting German cement works in which electric drive has been recently adopted is the Rüdersdorf Portland Cement Fabrik



DIRECT-CURRENT MACHINES AND SWITCHBOARD, RÜDERSDORF PORTLAND CEMENT WORKS.



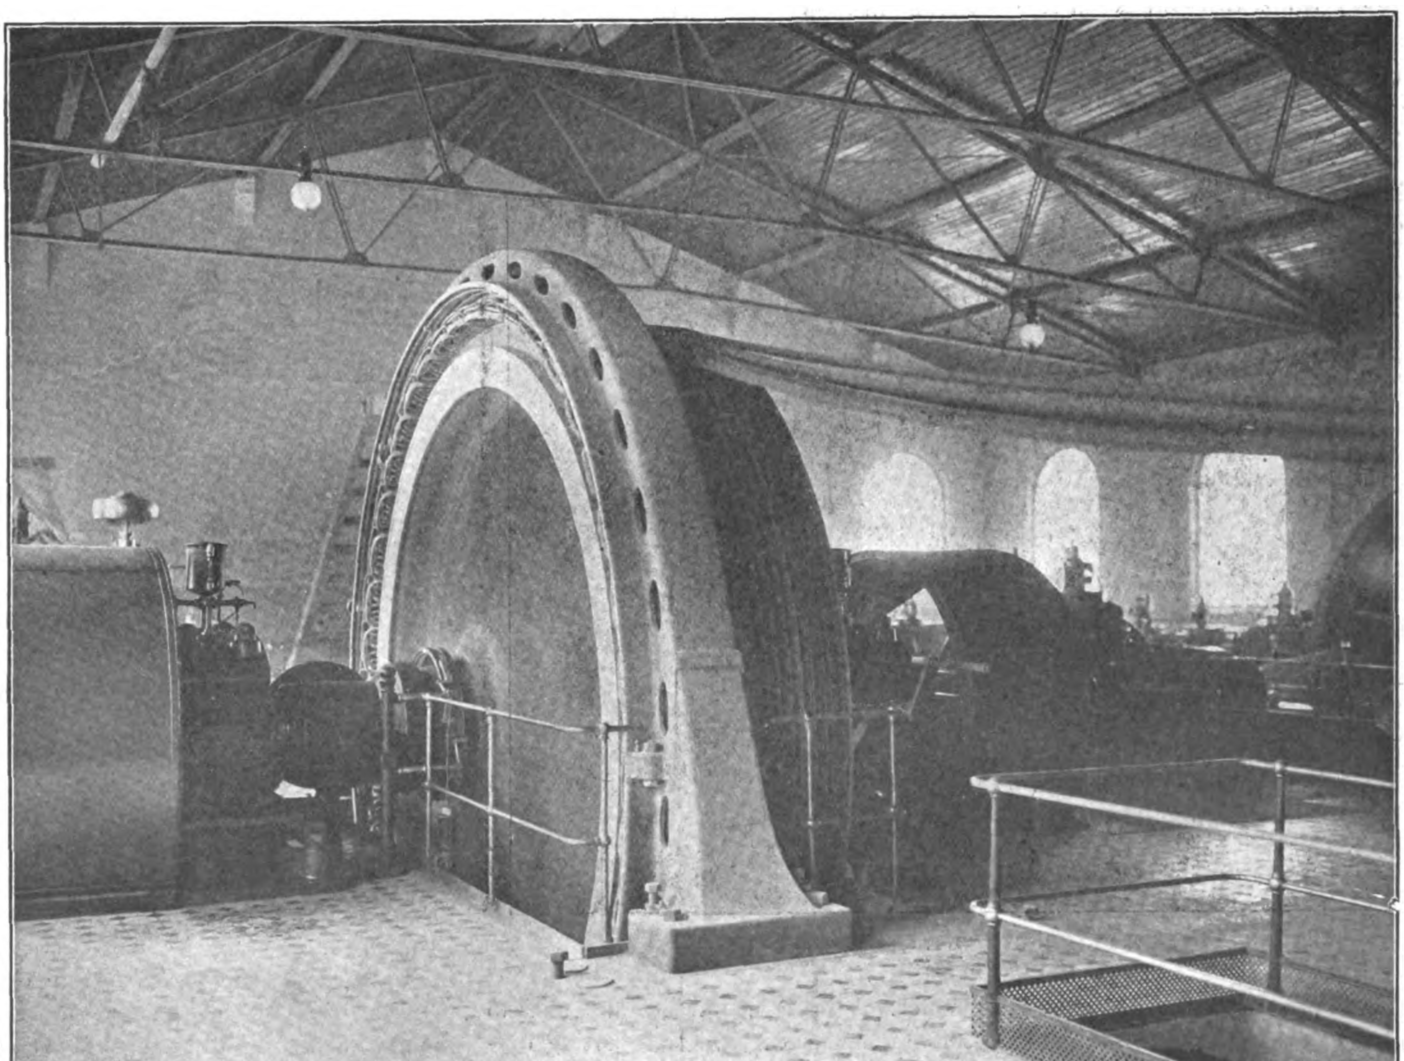
THE RUDERSDORF PORTLAND CEMENT WORKS.

(near Berlin), which has been recently electrified by the Siemens-Schuckert Works.

The equipment comprises a 500-volt polyphase generator of 700-kilovolt-ampere rating coupled to a steam engine, and two direct-current machines of 220 volts and 970 and 610 amperes, respectively. In addition to the supply of power to the factory these generators serve for lighting the works as well as supplying light and power to the neighboring community of Tasdorf. A storage battery is connected in parallel to the direct-current machines. No appreciable influence is exerted on the luminous intensity of the lamps actually in circuit by inserting the motors. The following short description of the manufacturing process will fitly illustrate the various uses of electricity made in this cement plant.

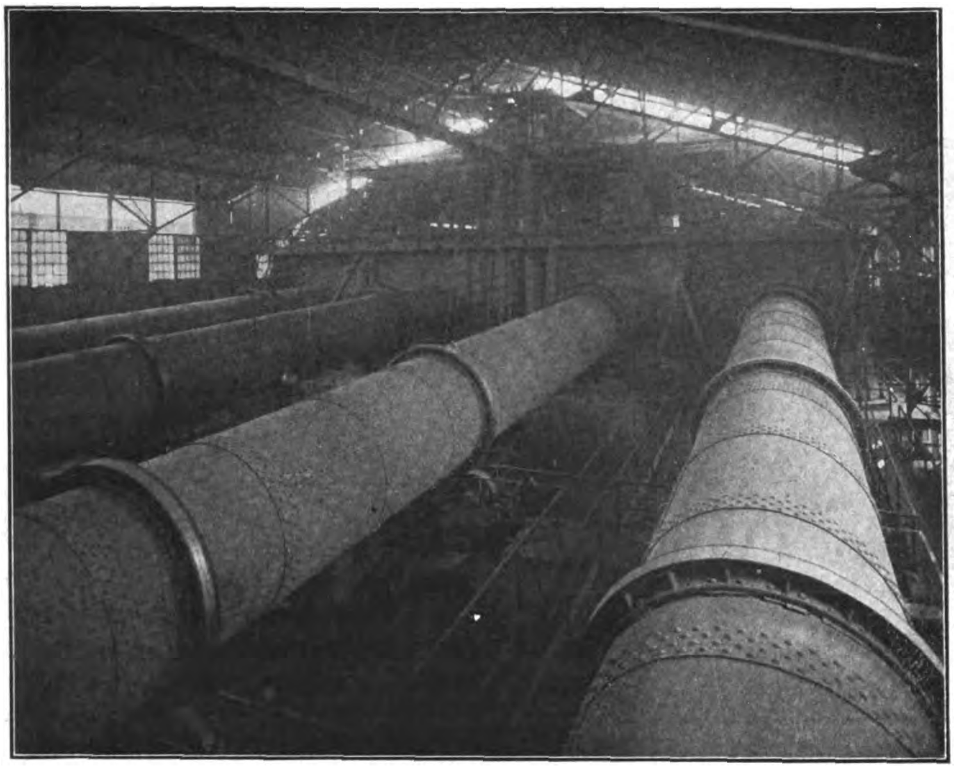
The first part of the operation consists of crushing the limestone in crushers and the slate in crushing rolls. After having been dried in drums the crushed raw material is mixed in predetermined ratios and ground in tube mills driven by two electric motors of 200 horsepower each. From the mills the powdered cement mixture is taken by electrically operated worm conveyors and elevators to the bins and bunkers on top of the four rotary kilns.

These kilns, constructed by the machine

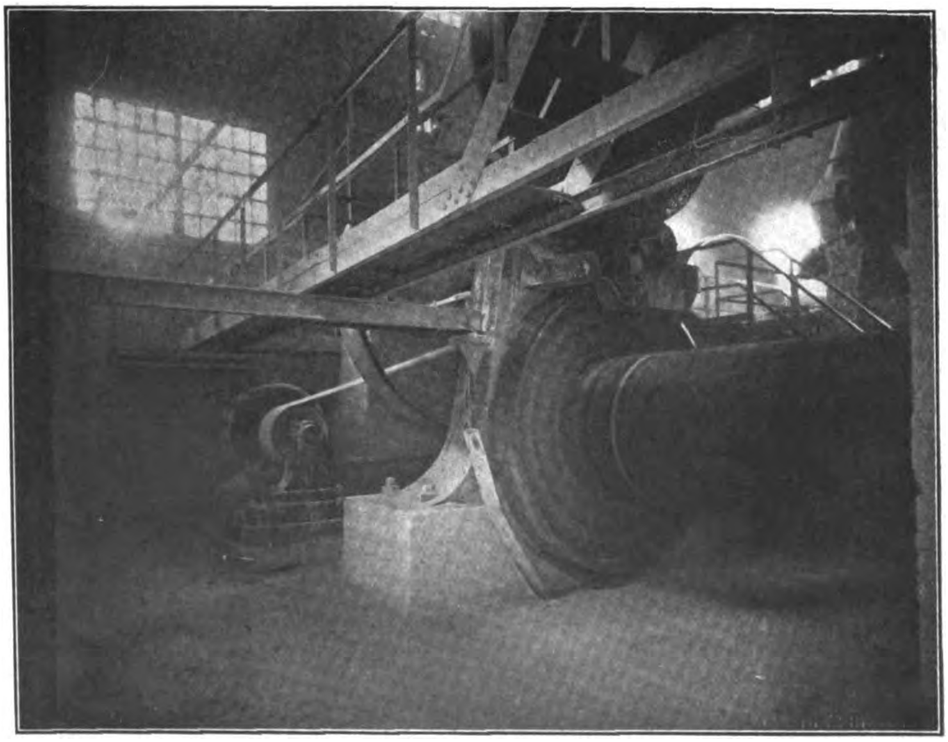


POLYPHASE ALTERNATING-CURRENT GENERATOR, 700 KILOVOLT-AMPERES, 500 VOLTS, : RUDERSDORF PORTLAND CEMENT WORKS.

works of Polysius, Dessau, are practically horizontal tubes twenty-six metres in length and 2.1 metres in diameter, rotating slowly about their axes. A steady supply of the powdered mixture is introduced at the higher end, while the fuel (in the shape of coal dust) is blown in by an air blast at the lower end. The mass is slowly heated to sintering, and during the rotation of the kiln, owing to the inclined position of the tube, moves toward the fire end, situated at a lower level, where the burnt clinkers of nut size leave the drum, to be taken directly to the inclined rotary cooling drums which are situated parallel to the rotary kilns on a lower floor. Each of the four kilns and coolers is operated by a thirty-horsepower electric motor. Electric motors are also used to drive the machinery for transporting, drying and grinding the coal as well as the blowing in of air and coal.



ELECTRICALLY DRIVEN ROTARY :KILNS, RUDERSDORF PORTLAND CEMENT WORKS.



MOTOR DRIVING CEMENT-GRINDING PLANT, :RUDERSDORF PORTLAND CEMENT WORKS.

The finished clinker is taken by vibrating chutes from the rotary coolers to the ball-tube mills to be ground to a fine powder by steel balls. These mills require two motors of 200 horsepower each.

An aggregate of 1,400 horsepower is used for power purposes in the plant described.

Third Avenue (New York) Receivership.

Frederick W. Whitridge, Federal receiver of the Third Avenue Railroad Company, in New York city, in an order signed by Judge Lacombe, is directed to pay William L. Ladd, state receiver of the New York City Railway Company, $42,772, with interest from May 1 last, at the rate of six per cent, the value of coal and other supplies rendered to Whitridge by Adrian H. Joline and Douglas Robinson, former receivers of the Third Avenue Railroad.

Receiver Ladd, in the petition which he presented to the court, valued the property at $51,000. Judge Lacombe, however, on the question of other property involved in the receivership controversy, appointed William L. Turner special master to take testimony and to decide as to its ownership.

New York State Public Service Commission.

The transportation companies reporting to the Public Service Commission for the First District gives the following list of accidents in November, with comparisons:

	Nov., '08	Nov., '07
Total accidents	3,992	4,037
Killed	36	45
Seriously injured	169	198

The total for November is 676 less than for the previous month, and the number of persons injured in getting on and off cars approximates one-half the figures for June and July.

Hell Gate to Be Bridged.

After the Pennsylvania Railroad has advanced farther with its terminal station and other improvements in and about New York city, work will be started on a bridge from Port Morris, a suburb of New York, to Queens County, Long Island. It will be used by the New York Connecting Railroad, a branch of the Pennsylvania system. As planned, the bridge in many respects is to be one of the most remarkable engineering structures ever proposed. With the approaches, it will be three miles long and span the Hell Gate ship channel with an enormous arch 1,000 feet in the clear.

FUEL ECONOMY TESTS AT A LARGE OIL-BURNING ELECTRIC POWER PLANT.

BY C. R. WEYMOUTH.

The writer desires to present the results of various fuel-economy tests at the Redondo plant of the Pacific Light and Power Company, near Los Angeles, Cal., which are of interest, both by reason of steam engines having been used as prime movers and because of the notable economy attained. Owing to the rigorous demands on commercially-operating power stations, an opportunity is seldom afforded to conduct uniform-load tests on a complete plant unit.

The station consists of three main units of 5,000 kilowatts each, the layout being in general on the panel system. For each plant unit there is one McIntosh and Seymour double horizontal and vertical, compound, condensing, automatic engine, size thirty-four and seventy by fifty-six inches, directly connected to an alternator. The rated speed is 100 revolutions per minute. Each engine has two horizontal high-pressure steam cylinders, and two vertical low-pressure cylinders, and is designed to operate at 175 pounds maintained throttle pressure, with 100 degrees F. superheat at the throttle. All steam cut-off valves are under control of the one shaft governor. This engine governor is subject to variation in speed, under the control of a McIntosh and Seymour electrically operated, speed-changing mechanism, situated within the governor and operated from the switchboard gallery.

Directly connected to each engine there is an ATB-sixty-pole, 5,000-kilowatt, 100-revolutions per minute, 18,000-volt, fifty-cycle, three-phase General Electric generator of the fly-wheel type. The revolving field is provided with squirrel-cage winding to prevent hunting. The generator field rheostats are motor-operated, with remote control from the switchboard.

In each plant unit are six Babcock and Wilcox boilers of forged-steel construction, arranged in three batteries of two each. Five boilers are intended for the nominal capacity of the unit, the sixth boiler for reserve. The boilers are twenty-one sections wide, fourteen tubes high, eighteen feet long, with three forty-two-inch drums, each containing a total effective water-heating surface of 6,042 square feet and designed for 200 pounds working steam pressure. Each boiler is equipped with one Babcock and Wilcox forged-steel double-loop superheater.

The boilers are provided with Peabody patent fuel-oil-burning furnaces, having a furnace depth of ten feet from boiler front to face of bridge wall. The burner head is placed at the bridge wall, the flame shooting toward the boiler front. The furnace diverges in the direction of the flame, corresponding to the angle of inclination of boiler tubes. Three burners are used per boiler, and are controlled from the boiler front.

Corresponding to each main generator, there is one seventy-five-kilowatt General Electric exciter, driven by means of a nine and seventeen by twelve-inch Harrisburg tandem compound, non-condensing, piston valve, automatic engine.

There are two Wheeler condensers for each main engine, located in the basement below the operating floor, one condenser being used for each low-pressure cylinder. The exhaust steam is led directly from the low-pressure cylinder into a thirty-inch exhaust main, and after passing through a ninety-degree sweep, drops directly into the condenser. The two condensers on each engine are cross-connected, so that both engines can exhaust into either condenser when the other is undergoing cleaning or repairs. Each condenser contains 5,002 square feet of cooling surface, consisting of three-fourths-inch brass tubes. In addition to the regular cooling surface of each condenser, there is provided in the upper compartment a series of tubes, comprising a Volz heater, through which the condensed water is pumped by the air pump at atmospheric pressure. The feed water is thus heated to within a few degrees of the temperature of the exhaust steam surrounding the upper tubes, thus compensating for the cooling action due to the lower condenser tubes.

Circulating water is supplied by three large engine-driven centrifugal pumps, connected to a common pump-discharge main. Branches from this main supply cooling water to all condensers. The outlets from all condensers connect to a common condenser-discharge main. Each condenser has one Edwards triplex, motor-driven air pump, size sixteen by ten inches.

After passing through the Volz heaters the condensed water is passed through suitably constructed filters for the elimination of the greater part of the entrained cylinder oil. The outlet of the filters is connected to the feed-pump suction main, the supply of water being maintained by an open equalizing hot well, which is also connected to the suction main.

Each unit has one Snow duplex, horizontal, boiler-feed pump, having a compound, non-condensing steam end and an outside center-packed water end. Each unit also contains one auxiliary, Goubert vertical, closed, feed-water heater, of the multiple-flow type, having 1,000 square feet of effective tube-heating surface.

The condensation in the main-engine superheating receiver coils is led to a simple duplex receiver pump. The hot water, at a temperature of about 360 degrees, is returned under boiler pressure to one or more of the boilers in the corresponding unit. The oily drips from receiver bodies are trapped to waste. From the auxiliary measuring tanks, the fuel oil is first pumped through a Goubert closed, multi-flow oil heater, in which the oil is heated to a temperature of approximately 150 degrees F., utilizing the exhaust steam from the oil-feed pump. From the oil heater the oil is led to an oil-pressure main and thence to the oil burners through a suitable system of piping.

An automatic system of regulation was employed for the firing of all boilers in the unit tested, hand firing being used on the remainder of the plant. The automatic system controls the supply of oil to the burners, the supply of steam for atomizing purposes, and the supply of air for combustion. This control is obtained through a steam-pressure regulator which operates a relief valve in the oil-pump discharge line, and is actuated by the variations in steam pressure in the boiler. This means of control causes a variation in the rate of burning oil comparable with the momentary load. With this system, all burner valves may be left wide open, or nearly so, and it follows that the intensity of firing increases or decreases simultaneously in all the boilers.

The supply of steam to burners for atomizing purposes is from a low-pressure steam main, the controlling valves at each of the burners being left wide open or nearly so. The variations in pressure in this main are governed automatically by variations of the oil pressure in the oil main. The regulator used throttles the supply of live steam to the low-pressure main, to produce the desired relationship of oil pressure and steam pressure on the respective burner heads. The supply of air for combustion is automatically regulated by a damper controller, operating a common rock shaft, connected to all

Abstract of a paper presented at the annual meeting of the American Society of Mechanical Engineers at New York on December 2.

boiler-outlet dampers. This regulator opens and closes all boiler dampers synchronously with an increase or decrease of oil pressure in the oil main.

This system is capable of such operation as to control all of its functions completely and automatically. In actual practice, however, it has been found desirable to watch closely the firing of boilers, to make certain that no external conditions, such as clogging of burners, distortion of flames by burners, variation in temperature of fuel oil, as fired, etc., are present to prevent the attainment of the highest possible efficiency. To minimize heat losses due to radiation, all live steam heat-radiating surfaces are covered with non-conducting covering three inches in thickness, and other surfaces are covered in accordance with the dictates of good practice.

OUTLINE OF TESTS.

The data and results given herein are based on the following tests:

a. Official fifteen-day variable-load test on No. 2 plant unit.

b. Uniform-load test at approximately 2,000 kilowatts output No. 2 plant unit.

c. Uniform-load test at approximately 3,000 kilowatts on No. 2 unit.

d. Uniform-load test at approximately 4,000 kilowatts output No. 2 unit.

e. Uniform-load test at approximately 5,000 kilowatts output No. 2 unit.

f. Test complete plant at variable load similar to the official test.

These tests are more fully described under their respective headings.

OFFICIAL FIFTEEN-DAY TEST.

The official test of this station was on No. 2 plant unit, and was made to determine the economy of the plant under contract conditions, as a basis for computing the bonus earned by the contractor, or the penalty due the owner. The result of this official test is now common knowledge, but not all the conditions surrounding the test have been heretofore published; and as the result of the official test on variable load is of interest for comparison with the results of the uniform-load test, herein presented, the writer desires to review the more important conditions attending the official trial. The contract placed the official test under control of a testing committee. The contractor's commercial-load economy guarantee was as follows:

The company guarantees * * * that the "first unit" * * * when operating on commercial-railway load, under ninety days' test, conforming to the conditions herein specified, will develop an average economy of 170 kilowatt-hours per barrel of oil.

The total net output of unit under test for each day will not be less than 60,000 and not more than 78,000 kilowatt-hours.

The main unit under test will be in operation during nineteen-and-one-half consecutive hours per day, and will be shut down four-and-one-half hours per day. The temperature of circulating water entering the condensers will never exceed seventy degrees Fahrenheit.

The power-factor of the electric load will be at all times between eighty and 100 per cent. Total load on 5,000-kilowatt alternator will never exceed 6,000 kilowatts. The load on 5,000-kilowatt generator greater than 5,000 kilowatts will last for an interval not greater than one-half minute duration; and there will be not to exceed ten such intervals during any hour that the plant is under test.

The load on the unit under test will be such as would be produced by the regular and normal working of the railway system to which the power is furnished by the purchaser, and varying within the limits herein described.

The load will not be manipulated so as to be either favorable or unfavorable to the showing of unit under test, within the limits herein specified.

It was optional with the contractor to insist on the operation of the test unit on a separate transmission line. This would have inconvenienced the purchaser, and for operating reasons a compromise was effected, it being agreed to operate the test unit during the official test in accordance with an agreed load curve, subject to certain upper and lower limits.

The control of the load during test was thus left entirely to the purchaser's station operator within the specified limits and subject to such momentary variations as would be imposed on the test unit by the fluctuation in load on purchaser's system. It was thus attempted to generate a total of 72,280 kilowatt-hours per day, with the understanding that should the total kilowatt-hour output up to any hour exceed that shown by the load curve, then, during the remainder of the test period, the load was to be modified to correct for any variation in the total output, so as to maintain the total daily output of the unit uniform and as agreed.

Endurance features having been established, by reason of the long period of operation previous to the test, the period of test was subsequently reduced from ninety to fifteen days. And, owing to certain advantages that might accrue to the contractor, such as superior economy due to shortening of test, the contractor agreed to deduct from the bonus otherwise due the sum of $50,000 in consideration of this reduction of test period.

The economy guaranteed initially included the provision for lighting the unit under test from energy generated by the test unit. Correction for lighting was made by deducting from the total net output of the unit under test an amount of power equivalent to 125 kilowatt-hours per day, and the reported economy is based on the net figure after making this deduction.

During the test the power for operating the air-pump motors, for operating motors connected to circulating pumps used for passing cooling water through engine bearings and guides, for operating electric motor in main engine speed-changing device, and for operating electric motor for controlling switches, was taken from the leads of the main generator in such a way as to compel the wattmeters to indicate only the net useful output of the unit.

It is only fair to state that, owing to the layout of the plant, certain auxiliary apparatus in connection with the plant was installed by the purchaser, power for which was not taken from the unit under test. These auxiliaries, with the exception of the circulating pumps, are not necessarily essential in the guarantee of power; that is, they may or may not be required in a power plant, depending upon local conditions, etc.

During the tests special weighing and receiving tanks were provided for the measurement of the fuel oil required by the unit under test. After weighing, the oil was emptied into a receiving and heating tank, the heating being done by steam from the unit under test, and from there conveyed by gravity to the oil-feed pump used for feeding oil to the burners.

All instruments were accurately calibrated and standardized. For purposes of the tests a total of twelve integrating wattmeters were purchased, and, after calibration in place under conditions of operation, it was finally decided to determine the power output by using one wattmeter in each phase of the generator, there being three reserve wattmeters. Meters were connected in the main winding of the generator between the grounded center of the winding and the winding itself.

A large corps of assistants and observers was employed during the tests. At one time a total of eighty persons was directly involved. The neutral observers, including the members of the graduating classes in electrical and mechanical engineering of the University of California, were under the direction of the chairman of the testing committee. In all details of the test care and accuracy, in keeping with the importance of the desired results and the amount of bonus money involved, were observed.

UNIFORM LOAD TESTS.

During the uniform-load tests the same general conditions prevailed as during the official trial, except as herein indicated. Though unofficial, the determination of fuel burned and power output during the uniform-load tests was still under control of the testing committee and the same corps of observers, although the wattmeter readings were taken less frequently, as a result of experience during the official trial. The calculated economies given are obtained from the readings made by the neutral observers. It should be stated, however, that the testing committee never completed any official report for these uniform-load tests, as the results of the uniform-load tests were of no consideration in determining the amount of bonus to be paid the contractor.

TABLE SHOWING RESULTS OF VARIABLE AND UNIFORM LOAD TESTS ON ONE 5,000-KILOWATT UNIT, ALSO VARIABLE LOAD TEST ON COMPLETE PLANT, AT REDONDO, CAL.

Designation of Test	Unit	Variable Load Average of 15-Day Tests	2,000-Kw. Load Test (Approximate)	3,000-Kw. Load Test (Approximate)	4,000-Kw. Load Test (Approximate)	5,000-Kw. Load Test (Approximate)	Variable Load Complete Plant Test

CURVES SHOWING ACTUAL AND RELATIVE FUEL ECONOMY AT FRACTIONAL LOADS, 5000-KW. UNIT.

Curve A Shows Fuel Economy at Various Fractional Loads in Kilowatt Hours per Barrel of Oil. Curve B Shows Relative Fuel Economy at Fractional Loads as Compared with Economy at Rated Load of 5000-kw.

VARIABLE-LOAD TEST OF THE COMPLETE PLANT.

During this test the entire plant was operated under commercial conditions of load, except that an attempt was made to follow on all three units the load curve used during the official test. The circulating pumps were supplied with steam from the various boilers, and all plant auxiliaries, including those omitted from official test, were included in the complete plant test. All these last-named auxiliaries were not in use at all times, however. The output of all units was determined by means of station wattmeters which have since been carefully calibrated by the purchaser, and the correction factors as found applied to the observed readings.

This test did not in any sense do justice to the plant, owing to operating conditions, as explained below, and for this reason the test was protested by the writer and at the time was discarded by the testing committee. The writer has since felt, however, that the result is of interest, and offers it with this explanation.

OPERATING CONDITIONS DURING TESTS.

During all the tests the plant was handled by the regular station operators under the control of the contractor's superintendent of construction.

The load was quite variable, necessitating constant adjustment of auxiliaries, oil burners, dampers, etc. On boilers of No. 2 unit, the automatic system of firing was used during the official test and during uniform-load tests. Control of oil burners and dampers on No. 1 and No. 3 units during the complete-plant test was by hand.

The contractor's experts were present during all tests, and cautioned the operators when necessary. Much credit is due them for the exceptional performance of representative apparatus.

During the official fifteen-day test certain unfavorable conditions predominated, for which no correction has been made in the stated economy. Owing to the accumulation of seaweed in the circulating-water pipe line, and the interruption of flow of circulating water through the condensers, there were intervals when either one or both condensers of the test unit operated at a reduced vacuum, and at other times it was necessary to run the engine non-condensing. Frequent shorts occurred on the lines, and again periods of excessive overload. During the official test, instead of following the comparatively smooth load curve agreed, momentary changes in load were of considerable magnitude. The actual load curves show a marked saw-tooth effect, momentary changes being so violent as to cause unfavorable economy, these variations in load not only affecting the economy of the prime mover, but also the performance of boilers, the continual change in rate of oil firing, air supply, steam supply to burners, etc., making it impossible to secure the best results, although the automatic-firing system employed on No. 2 unit no doubt greatly reduced such losses.

Certain of the uniform-load tests were of comparatively short duration. The results of such tests are therefore subject to slight error. The initial period of starting the uniform-load tests was determined by the testing committee, and while the writer has reluctantly assented to certain of these intervals, it will be self-evident that for certain of these tests the period allowed for warming up boilers before starting of test was not sufficient to eliminate all of the heat storage effect, and is not fully in accordance with the society's rules for conducting such trials. Previous to certain tests the boilers had been down for such lengths of time as to be practically cold. In other cases the boilers had been at stand-by for four or more hours previous to starting fires, except during the 3,000-kilowatt test where the boilers after previous day's run were kept up to steam pressure by intermittent firing. The results, therefore, from this standpoint are slightly unfavorable, the fuel consumption stated involving to some extent the fuel loss due to warming up the boilers.

The test for the 2,000-kilowatt load was made with three instead of five boilers in operation, as is the regular practice at this plant during any prolonged running at such loads. Owing to the short period of the test, it would have been impossible to keep the two idle boilers on the line and fire at intervals during the test in such a manner as to guarantee the same amount of heat storage in the idle boilers at both commencement and end of the test period. The amount of such loss due to stand-by of the idle boilers was therefore determined separately by actual measurement, and the resulting fuel loss is given in the accompanying table, corresponding to which due correction in economy has also been figured. The amount of this correction corresponds to the heat necessary to keep the two idle boilers continuously up to full boiler pressure. It is a fact, however, that the actual stand-by loss was less than this amount, owing to the reduction in the rate of heat radiation which takes place after the boiler has appreciably cooled.

During the uniform load tests it was necessary, owing to peculiar conditions of operation, to lower materially the power-factor of the unit under test in order to control the load on same more readily. Owing to this lowering of the power-factor below the range for which the wattmeters were carefully calibrated, an error was introduced in the readings, manifesting itself in a tendency of the meters to run too slow, thus indicating an output less than actual. Further, owing to the lower power-factor imposed on the main generator, the C^2R and other losses were greater than normal (80 to 100 per cent), causing a falling off in generator efficiency and consequent reduction of fuel economy.

During the complete plant test the head on the circulating pumps was measured and averaged in the neighborhood of thirty-five feet. This excess head is due to the fact that the purchaser met with certain reverses in the installation of the circulating water pipe line, making it necessary to install internal angle iron strengthening ribs. The suction and discharge piping is also subject to certain air leakage and to a considerable accumulation of seaweed both in the main suction line and in the suction line strainers. As a result of this condition, not only were the total head and duty imposed on the circulating pumps during the complete plant test exorbitant, but the quantity of circulating water handled was not quite sufficient for the most economical vacuum requirements when all three units were in operation. During all these tests certain unfavorable conditions existed as to the character of oil burned and the treatment of same preparatory to burning.

OBSERVED DATA.

In the accompanying table is given a summary of the observed data and the calculated results for the various tests, including averages of steam pressure at engine throttles, superheat at engine throttles, condenser vacuums, circulating water temperatures, etc.

FUEL OIL SPECIFICATIONS AND CORRECTIONS.

Certain arbitrary corrections were agreed on in formulating the guarantee of this plant, and the nature of such corrections should be well understood in order to gauge the value of the results herein given and the possible error that may have been introduced by reason of such corrections.

It is well known that with the poorer grades of coal, having excessive quantities of ash, sulphur, moisture and other volatile matter, there is a falling off in the furnace efficiency as compared with the combustion of the better grades of coal; so with crude oil having excessive quantities of moisture, sulphur and silt, or of low specific gravity, there is an appreciable falling off in the furnace efficiency as compared with a grade of crude oil of average quality. It is certain, however, that most of the losses due to foreign matter are less with oil fuel than with coal, but the exact extent of these losses is so far unknown.

During the preliminary negotiations for the Redondo plant the contractor's guarantee of 170 kilowatt-hours per barrel of oil was based on an average quality of Bakersfield crude oil, of known furnace performance, having the following specifications:

Specific gravity, sixteen degrees Baume.

Corresponding weight per barrel, 336 pounds.

Heat units per pound of oil calorimeter test, 18,500.

Moisture limit, one per cent.

Sulphur limit, one-half per cent.

On the day of closing the contract the purchaser insisted on testing the plant with oil secured from the purchaser's near-by wells; and while this oil never had been used during any authentic boiler trials, yet it was known to be of low gravity and low in heat units, to have considerable quantities of both moisture and sulphur, and in general to be a decidedly inferior grade of oil.

After some discussion a compromise was effected whereby the economy guarantee was allowed to remain as stated, the oil specifications being changed to the following:

Minimum specific gravity of oil fourteen degrees Baume.

Maximum specific gravity of oil, eighteen degrees Baume.

Agreed weight per barrel, 334 pounds.

Minimum heat units per pound of oil, 17,000.

Moisture limit, five per cent.

Sulphur limit, two-and-one-half per cent.

Silt, etc., limit, one-half per cent.

It was finally agreed that in addition to correcting on the heat-unit basis a further correction should be made for the presence of sulphur exceeding the limit of one per cent or moisture exceeding one-half per cent, and the purchaser should be penalized by deducting as oil from the weight of oil fired the weight of all moisture in excess of one-half per cent, all sulphur in excess of one per cent and all silt and other foreign matter.

It is a well known fact that oil, low in gravity, requires an excess of steam for preheating in the auxiliary suction tanks, both for the preliminary treatment of the oil in an attempt to remove the excess of moisture and silt by warming and also to enable the oil pressure pumps to lift this oil, under suction without danger of interruption in the pumping of oil to the burners. It is also well known that all crude oils are complex mixtures of various hydrocarbons, that distillation takes place to varying extents at all temperatures, and that the higher the temperature to which the oil is heated in an open tank the greater the loss due to such distillation.

It is further well known that the heavier the oil the greater the amount of heating necessary in the pressure heaters between pumps and burners, where heat is added to facilitate atomization of the oil and to economize in the amount of steam necessary for such atomization. In addition to the general falling off in furnace efficiency, due to the poorer grade of crude oil, there was a further and rather indeterminate loss due to the effect of sulphur and silt, which caused a slight clogging and corrosion of the burners and at times a distortion of the flames. The sulphur fumes from the products of combustion also escaped from the boiler setting, causing a serious annoyance to the firemen and necessitating an excess of air supply to overcome the trouble.

With our present knowledge of the combustion of oil fuel it is impossible to rationalize the results of the Redondo tests so as to determine exactly the true thermal efficiency that would have been attained had an average grade of crude oil been used. During the tests, as will be noted from the values given in the table, the grade of oil used was of very low specific gravity and contained excessive quantities of moisture, sulphur and silt. It is indisputable that an appreciable loss in efficiency resulted from the presence of these foreign substances, but owing to the arbitrary nature of the corrections made the plant economies herein stated may be in error by small percentages, the amount of which must remain indeterminate. This criticism will likewise apply to all similar tests which are not made with a grade of fuel recognized as standard.

As a matter of interest there are included in the table figures showing the plant efficiency, omitting the contract corrections; it must be borne in mind, however, as above stated, that these figures evidently represent a lower economy than would have been obtained with the standard grade of oil specified.

Considerably better economy would be expected in the uniform load tests than was secured in the official test, namely, 252.842 kilowatt-hours per barrel of oil. The actual results were not very much higher, however, for as already explained the period allowed for warming up the boilers before starting certain of the uniform load tests was not sufficient to overcome the loss due to radiation during the lay-over period, and the results were lower than they should be on this account. It should also be borne in mind that in the so-called uniform load tests the actual load varied from time to time, requiring a constant adjustment of oil burners, dampers and auxiliary apparatus, and while the magnitude of these variations was small, yet the variation in load was such as to cause a loss in economy as compared with an absolutely uniform load. The economy obtained at the various uniform loads is plotted in the curve shown. The economy at various fractional loads as compared with the economy at the rated load is also shown in the same diagram.

Inasmuch as the absolute economy at the various uniform loads is probably greater than reported, for reasons pointed out above, and as the correct economy at the uniform load tests would probably be a small but uniform percentage greater throughout all of such tests, it is fair to assume that the relative economies as shown are reasonably accurate, and for this reason the writer considers the curve showing the relationship of economies at various loads to be of greater value than the results of individual tests. There have also been plotted the points corresponding to three in lieu of five boilers, for 2,000-kilowatt load, for both of the above curves, as well as the economy obtained for the official test for the equivalent average load.

In studying these curves it should be borne in mind that the results given indicate the entire falling off in fractional load efficiency for the complete plant, being the multiplied effect due to various losses, such as electrical efficiency of generator, mechanical efficiency of engine, indicated economy of engine, auxiliary performance, and the greater effect at light load of dead load losses, such as heat radiation from exposed piping and other radiating surfaces, and the loss in efficiency of boilers owing to operation at fractional loads. As the total effect of all these losses is relatively small, it is in itself evidence of the high maintained steam economy of the prime mover at very light loads. The combined efficiencies of engine and generator are shown in the table, and as this falling off in efficiency at light loads is quite apparent it offers additional evidence as to the maintained indicated economy of engine at fractional loads.

A falling off in economy would be expected for the complete plant test of all three units as compared with the official test of No. 2 unit for many reasons; among these are the excess of head imposed on circulating pump, the deficiency in quantity of circulating water causing a severe loss of vacuum at intervals, and at the completion of test the operation of the plant non-condensing; the use of energy from the plant to operate a fifty-horsepower motor driving a duplex vacuum pump, necessary to remove air leakage in suction line; the use of energy in pumping water from the plant for operating motor-driven oil pumps in pumping oil from main oil tanks to auxiliary oil tanks; the use of energy from plant in pumping well water from the purchaser's wells to the plant; the energy used for pumping out sumps; the energy used for lighting various surrounding buildings and wharf; the necessity for hand control of firing the boilers of No. 1 and No. 3 units, the automatic system being in use on No. 2 unit only. Considering all of these conditions, the economy for the complete plant is very favorable indeed.

As having a bearing on the economy of the plant, the writer would explain that to conform to the contract load requirements during test, which are designated as the maximum requirements of the plant during commercial operation, and further to economize in the first cost of plant, the main engines were initially selected to have a normal rated capacity of 4,000 kilowatts in lieu of 5,000 kilowatts, the rated capacity of generators. The writer hoped thereby to obtain sufficiently increased economy at the lighter loads to offset the possible loss in economy due to overload. It has been shown that these 4,000-kilowatt engines are capable of carrying overloads in excess of 7,000 kilowatts. It appears, however, that it would have been a decided improvement had larger engines been selected, conforming more nearly to the rating of the generators. Due to the use of superheated steam, high fractional load economy would have been insured, the overload capacity still further increased, and superior economy maintained at loads considerably above rating.

Having no bearing on the economy of the unit, but as a matter of particular note, the writer would state that following the acceptance test on the plant, the engine for the No. 1 unit was operated under various conditions to determine the possibilities in case of an emergency. It was shown that the unit could be operated on either one, two or three as well as four cylinders. The running conditions were smooth and the successful parallel operation of the alternators was easily accomplished under all conditions. It was further possible temporarily to overload the cylinders in use during these special trials to such an extent as to produce in the neighborhood of 1,800 kilowatts per cylinder. The time required to remove a connecting rod in case of an emergency was found to be between one and two hours. It was also found possible to operate the entire engine on one condenser as well as both condensers, causing but a slight reduction in vacuum, the second condenser being available for repairs, etc. In case of difficulty through seaweed in the circulating water the engines were often run for a long time non-condensing.

The writer believes that this type and arrangement of prime mover offers features of flexibility that merit very careful consideration and enables the maintained operation of steam power plants, under both normal and emergency conditions, with a far less percentage of reserve capacity than is permissible with any other type of prime mover. The Redondo plant is today operating without any reserve capacity whatsoever, and since the completion of the work it has regularly operated under all conditions of service desired by the management.

As the maintained economy of any type of prime mover is of great importance, the writer is able to state that the station records so far fail to indicate any considerable falling off in economy as compared with test conditions. On the other hand, it is a matter of record that a complete plant economy has been attained, since operation of plant by purchaser, exceeding that herein reported. During the dry season this year and by reason of the large overload capacity afforded by these engines, the management has been compelled and has been able to operate this station under continuous load far in excess of that for which it was designed. The engines have been operated for long periods at overloads of seventy-five per cent above the rated loads, and during such periods only a slight falling off in economy has resulted, which was less than would be expected on account of the special way in which the engines were rated.

No. 1 and No. 3 units are now being equipped with an automatic system of firing similar to that on No. 2, and it is expected that the station economy will be materially improved thereby.

COMPARISON OF ECONOMY WITH COAL-BURNING PLANTS.

For the purpose of comparing the economies herein reported with those obtained in modern coal-burning stations, the writer has given the fuel consumption reduced to the corresponding British thermal units per kilowatt-hour; these figures are possibly subject to slight error, however, by reason of oil corrections already explained.

COMPARISON WITH TURBINE PERFORMANCE.

To the writer's knowledge, the best turbine performance on the Pacific Coast based on oil fuel is considerably under that found for the Redondo plant.

When comparing these results with economies reported for eastern turbine stations the writer would call attention to the necessity of making due allowance for the variation in the initial temperature of the circulating water. The average temperature obtainable in the vicinity of Los Angeles is from sixty to seventy degrees F., as compared with circulating water temperatures in the neighborhood of the freezing point, obtainable at times in many eastern stations, this lower temperature enabling the attainment of a considerably improved vacuum. Inasmuch as the steam turbine gains largely in apparent economy, due to increase in vacuum, similar reductions should be made in the stated economy of such plants, and correspondingly in the reported fuel consumption.

The writer believes that the performance herein indicated is noteworthy and warrants on the part of designing engineers a far more careful and thorough investigation as to the capabilities of steam engines, when used as prime movers, than is manifested in the practice of late years.

Steady Flames for Atmospheric Nitrogen Extraction.

Almost the reverse of the older form of electric arc employed in the Birkeland-Eyde process of nitrogen extraction from the air, in which a high-tension, alternating-current flame is blown into a veritable disc transversely to a direct-current magnetic field, is the method used by the Badische Anilin und Soda Fabrik, which has a working agreement with the Birkeland-Eyde Company. Long, thread-like arcs are employed to oxidize the nitrogen of the air. The air is blown tangentially so as to circulate spirally around the quietly-burning arc. In some examples of this apparatus recently exhibited the tubes were of glass, coated on the inner periphery by a wire spiral, which was in metallic contact with a knob at the top of the tube. At the bottom of the tube the wire spiral is only separated by a short distance from the other electrode, which is placed in the axis of the tube. When a 3,000-volt supply is applied between the two electrodes a spark jumps across and the arc travels rapidly up the tube. If, now, air is forced in at the bottom through a number of symmetrically-placed tangential nozzles, the arc burns quietly in the axis of the tube without touching the sides, and absorbs about four amperes at 3,000 volts.

The air charged with nitrous gases which leaves the top of the tube gives up some of its heat in raising the temperature of the fresh air about to enter the tube to some 500 degrees Centigrade, and the rest is employed in steam generation. The cooled gas is then mixed with water to form nitric acid, which, after treatment with lime, results in the required manuring material. An experimental installation on these lines was opened in Christiansand (South Norway) in the spring of 1907, with a total power of 2,000 horsepower. Three ovens are at work, with a length of flame of five metres, and each absorbing 600 horsepower. Alternating current of fifty cycles is employed, and the arc burns quietly and reliably.

$6,650,000 Boston Elevated Issue.

An issue of $6,650,000 new stock by the Boston Elevated Road for the construction of the new Cambridge subway and the new elevated road from the North Station to the West Boston Bridge, has been authorized by the Railroad Commission. The stock will be sold at $110 a share.

Phoenix Glass Products.

The Phœnix Glass Company, of New York, Pittsburg and Chicago, has retained the Bureau of Illuminating Engineering, 437 Fifth Avenue, New York city, to act as consulting and designing illuminating engineers in the matter of designing or redesigning glass globes and reflectors manufactured by the company, so that beauty and utility may be blended. Albert J. Marshall, chief engineer of the bureau, will have direct supervision of this work.

As the result of this arrangement, the Phœnix company will be prepared to supply glassware for any class of service and for any illuminant, which will not only be ornamental, but will also give utilitarian results. In carrying out these ideas, the effect of light on the eye will receive very careful consideration. The Phœnix Glass Company, through the bureau, will be pleased to supply technical data regarding its product.

FINANCIAL REPORTS OF ELECTRICAL COMPANIES.

AMERICAN TELEPHONE.

The report of all the Associated Bell Telephone operating companies (not including the long-distance lines) of the American Telephone and Telegraph Company for the month of October and ten months ended October 31, 1908, compares as follows:

	1908.	1907.
October:		
Telephone rev.	$10,261,800	$ 9,893,300
Oper. and mt. exp.	7,401,000	7,252,100
Net from oper.	$ 2,860,800	$ 2,641,200
Sundry earnings (net)	430,400	383,500
Total net	$ 3,291,200	$ 2,024,700
Interest	621,400	630,400
Balance for divs.	$ 2,669,800	$ 2,394,300
January 1 to October 31:		
Telephone rev.	$99,168,600	$93,893,000
Oper. and mt. exp.	72,515,400	69,413,400
Balance from oper.	$26,653,200	$24,479,600
Sundry earnings (net)	4,296,600	3,806,900
Total net	$30,949,800	$28,286,500
Interest	6,388,400	5,926,900
Balance for divs.	$24,561,400	$22,359,600

The maintenance charges and taxes included in the above expenses for October and ten months, compare as follows:

	1908.	1907.
Month October:		
Maintenance	$ 2,789,800	$ 2,715,700
Taxes	455,400	338,100
Total	$ 3,245,200	$ 3,053,800
January 1 to October 31:		
Maintenance	$27,797,400	$25,826,900
Taxes	4,285,800	3,686,500
Total	$32,983,200	$29,513,400

CHICAGO RAILWAYS.

The Chicago Railways Company reports earnings for the month of September, compared as follows:

	1908.	1907.
September:		
Gross	$960,567	$927,882
Expenses	788,808	618,946
Net	$171,759	$308,936

The state tax, amounting to $176,000 for the year, is included in the above expenses for 1908, against $16,000 in 1907, which was the month's proportion last year. The statement, therefore, is $160,000 better than appears.

October, November and December earnings show a better gross.

KEYSTONE TELEPHONE.

The report of the Keystone Telephone Company, of Philadelphia, for the month of November and five months ended November 30, compares as follows:

	1908.	1907.
November gross	$ 88,377	$ 88,120
Expenses and taxes	42,701	48,080
November net	$ 45,676	$ 40,040
Five months, gross	439,383	437,280
Expenses and taxes	217,455	231,811
Five months, net	$221,928	$205,469

NORTHERN OHIO TRACTION.

The report of the Northern Ohio Traction and Light Company for the month of November and eleven months ended November 30, compares as follows:

	1908.	1907.
November gross	$151,934	$146,123
Expenses	87,976	88,180
November net	$ 63,958	$ 57,943
Charges	44,012	43,351
November surplus	$ 19,946	$ 14,592
Eleven months, gross	1,731,015	1,761,196
Expenses	1,001,277	1,013,466
Eleven months, net	$729,738	$747,730
Charges	479,795	469,881
Eleven months, surplus	$249,943	$277,849

CUMBERLAND TELEPHONE.

The report of the Cumberland Telephone and Telegraph Company for the month of November and eleven months ended November 30, compares as follows:

	1908.	1907.
November gross	$ 535,062	$ 535,794
Expenses	286,931	302,041
November net	$ 248,131	$ 233,753
Charges and taxes	44,638	38,244
November surplus	$ 203,493	$ 195,509
Eleven months, gross	5,606,155	5,395,832
Expenses	3,212,414	3,307,178
Eleven months, net	$2,393,741	$2,088,654
Charges	430,896	430,918
Eleven months, surplus	$1,962,845	$1,657,736

New Monorail System.

Commissioner Bassett, of the Public Service Commission, examined on December 18 the plans of a new monorail system. They were submitted to him by the inventor, E. W. C. Kearney, engineer and managing director of the Kearney High-speed Railway Company, Limited, of London.

It is claimed that if the system were adopted it would result in the construction of subways at less than half the present cost, in absolute safety from near-end collisions, and in a large saving of time in transit.

Wireless Telegraph Rates Abroad.

The international wireless-telegraphy treaty of November 3, 1906, the supplementary agreement, the final protocol and the agreement for executing the provisions of the treaty have, up to the present time, been ratified by Germany, Belgium, Brazil, Bulgaria, Denmark, Spain, Norway, Holland, Roumania, Russia and Sweden. The treaty, the final protocol and the agreement for executing the provisions of the treaty have been ratified by Great Britain, Japan and Mexico, and recently the latter company has also ratified the supplementary agreement. Great Britain in the ratification of the treaty includes Canada, Australia, New Zealand, the Cape Colony, Natal, Transvaal, India, and all the other British colonies and protectorates, with the exception of Newfoundland and the Orange River Colony.

The American Consul-General at Berlin, A. W. Thackera, writes that the charges for wireless-telegraph messages at the German coast stations are as follows:

Besides the regular telegraph rates in Germany of five pfennigs (1.19 cents) a word, minimum price fifty pfennigs (11.9 cents), there is a charge of fifteen pfennigs (3.57 cents) a word, minimum 1.5 marks (35.7 cents), and if the message is sent to a steamer which can be reached from the coast station an additional toll of thirty-five pfennigs (8.33 cents) a word, minimum 3.5 marks (83.5 cents), is charged. These charges can be prepaid at any of the German offices.

Until the international list of wireless-telegraph stations, which is to contain the charges for sending wireless messages, is published, the fee for coast stations outside of Germany, according to information obtained from the Gesellschaft für Drahtlose Telegraphie of Berlin has been fixed at forty-eight pfennigs (11.42 cents) a word, with a minimum of 4.8 marks ($1.14).

Cleveland Tractions.

The three-cent fare in Cleveland for the six months, May 1 to November 1, produced gross earnings of $2,450,609, but a net deficit of $70,915.

The report of the three-cent fares for October will show $406,600 gross earnings, with a deficit of $29,547. This includes attorney fees of $9,000. These figures and those for November and December, which will be completed by January 15, will be considered by Judge Taylor and the receivers as their basis for deciding on the demand for an advance in fares by the stockholders.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

THE MANUFACTURE OF METALLIC LAMP FILAMENTS.

The serial article of Engineer Duschnitz, already noted in these columns, is here continued. A twisting of the filaments in a certain direction frequently takes place during the reduction process by direct current (when they are usually suspended in the reduction chamber in the form of a stirrup) and renders them unfit for use. The Auer Gesellschaft of Berlin has investigated this phenomenon and found that the twisting is due to the influence of the magnetic field of the earth, respectively of the work-room, on the filament through which direct current is flowing. This influence can be prevented by compensating the magnetic field or by magnetically screening the reduction apparatus; that is, surrounding it with iron. The latter method appears to be the most practicable. A twisted filament may be corrected by placing it in such a position that the earth's magnetism affects it in the opposite direction from that exerted in the beginning. Another and unpatented method of making this twisting absolutely impossible is to lengthen the two binding posts, from which the filament is suspended, to the right and left of the filament and line the two shanks with thorium oxide, this for the purpose of preventing the filament from becoming welded to the shanks when it is at white heat and should show a tendency to twist. A special method of glowing the filaments is employed by the Allgemeine Elektrizitaets Gesellschaft. During their reduction in hydrogen or other gases the resistance of the filaments decreases considerably, frequently to one-tenth. Thus the resistance may easily diminish so rapidly that the filament will be melted. To prevent this, the above firm uses resistances of fine iron wire (about 0.1 millimetre) enclosed in tubes filled with hydrogen, in series with the filaments. The energy becoming free on account of the gradually decreasing resistance of the filaments is taken up by these devices, so that the current flowing through the filaments cannot exceed a certain value, and the reduction apparatus can be operated without attention. The glowing is controlled at intervals, preferably by means of an ohmmeter, and continued until the resistance of the filaments has decreased to a certain definite value. Of great importance are devices for bending the filaments. These are too brittle when cold, and have to be brought at least to red heat. In free air the filaments would oxidize when heated, and the bending, therefore, has to be accomplished in a vacuum or an indifferent gas. In the method of the Auer Gesellschaft the difficulties of manipulation are very small. The arrangement consists of a tube-like vessel with a sufficiently large opening at the bottom to permit the introduction of the filaments and necessary tools and their easy manipulation, while a gas that does not affect the heated filament is made to flow through the vessel from the top and prevent the entrance of air. If a gas of low specific gravity, as hydrogen, is chosen, a current of about one litre a second is sufficient. If a heavy gas, as carbonic acid gas, is used, the vessel should be open at the top, but in this case the execution of the work will be more difficult.—*Translated and abstracted from Elektrotechnischer Anzeiger (Berlin), November 19.*

RECENT PROGRESS IN THE STUDY OF ATMOSPHERIC DISCHARGES AND LIGHTNING ARRESTERS.

The effects of excessive tensions in transmission lines due to lightning discharges have been the subject of careful study during the last few years, and the results obtained now permit a judicious choice of lightning arresters. Investigations have been made chiefly of the duration of disturbances due to a lightning discharge, of the value of the resulting tension, the maximum value of the resulting current, the normal frequency of the lightning discharge and the quantity of electricity involved in it. The duration of the disturbances was measured by recording the sparks crossing a gap placed in the circuit on a rapidly-revolving photographic plate, and the average obtained in a great number of tests was one-one-thousandth of a second; the longest noted lasted four-tenths of a second. The duration of a lightning stroke has been stated by some investigators to be as much as half a second, but there must have been an error in their observations, due to the almost simultaneous occurrence of a number of discharges. The maximum value of the over-tension in the line is evidently the result of a direct lightning discharge, and it may assume any value from zero to maximum. Observations and reasoning show that, all other things being equal, the line is subject to the highest tension at the point nearest to the inducing cloud and that it diminishes in both directions from this point. This observation demonstrates the utility of lightning arresters along the line. If the inductance of the line is such that the potential at the insulators remains at sparking value during a time equal to the dielectric retardation, the spark will jump over the insulator and pole to the ground. The discharge current can be calculated according to the usual formula: $I = V\sqrt{\frac{C}{L}}$, C and L representing capacity and inductance of the line per unit of length. This factor is of importance only in its bearing on the internal resistance of the lightning arresters, and it is sufficient to state that they are capable of withstanding an average intensity of 0.3 ampere per volt applied. The frequencies observed varied between 840 and 4,000 cycles per second, the number 3,000 being most frequently observed. In the vicinity of an inducing cloud the frequency reached 1,000,000 cycles per second. In accordance with theory, the discharge waves flow through the line the quicker, the higher the frequency. The quantity of electricity involved is determined by the application of the formula $Q = \sqrt{\frac{Jt}{R}}$, t being the duration of the discharge in a test fuse, J the energy in joules necessary to raise to its melting point one centimetre of the fuse metal, R the resistance in ohm-centimetres of this metal. By examining these results more closely with reference to the construction of protecting devices, it will be found that the characteristic elements of the latter are their sparking potential, the elements on which their discharge current depends, and the elements on which the duration of the discharge is dependent. They must, therefore, meet the following conditions: Their sparking tension must be lower than the voltage the insulators can safely withstand; they must have a small impedance, and they must be sufficiently strong to withstand a prolonged discharge. Of all the types of apparatus known these three requirements are best fulfilled by electrolytic lightning arresters, the construction of which is well known.—*Abstracted and translated from L'Electricien (Paris), November 21.*

THE UTILIZATION OF WIND AS A MOTIVE POWER FOR DYNAMOS.

This problem has attracted the attention of many investigators. Professor La Cour obtained the first practical results in methodical experiments carried on under the auspices of the Danish Government. The plant erected by him in 1904 at Askov has been replaced by a new and improved one. The new windmill has four wings 2.5 metres wide and 7.4 metres long. The axis of the motor is thirteen metres above ground level. The electrical installation comprises two direct-current dynamos of twelve horsepower each, and a storage battery which is charged by the dynamos and supplies current to lamps and motors. The average power obtained is twenty-one horsepower. According to Professor La Cour, the windmill with four wings is the most efficient one. The ends of the wings should turn with a velocity two-and-one-half times greater than that of the wind. The wings should be arranged at right angles to each other and should be provided with transverse adjustable sheets having an inclination of ten to twenty-five degrees. The power of this type of mill can be calculated by means of the formula:

$$P = \frac{Sv^3}{1{,}250},$$

P being the force in horsepower, S the surface of the wings in square metres, and v the velocity of the wind in metres per second. Thus a mill with a wing surface of forty-eight square metres develops eight horsepower at a wind velocity of six metres per second, and sixteen horsepower at a wind velocity of eight metres per second, which is quite common in Denmark. A company for the atmospheric production of electrical energy has been formed in Denmark, and so far has installed some forty plants. When the storage battery is being charged and the tension of the dynamo falls below that of the battery on account of a decrease in the speed of the mill, a device known as the La Cour relay automatically interrupts the circuit to the accumulators, so that they cannot discharge through the dynamo, and closes the circuit again when the tension rises. In England W. O. Horsnail has also studied this subject. He recommends the use of a dynamo with a special winding so calculated that the tension rises only slowly under a great increase of speed. For this purpose a few turns of series winding in a direction opposite to that of the shunt winding may be used. The Oerlikon Company, of Switzerland, has likewise occupied itself with the practical solution of this problem, and has devised a system of connections which makes the operation of the plant entirely automatic, and supervision unnecessary.—*Translated and abstracted from L'Electricien (Paris), November 28.*

THE PRESENT POSITION OF THE VARIOUS TYPES OF INCANDESCENT LAMPS.

Prof. W. Wedding has recently carried out an exhaustive test at Charlottenburg on some 200 lamps of metallized-carbon, tantalum and tungsten-filament types. The lamps were suspended vertically from wall brackets, and vibration avoided as far as possible. Most of the light measurements were made in an Ulbricht globe photometer, one metre in diameter. The accompanying table gives some of the results of these tests, the figures for each group of similar lamps of the same make being averaged.

		Candlepower at Start.			
		Horizontal Hefner C. P.	Spherical Hefner C. P.	Useful Life in Hours.	Average Watt Consumption.
Metallized carbon filament		16.8	13.34	322*	34.2
		52.9	40.2	434	100.7
		24.3	17.8	733	54.7
Tantalum filament.		15.1	11.6	867	27.3
		23.1	17.5	1,552	41.4
		51.0	38.4	1,685	85.7
Tungsten filament	No. 1	26.3	20.0	1,651	27.8
	3	27.9	20.3	665	31.0
	6	28.5	22.8	1,819	36.0
	7	30.3	21.0	669	50.7
	9	35.3	28.7	1,217	38.9
	11	37.5	28.2	1,492	38.5
	14	54.2	40.8	1,014	61.1
	15	54.3	41.2	756	60.2
	16	55.8	44.5	1,111	66.9
	20	99.8	79.2	1,766	110.5
	21	116.5	97.5	413	124.1

*This short life is partly due to the lamps being 107-volt ones run on a 110-volt circuit.

The useful life of the lamp, given in Column 4, is taken to be the number of hours in which the candlepower falls off by twenty per cent, where such a falling off takes place; but where, as in the case of most of the tungsten lamps, this twenty-per-cent reduction is practically never reached, the useful life is taken as the average number of hours, after which the filaments broke and could not be made to connect again. Taking the normal tantalum or carbon lamp as a sixteen-candlepower unit, and the normal tungsten lamp as a twenty-five-candlepower unit, the average consumptions are 34.2 watts, 27.3 watts and thirty-two watts, respectively, in the three classes; or, for lamps of equal candlepower (twenty-five) the figures are 54.7, 41.4 and thirty-two watts.—*Abstracted from the Electrical Review (London), November 27.*

THE CONDENSER EFFECT OF THE TELEPHONE AND MEANS FOR ELIMINATING IT.

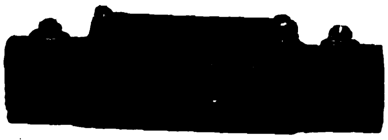
When over-tensions occur in telephone lines, says Prof. W. Peukert in this article, a current passes through the human body, for the telephone must act as a condenser, the copper wire winding forming one of its armatures, the human body the other, and the hard rubber casing of the telephone the dielectric. He has demonstrated his theory by experiments and measurements. Over-tensions in telephone circuits are of frequent occurrence, their chief causes being atmospheric conditions and the presence of high-tension lines, and the current caused to flow through the body might be detrimental to the health of sensitive persons who frequently use the telephone. The effect may be diminished by establishing a special earth connection through a condenser, or by decreasing the capacity of the condenser formed by the telephone and the body. The protection afforded by the former method will be the greater the larger the capacity of the condenser, as the current flowing through the body will then be smaller. This may be done by surrounding the telephone receiver with a metal layer and connecting the same to the ground. The same protection will be afforded by connecting two condensers in series with the binding posts of the telephone and grounding them. A still greater safety will be attained if grounded condensers are also connected to the secondary coil of the microphone transformer. The other method of decreasing the condenser effect is to insulate the human body from the ground. In this case two condensers—telephone and human body, human body and ground—are connected in series, and the current flowing through them is diminished. Both methods may be used in conjunction, but by none of them can the condenser effect be eliminated entirely; it can only be decreased to a certain degree. —*Translated and abstracted from Electrotechnische Zeitschrift (Berlin), November 26.*

INDUSTRIAL SECTION

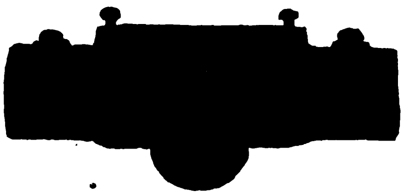
ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

Paiste Pipe Taplets.

The H. T. Paiste Company, Philadelphia, Pa., has developed an entirely new line of conduit fittings, which has been trade-marked "Pipe Taplets." This line has been designed so as to greatly simplify the work of the wireman, and to carry out the idea of uniformity as far as possible.

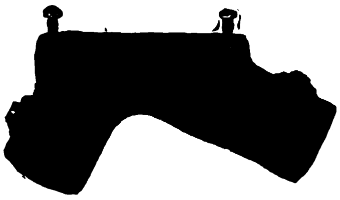


TYPE "C"—ONE-HALF-INCH CONDUIT.

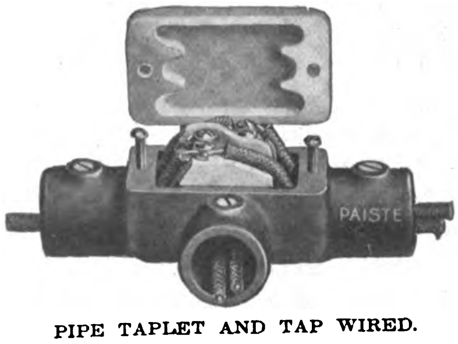


TYPE "T"—ONE-HALF-INCH CONDUIT.

The taplets are uniform, not only with respect to all covers and fittings, but also with all styles of Fielding molding, receptacles and rosettes which are now in daily use, and which are carried in stock by supply men. The pipe taplets are designed with an opening of such shape that the Fieldings can be used, and this common opening applies to the several types for one-half-inch, three-quarters-inch and one-inch conduit.



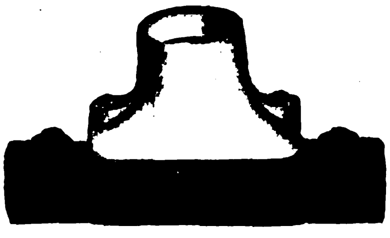
ELBOW FOR ONE-HALF-INCH CONDUIT.



PIPE TAPLET AND TAP WIRED.

The pipe taplet is attached to the conduit by pipe threads located inside the sleeve. There is also a set-screw method of adjusting which enables a line-up of absolute trueness.

The taplets are made in several types, Type C being for use where the lines run straight through; Type E, the end fitting; Type A, for making an end drop; Type B, a side drop, and Type T, for making a branch. In the elbow fitting, however, an entirely new type has been devised. This elbow can be used not only for making a short right-angled turn, but more particularly for a pull outlet. The opening is placed on the outside of the bend, and all inside lines are easy curves with smooth surfaces. This design is such that the wires can be pulled straight through, and then fed through the other arm without abrasion or other injury. The elbows are galvanized inside and out, and are always furnished with necessary soft-rubber gaskets and plain steel covers.



TYPE "C" WITH NO. 50,724 FITTING.

TWO-HOLE PORCELAIN COVER.

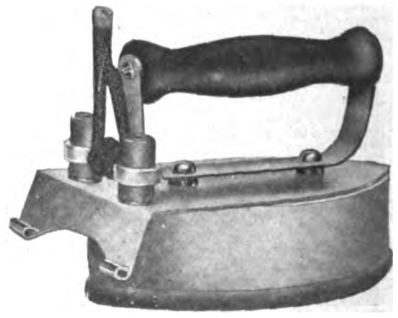
TEN-AMPERE SWITCH ATTACHED TO PIPE TAPLET.

In using these pipe taplets with the standard Fielding receptacles and rosettes, the Fieldings are wired just as is usual with molding. The button part rests on the two inwardly-projecting lugs in the pipe-taplet opening, and the wires are looped up and set under the receptacle set-screws, and the cover fastened on with two brass screws, provided with each pipe taplet.

An additional fitting has been designed that will take care of all types of pipe taplets and snap-switches. This switch fitting is attached to the pipe taplet with long brass screws. A loose yoke piece is fastened loosely to the switch. The switch is set down on the fitting so that this loosely-hanging yoke-piece slips through the rectangular recess, and the whole is turned so that the handle of the switch is square with the pipe taplet. By tightening up the two screws that hold the switch to the yoke, the whole is securely fastened.

The Watson Economical Electric Flat-Iron.

A radical departure from the general type of electric flatiron has been made by the W. N. Durant Company, of Milwaukee, Wis., in its Watson iron, for which much greater efficiency as well as durability is claimed. Instead of using a resistance heating-unit, the iron is used exclusively on alternating-current circuits and employs simply a magnetic coil of fireproof wire embedded in a casting of proper material. The heat is developed by hysteresis in the entire casting body, and, as no part is ever hotter than the working surface, all danger of burning out is entirely eliminated.



THE WATSON ELECTRIC FLATIRON.

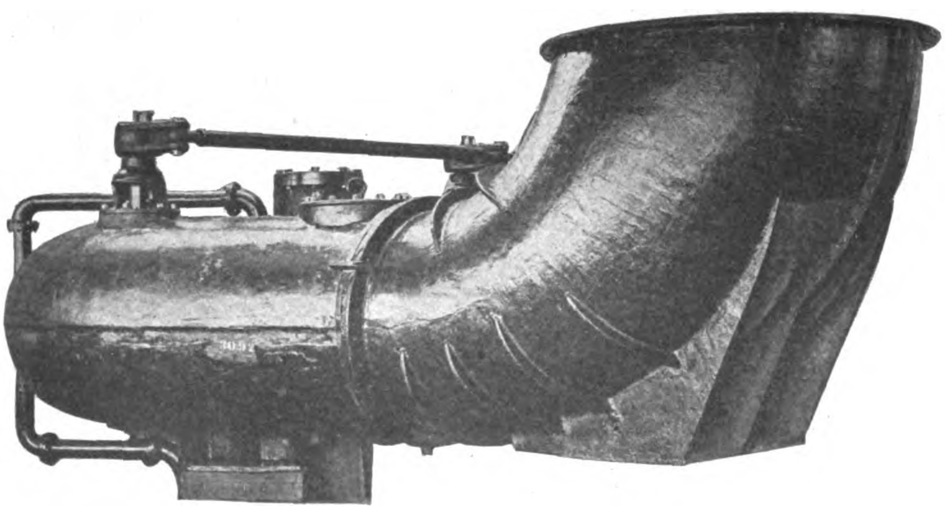
A still greater advantage claimed for this iron is its economy in consumption of current. The six-pound iron, which is the most popular size, consumes less than 450 watts under working conditions, and the seven-and-one-half-pound very little more. Furthermore, the device is so insulated as to have a large heat-storage capacity, and will retain an ironing temperature for a considerable time after disconnection. But four minutes is required to bring the iron to a working heat distributed evenly over the entire bottom surface.

Another distinctive feature is the shape of the iron, which is double-pointed. Practically all the range sadirons in use today are pointed at the back as well as front for the proper handling of fancy articles. The Watson iron, however, is the only electric flatiron which does not have to go back to the old square end in order to accommodate a resistance unit. Owing to the nicety of adjustment possible in the size of the magnetic coil, these irons can be furnished accurately tested out for any circuit from 100 to 120 volts of any frequency. No harm, however, can result from subjecting them to an overload of fifteen per cent.

The handle, connections and finish are very durable and will retain their good appearance through considerable usage. The terminals are a special feature and are provided with a flexible cord so connected that it will not kink or wear. The terminal plug is easily slipped off or on to break or make connection directly back of the handle.

Hydraulic Turbine for Nelson, B. C.

The accompanying illustration shows a 1,250-horsepower hydraulic turbine in course of construction at the Scranton works of the Allis-Chalmers Company.



TWELVE-HUNDRED-AND-FIFTY-HORSEPOWER SINGLE TURBINE FOR THE CITY OF NELSON, B. C.

This turbine has now been installed at the power house of the city of Nelson, B. C.

The turbine and vertical alternator are both of Allis-Chalmers Company's standard design, and, after extensive tests in service, were found to be even more efficient than was claimed for them by the builders. The turbo-generator has a normal capacity of 750 kilowatts, but during the test run, at which the city officials of Nelson were present, this output was increased to 1,340 kilowatts for a period of over forty-five minutes' continuous running, without undue increase in temperature of bearings.

Up to the time of installing this unit the lighting and power loads for the city had been supplied by the West Kootenay Power and Light Company, situated just across the Kootenay River from the new city power plant, the river being the source from which both plants derive power.

The Industrial Instrument Company.

The Industrial Instrument Company was organized by men who have long been engaged in the manufacture of measuring instruments, the leaders being B. B. Bristol, E. H. Bristol and W. E. Goodyear, all of Waterbury, Conn., who were for many years active in the development of the Bristol Company.

The Messrs. Bristol, who were among the original incorporators of the Bristol Company, with several of their co-workers, withdrew from that company last spring, to develop a plan that involves the development of an extensive line of those types of measuring instruments and apparatus, the use of which promotes, directly or indirectly, safety and economy of operation in industrial plants, and oftentimes makes possible operations which, without such instruments or apparatus, would be impossible. It is proposed to concentrate all energies in the development and sale of a harmonious line of apparatus for this one broad economic field.

This plan presents many advantages from the customer's standpoint, in that he is able to secure a certain distinct class of apparatus from one house, knowing that the component parts will harmonize, and that he has obtained a well co-ordinated equipment designed to accomplish a certain result. He is relieved of the inconvenience of securing parts of an equipment from different makers and of the responsibility and forethought necessary to insure their successful operation as a whole.

From the vendor's standpoint, it is, of course, an advantage to have a certain class of customers, whose problems it is possible to study, so that their peculiar requirements in a certain direction may be met to a nicety.

Lastly, manufacturers' efficiency is attained through the use of the same equipment for the production of several closely related articles, rather than the employment of different equipment for each.

The Industrial Instrument Company is a Connecticut corporation, with authorized capital stock of $2,000,000. This company now owns the entire capital stock of the Standard Gauge Manufacturing Company, until recently of Syracuse, N. Y., and of the Standard Electric Time Company, of Waterbury, Conn.

The Standard Gauge Manufacturing Company will be reincorporated in Connecticut. It has purchased a plant at Foxboro, Mass., into which it has moved from its outgrown quarters at Syracuse. The personnel of the organization includes instrument engineers of long experience, so that its engineering staff is capable of meeting successfully demands for apparatus of a special nature for particular conditions, so long as it falls within the company's scope. This engineering staff will continually be engaged in the development of those types of instruments necessary to complete the line planned by it.

The sales end of the business will be carried on by the Industrial Instrument Company, of New York, which has recently been formed for this purpose. This company will handle the entire output of the Standard Gauge Manufacturing Company, and also the industrial branch of the business of the Standard Electric Time Company.

The officers are: President, Bennett B. Bristol, formerly secretary and treasurer of the Bristol Company; vice-president, Walter W. Patrick, until recently manager of the New York office of the Bristol

Company; secretary, Henry P. Dennis, formerly manager of the Chicago office of the Bristol Company; treasurer, Arthur F. Mundy, secretary and general manager of the Standard Gauge Manufacturing Company.

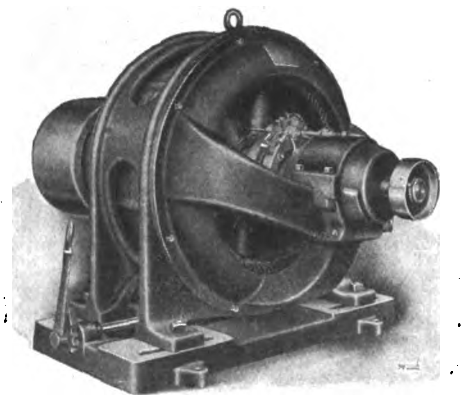
It is the intention of the company to place on the market instruments as fast as they can be perfected and developed to a point where they can be considered worthy of the confidence and support of the engineering world.

The home office will be located at Foxboro, Mass., with sales offices at 50 Church Street, Hudson Terminal, New York, and 752 Monadnock Building, Chicago.

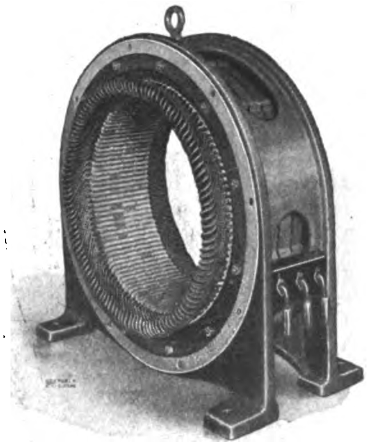
A New Line of Belt-Driven Alternators.

A new line of polyphase belt-driven alternators, known as Form PB, has been developed by the General Electric Company, Schenectady, N. Y., for use in small generating plants and in isolated lighting and power plants, where rapidly increasing inductive loads and consequently low power-factors are encountered. Designed for eighty per cent power-factor service, they will operate, however, with equal success on higher power-factor service.

The Form PB generators, shown in the accompanying illustrations, are arranged for belt drive, and are furnished with pulley and sub-base, the sub-base being provided with a ratchet screw or belt-tightening device. Although it is customary to supply these generators as belted units, they are readily adapted for direct connection to water-wheels by omitting the driving pulley and sub-base and adding a coupling. All generators have on the end opposite the driving end a shaft extension to receive the exciter driving pulley.



FORM PB BELT-DRIVEN ALTERNATOR.



STATOR WINDING AND FRAME.

The armature frame is of rugged construction, so proportioned as to give maximum strength and rigidity with a light and compact structure. Ventilating openings are provided, which allow a free circulation of air around the ends of the windings and through ducts in the laminated core. The armature coils are form-wound, thus allowing a damaged coil to be readily replaced, if necessary.

The field structure consists of laminated pole-pieces dovetailed into a laminated iron spider. The punchings are carefully stacked and riveted together, forming a rotor that will safely withstand high speeds.

Two methods of building the field coil for revolving-field machines are used. For the fifty-kilowatt and seventy-five-kilowatt sizes the wire is wound on spools, which are slipped over the pole-pieces and held in place by the enlarged pole-tips. In the larger sizes, the field coils consist of a single strip of flat copper wound on edge, so that one surface of every turn is exposed to the air. This construction permits thorough and efficient insulation between each turn and insures a low temperature in operation.

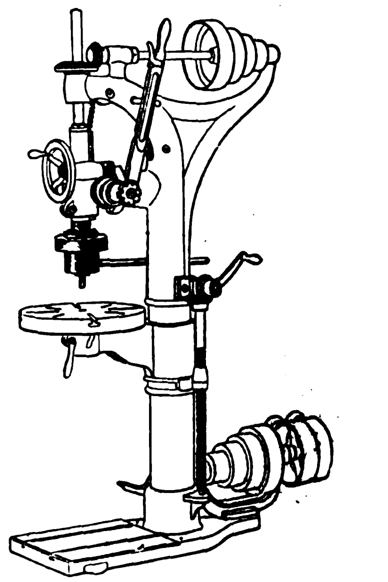
The collector rings for the field are mounted on insulating bushings, located on the shaft, and are exposed to the air on all sides. Two or more carbon brushes are provided for each ring, and no attention is required during operation.

As noted before, these generators have been especially designed for use in isolated plants where mixed lighting and motor loads are the rule rather than the exception. It is practically impossible in such cases to obtain good voltage regulation by hand control, and some form of automatic voltage regulator must be used. For this service the well-known TA regulator, manufactured by the General Electric Company, is recommended. When used in connection with the exciters for the PB alternators, this automatically maintains practically constant voltage at the bus-bars or at the center of distribution, according to adjustment. The exciters have a normal voltage of 125 volts, but are capable of delivering 150 volts continuously. This margin of power enables them to overcome easily the demagnetizing effect of the armature current on circuits of low power-factor.

When intended for operation as synchronous motors, Form PB generators are equipped with an amortisseur or squirrel-cage winding, located in the revolving-field pole-pieces, this winding giving ample starting torque with very low value of starting current. The winding does not in the least affect the operation of the machine as a generator. These generators are at present available with either two or three phase windings and for operation at 240, 480, 600, 1,150 and 2,300 volts. The overload ratings and temperature guarantees are conservative and in accordance with the best engineering practice.

A Triangular Bit for Boring Square Holes.

The problem of boring square holes, or holes of other shapes than round, has long attracted inventors, and is, moreover, of considerable practical interest in view of the wide use of such holes for counter-

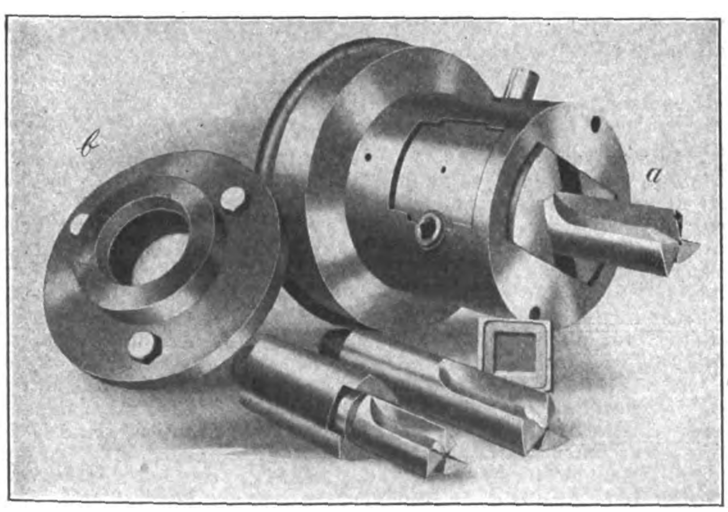


TRIANGULAR BIT AND GUIDES SET UP IN SINGLE-SPINDLE DRILL.

sinking and for keys, wrenches, spanners, hand-wheels, and similar articles. The present methods of making square holes (outside of punching and casting), such as first boring round holes and then working them up by hand or by means of a slotter or shaper, are laborious, expensive and slow.

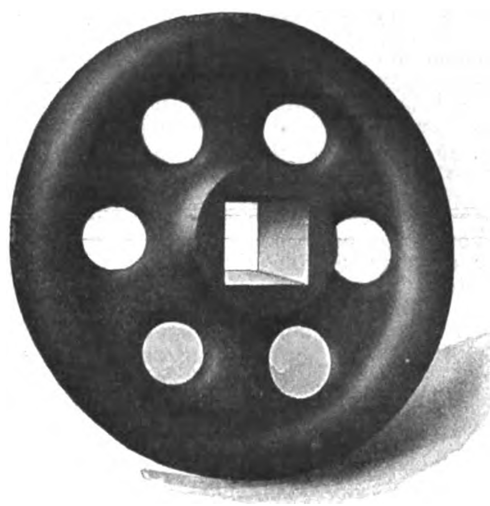
The machine to be described, however, bores square holes with the same facility and with nearly the same speed that the ordinary twist or flat drill will bore a round hole in the same material. At the same time the tool, while not altogether as simple as the flat drill, is not complicated nor expensive, and is easily made or ground in the average machine shop. The only appliance needed for the use of this special tool upon such machines as lathes, drill presses and milling machines, is a special chuck, which constitutes its principal interest from a mechanical standpoint, and which we shall now proceed to describe.

The chuck is really a device of making the three-cornered boring tool or bit travel about in such a way as to strike out a square hole in the work. It consists of a driving part, which is screwed onto the spindle of the machine, a guiding part, which either rides upon the first part, or else is secured permanently to the frame of the machine, and a third part, or socket, into which the shank of the drill is screwed. This third part is caused to rotate by the first part, but has a slight freedom of motion in relation thereto, being guided as to its exact movements by the matrix or frame in the stationary part. Where square holes are to be drilled, the shank of the tool is three-cornered, the sides of the shank being formed by segments of circles struck from opposite corners as centers, the radius of these circles being the same and equal to one of the sides of the square hole which is to be drilled. The guide in the stationary part of the chuck is adjusted to the size of the hole to be drilled, that is, so that the sides of the square opening are just equal to the radius by which the circles used for striking out the sides of the shank are formed.



TRIANGULAR BIT AND CHUCK.

In boring, when one of the sides of the shank is either rolling or sliding upon one of the sides of the square guide, the opposite corner of the shank will be moving in a straight line in contact with the opposite side of the guide. The corresponding corner of the head of the tool would at the same time strike out a straight line in the work. This motion takes place on all four sides of the guide, except for a little space at each corner,



NATURE OF CUT MADE WITH ANGULAR BIT.

the result being that the hole is perfectly square except for a slight rounding at the corners. If it is desired to bore out a complete square with sharp corners, a special tool is employed, having a shank considerably larger than the head of the tool, one corner of the shank being rounded instead of angular. The exact form of this round-cornered shank has been worked out empirically, and a complete set of templets made for the different sizes of tools apt to be required in actual practice. The tools for both the round - cornered and sharp - cornered squares can be ground by means of a special attachment to the ordinary grinding machine.

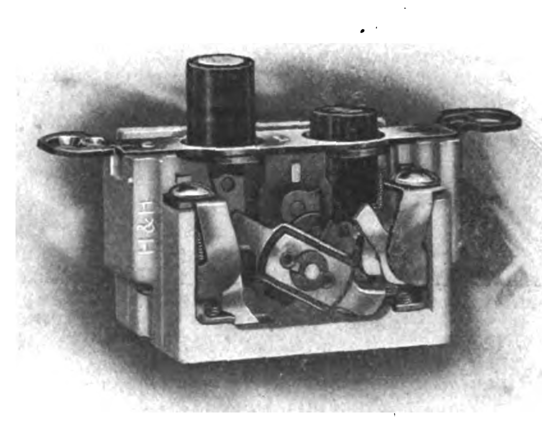
The accompanying illustrations show the arrangement of the special chuck for handling the triangular bit. As is clearly displayed in the first of these views the chuck can be inserted in the stock of a standard single-spindle drill.

This device has recently been put on the market in Germany, where a large number of chucks are in use in the shops of such firms as Friedrich Krupp, Siemens & Halske, etc. It is being introduced in this country by the Radical Angular Drill Company, having offices and showrooms at 114 Liberty Street, New York city, where the machine and samples of its work are now on exhibition.

The H. & H. Shallow Push-Switch.

The accompanying illustrations show the shallow push-switch which has been placed upon the market by the Hart & Hegeman Manufacturing Company, Hartford, Conn. This is made single-pole for ten and five amperes, 125 and 250 volts; in double-pole, ten amperes, 250 volts; in three-way, ten and five amperes, 125 and 250 volts, and in four-way, five and two amperes, 125 and 250 volts.

This shallow push-switch has been developed to meet the demand for a push-switch for shallow partitions, and in order to allow more room for wires in the regular box. Exhaustive tests on the new switch have been made, and the company is confident that the operation of this switch will substantiate its claims for excellence and fitness for the service intended.



H. & H. SHALLOW PUSH-SWITCH.

Current Electrical News

CONTINENTAL EUROPE.

(Special Correspondence.)

PARIS, DECEMBER 14.—Among the new companies which have been formed in France, I note the Gas and Electric Company, of Villeneuve, which has its headquarters at Paris; Costier et Cie., which is formed for the manufacture of lamp bulbs, also at Paris; Hamille et Cie., an accumulator manufacturing company, at Neuilly, in the suburbs of Paris, also the Compagnie de l'Energie Electrique de l'Aube, at Troyes, and the Société Electrique de la Barousse, which is located at Toulouse. A large company has been formed at Lille, France, known as the Compagnie Generale Boulonnaise d'Electricité.

The report of the Energie Electrique Company for the last fiscal year showed a prosperous state of affairs. This company owns the large system of hydraulic plants and network of power lines in the Mediterranean Alps region, which supplies current for Nice, Monte Carlo, Toulon and Marseilles. The report showed receipts $362,000, which is $47,000 above last year's showing, and expenses $157,000, or $18,000 in excess of last year. The profits for the year are, therefore, $205,000.

Among the recent electric-lighting and power projects in France it may be noted that the municipality of Sainte-Florine has received a proposition for a current supply to be taken from a central station located in the region at Lenyts. The municipality of Nuits-St. Georges will probably adopt an electric-lighting project, which has been presented to it by M. Sarazin. A new company has been formed in the town of Buironfosse, Alsace, in order to secure a power supply for this locality and others in the same region. At Onnaing the rights for the electric-lighting supply have been obtained by M. Vinker.

The main work of the recent telegraphic congress held at Lisbon has been the revision of the international telegraphic regulations, which form part of the St. Petersburg telegraph convention. There has been recently published the revised text of the telegraph regulations, together with the international rates, both European and extra-European, also the present rates of the different cable companies.

The Industrial Society of Mulhausen, Alsace, is to award a number of medals and other prizes for its annual concourse of next year. One of the points relates to a new type of boiler, which must have been in regular working in Alsace for one year past. There is also a medal awarded for a self-stoking boiler, which uses the fuel prevailing in the country. A prize is to be given for a totalizing indicator of the work of a steam engine, also for a producer or blast-furnace gas engine, of at least 250 horsepower, which has advantages over a steam engine. Among the other subjects are a gas producer, an improved smoke consumer, and a mechanical conveyor for furnace slag.

Among the new radio-telegraphic stations may be noted the connection which has lately been opened up between Zanzibar and the Pemba Island.

It is stated that the Siemens-Schuckert electric firm of Germany will go into the manufacture of airships, and is to erect a large factory for this purpose at Nauen. A. DE C.

GREAT BRITAIN.

(Special Correspondence.)

LONDON, DECEMBER 12.—The Post Office authorities have granted licenses for the erection of a number of exchanges in connection with the employment of what is now called the "telewriter," or more familiarly Ritchie's telautograph, which was brought to the public notice here some years ago. The appliance operates to reproduce writing or drawings directly, in the same way that messages can be sent over the telephone. The apparatus has already a fair use in business houses and the idea is to set up exchanges and canvass for subscribers precisely on the lines of a telephone business, royalties being paid to the government for the facilities thus afforded and for the necessary wayleaves.

The Board of Trade has caused a little stir in municipal circles in Bath by prohibiting the sale of the local electrical undertaking to a private company. Curiously enough the Bath undertaking was originally commenced by a company and was purchased by the municipality. Now the latter cannot make it pay and has proposed to transfer it to another company in perpetuity, at a price some $200,000 above the cost to the city. To this, the Board of Trade has refused to consent, holding that it is improper that the undertaking should be burdened with the extra price for a plant which is already eleven years old. It also appears that under the Electric Lighting Acts a local authority cannot lease its electrical powers in perpetuity.

When both the Light Railways and Tramways Association and the Municipal Tramways Association appointed committees to investigate the brake question, the Board of Trade endeavored to bring about a fusion of the two committees and thus avoid the preparation and publication of two reports on the same subject. The two bodies, however, could not come to an agreement and so the investigations went on independently, there being at the same time a little friction, with the result that certain members of the former body resigned. The Tramways and Light Railways Association issued its report a short while ago, and it was duly noted at the time. The second report has now been issued and it arrives at more or less the same conclusions. The chief point, however, is the emphasis placed upon the need for keeping the rails clear of grease. The committee reports in favor of a brake which can be applied either by hand or power by a single lever to both rails and wheels, and reports against having a brake purely for emergency purposes. G.

(Special Correspondence.)

OTTAWA, DECEMBER 19.—At a meeting of the City Council of Windsor, Ont., for further consideration of the Niagara power scheme of the local government, 1,200 horsepower was fixed on as the amount that the city will be able to use.

The City Council of Brantford, Ont., has asked the Street Railway Company to put up a guarantee of $25,000 that the present lines will be rebuilt within one year and an extension made within two years, before a renewal of the franchise will be granted. The company's rights have lapsed owing to failure to make the improvements as promised by the company.

The Ontario Power Company, of Niagara Falls, is preparing plans for the construction of a new pipe line to increase its capacity of electric power by 65,000 horsepower. The work will be commenced early in the coming spring. This work is made necessary in order to handle the contract with the Hydro-Electric Commission of Ontario. The tunnel will be of steel, lined with concrete, and will be thirty feet in diameter and upward of one mile in length. The work will cost about $750,000 and when completed the company will be able to develop 180,000 horsepower.

A conference of the municipalities of the southwestern peninsula of Ontario was recently held at Windsor to hear Hon. Adam Beck, chairman of the Hydro-Electric Commission, explain the government's Niagara power scheme. At least seventeen municipalities will vote on the electric power by-law on January 4. With the taking of 5,000 horsepower, or more, an estimate was given at $34.90 per horsepower. W.

WESTERN CANADA.

(Special Correspondence.)

WINNIPEG, DECEMBER 19.—The City Council of Edmonton, Alberta, has decided to double the equipment of the municipal street-railway system which operates in Edmonton and the sister city of Strathcona. So far the system has proved a very great success and it is apparent the venture will be as profitable financially as the other public utilities owned by the city.

At the recent municipal elections held in Winnipeg two of the candidates were pledged for the immediate completion of the civic power plant at Point du Bois; the third candidate was opposed to the civic power development, one of the planks of his platform calling for the abandonment of the scheme and favoring the purchase of power from the Winnipeg Electric Company. Approximately 11,000 votes were cast for the three candidates, the anti-power man getting but 129 of that number. W. Sanford Evans was elected over R. A. C. Manning, the other pro-power candidate. The result of the election assures the early completion of the plant, for which tenders are now being called.

The Regina Interurban Tramway Company is the name of a new company seeking incorporation under the laws of the Province of Saskatchewan for the purpose of building electric car lines from Regina to adjacent towns.

At the coming municipal elections at Port Arthur, Ont., the rate-payers will vote on a plebiscite to decide whether the electrical interests owned by the city shall continue in charge of the commissioners or whether an independent board of experts, removed from ward influences, shall be appointed. Among other public utilities the city operates the electric-lighting plant, telephone system and that portion of the street-railway system running in the city limits. J. J. Carrick is mayor.

At the next meeting of the City Council of Calgary, Alberta, Alderman Watson will introduce a motion providing for a sufficient sum of money being set aside for preliminary surveys and estimates for the proposed development of civic power at some site near Galgary, which is yet to be selected.

R. H. Sperling, general superintendent of the British Columbia Electric Street Railroad Company, with headquarters at Vancouver, British Columbia, announces the company is willing to build a line through the municipality of Port Grey providing the company can make a satisfactory arrangement with the authorities.

An official of the Canadian Pacific Railroad Company denies the reports published in a number of daily papers to the effect that the company will at once arrange for the electrification of certain lines in southern British Columbia. He admits the company is always ready to consider any proposition for the reduction of operation expenses, but says the electrification scheme for British Columbia has not been given serious thought as yet.

The Sunny Hill Rural Telephone Company has been incorporated under the laws of Saskatchewan to build a rural telephone system. Address E. J. Wright, Regina, Saskatchewan.

At Dundurn, Saskatchewan, the Dundurn Rural Telephone Company has been incorporated to build several farmers' telephone lines.

The municipal authorities at Birtle, Man., have ordered the instruments for a telephone system and a line is now being built to Solsgirth. Farmers living en route will be connected with the telephone system if they so desire. Address T. W. Thompson.

A company is being formed at Estevan, Sask., to build a telephone line to the Hamar and Ambrose districts. Address H. Yardley, Estevan.

Efforts are being made at Killam, Alb., to organize a company to build a telephone line to the farming districts to the south of that town. Address J. A. Neely, at Killam.

The $350,000 capital of the Regina Interurban Tramway Company, now seeking incorporation with head office at Regina, Sask., has already been subscribed. The company proposes to build a line from Regina to Long Lake and from that point to circle the city. The incorporators are: J. L. R. Parsons, R. R. Barber, C. J. Harris, W. M. Logan, J. F. Frame and J. H. Housser. R.

IMPORTANT DEVELOPMENTS.

(Special Correspondence.)

PENNSYLVANIA PREPARES FOR MAIN LINE ELECTRIFICATION—Estimates for about $5,000,000 of work along the main line of the Pennsylvania have been asked. The contract to be let will include damming the Juniata River, cutting away part of the mountain to eliminate a big curve and grade and erecting an immense power plant near Lewistown. That this is the first step by the Pennsylvania toward the electrification of the main line is believed generally.

NORTHERN PACIFIC CONSIDERS ELECTRIFICATION OF MOUNTAIN SECTION—Engineers representing the motor-power department of the Northern Pacific Railroad have been in Livingston, Mont., working on a plan to use electricity in carrying trains over the mountains just west of the city. It is stated that the proposition is being investigated and that at an early day electric power is likely to be used in pulling both passenger and freight trains over the mountains. If the plan is adopted the company will construct a large power plant at some point on the Yellowstone River.

ILLINOIS TUNNEL COMPANY WOULD SELL ITS TELEPHONE FRANCHISE TO CHICAGO TELEPHONE COMPANY—Representatives of the Illinois Tunnel Company, which operates the freight tunnels under the city of Chicago and also controls a telephone franchise, serving buildings reached by its tunnels with an automatic telephone service, have appeared before the City Council asking permission to sell its telephone franchise and plant to the Chicago Telephone Company. In accordance with the terms of its contract with the city, the tunnel company will lose its franchise February 8 unless the 20,000 telephones stipulated are installed by that time. Its present subscribers do not total more than one-quarter of this number. The members of the Council have not been disposed to decide upon giving the permission offhand, and have taken the matter under consideration. If, as the Independent telephone interests hope, they are successful in getting into Chicago for toll-line connections or for a city exchange, the present lines of the tunnel company could be used by them to good advantage.

OBITUARY.

MR. C. A. DERTSLER, engineer for the British Columbia Electric Street Railroad Company, was drowned while crossing the Vedder River near Chilliwac, B. C., on a raft. The raft struck a rock in mid-stream and was dashed to pieces. R.

NEW MANUFACTURING COMPANIES.

RACINE, WIS.—The Racine Electrical Manufacturing Company has been incorporated with a capital stock of $25,000.

DENVER, COLO.—The capital stock of the Silver State Electric Company has been filed at $50,000. The incorporators are R. S. Willoughby and M. T. Weber of Denver.

PORTLAND, ME.—The Pemigewasset Electric Company of Portland, general electrical merchandise dealers, has been capitalized at $150,000 by A. G. McPhierson, J. R. Parsons and W. M. Bradley.

FORT SMITH, ARK.—The Pittsburg Supply Company has been incorporated with a capital stock of $50,000 by E. C. Lichty, J. B. Weatherton and P. C. Hendricks, to manufacture electrical supplies and fixtures.

CHICAGO, ILL.—The Electromagnetic Tool Company, organized with a capital of $50,000, has been incorporated by O. R. Barnett, P. H. Truman and L. H. Peck, to manufacture electrical and electromechanical devices.

NEW YORK, N. Y.—The Hardt Electric Company, Manhattan, incorporated for the purpose of manufacturing electrical appliances, with a capital of $50,000, has been formed by R. M. Patterson, G. Link, Jr., and C. Rush, New York city.

NEW YORK, N. Y.—The Monarch Storage Battery Company, of New York city, has been incorporated with a capital stock of $50,000 to manufacture electrical and mechanical appliances. The incorporators are headed by Alexander D. Thornburn, of New York.

CHICAGO, ILL.—The Chicago Engineering and Inspection Company has been incorporated with a capital stock of $2,500 to do a general engineering, electrical and construction business. G. M. Proudfoot, A. R. Leland and J. H. Westover are members of the company.

BROOKLYN, N. Y.—The Borough Gas and Electric Fixture Company, of Brooklyn, has been chartered with a capital of $25,000. The directors are: S. J. Miller, Jennie Miller, A. B. Cohen, Louis Halpert, George Bauer, Hyman Kagel and Bernard Rathberg, of Brooklyn.

BOSTON, MASS.—The National Electric Manufacturing Company of Boston has been incorporated to manufacture and sell electrical apparatus. Its capital is placed at $50,000 and its officers are: President. Starbuck Sprague, No. 21 Bromfield Street; treasurer and clerk, Charles H. Sprague, No. 15 Beacon Street.

DULUTH, MINN.—The Richardson Electric Company has been organized under the revised laws of 1905 of Minnesota, to buy, sell, manufacture, install and deal in electrical apparatus, appliances, machinery, fixtures and supplies of every kind, and to engage in all branches of electrical engineering and construction work for light, heat, power and all other purposes, and to manufacture, purchase, supply, sell and deal in electricity and electric power; also to engage in the manufacture, engineering, construction and equipment of telephone, telegraph, heating, lighting, plumbing, ventilating, electrical and mechanical systems. The incorporators are William P. Bear, Frank Windblade, Axel W. Lindgren, Walter L. Seaton, all of Duluth. The first board of directors is as follows: William P. Bear, president; Frank Windblade, secretary and treasurer; Axel W. Lindgren, vice-president. The capital stock is $50,000, divided into 1,000 shares of $50 each.

NEW PUBLICATIONS.

THE MINNESOTA ENGINEER—The November issue of the quarterly published by the Engineers' Society of the University of Minnesota contains a detailed description of the Hatfield hydroelectric plant of the La Crosse (Wis.) Water Power Company, by Albert J. Hitzker, a senior in the school of electrical engineering.

NAVY DEPARTMENT ANNUALS—The following publications for the fiscal year 1908 have been received from the Navy Department Library: Annual report of the Superintendent of Library and Naval War Records to the Secretary of the Navy; annual report of the Chief of the Bureau of Equipment; annual report of the Chief of the Bureau of Yards and Docks; annual report of the Chief of the Bureau of Ordnance.

CHEMICAL ANALYSES OF COAL—In behalf of the United States Government, which is a large user of coal, the United States Geological Survey in 1907 made a thorough investigation of the Pocahontas and New River coals. The tests were conducted at the Government plant on the grounds of the Jamestown Exposition, near Norfolk, Va., and their especial purpose was to determine the best methods of using the coals economically. The results of these tests are published as Bulletin 362 of the United States Geological Survey, in a pamphlet by John Shober Burrows, entitled "Mine Sampling and Chemical Analyses of Coals Tested at the United States Fuel-Testing Plant, Norfolk, Va., in 1907."

ELECTRICAL SECURITIES.

Generally downward price movements, with an irregular market, were the prevailing speculative and investment conditions last week. Not since election has there been heard so much complaint of the recent advance in prices having discounted growing improvement in trade. The necessity of meeting large end-of-the-year disbursements has caused some anxiety and this has probably had a considerably depressing effect upon optimism. Railroads continue to report improving returns with advances in net well sustained.

Dividends have been declared upon the following electrical securities: Electric Storage Battery Company; regular quarterly dividends of three-fourths of one per cent on the common stock and three-fourths of one per cent on the preferred stock, payable January 2 to stock of record December 23. Cincinnati Gas and Electric Company; regular quarterly dividend of one-and-one-eighth per cent, payable January 1. Cincinnati Street Railway Company; regular quarterly dividend of one-and-one-half per cent, payable January 1. Nebraska Telephone Company; regular quarterly dividend of one-and-one-half per cent, payable January 10 to stock of record December 31. Cumberland Telephone and Telegraph Company; regular quarterly dividend of two per cent, payable January 1 to stock of record December 20. Bell Telephone Company of Canada; regular quarterly dividend of two per cent, payable January 15 to stock of record December 24. American Telephone and Telegraph Company; regular quarterly dividend of two per cent, payable January 15 to stock of record December 31. Tri-City Railway and Light Company; regular quarterly dividend of oneand-one-half per cent on the preferred stock, payable January 2 to stock of record December 22. American Cities Railway and Light Company; regular quarterly dividend of one-and-one-half per cent on the preferred stock, payable January 1 to stock of record December 21. Massachusetts Lighting Companies; regular quarterly dvidend of one-and-one-half per cent, payable January 15 to stock of record January 1. Boston and Worcester Electric Companies; $1 per share on the preferred stock, payable January 1 to stock of record December 26. Capitol Traction Company; quarterly dividend of one-and-one-half per cent, payable January 1. Continental Passenger Railway; semi-annual dividend of $3, payable December 30. Germantown Passenger Railway; quarterly dividend of $1.31¼, payable January 5. Honolulu Rapid Transit and Land Company; quarterly dividend of one per cent on the common and three per cent on the preferred, both payable December 31. Manila Electric Railroad and Light Company; quarterly dividend of one per cent, payable December 31. Massachusetts Electric Companies; preferred stock dividend of $1, payable January 1. Philadelphia Company; quarterly dividend of one-and-one-half per cent, payable February 1 to holders of record January 2. Rochester Railway Company; quarterly dividend of one-and-one-fourth per cent, payable December 31. Stark Electric Railroad; quarterly dividend of three-fourths of one per cent, payable January 1. Toronto Railway Company; quarterly dividend of one-and-one-half per cent, payable January 2.

ELECTRICAL SECURITIES FOR THE WEEK ENDED DECEMBER 12.

New York and New Jersey Telephone	110
Western Union (ex-dividend)	66⅞
Westinghouse Manufacturing Company	86

At a special meeting of the Edison Electric Illuminating Company of Boston, held December 18, stockholders voted to increase the capital from 126,436 to 136,161 shares. This new issue of 9,725 shares will be offered to stockholders of record December 18 for subscription at $215 a share—the price determined by the Massachusetts Gas Commission—on the basis of one new share for each thirteen shares now held. Subscription books close January 15 and subscriptions are payable as follows: One hundred dollars on February 1 and $115 on May 3, 1909. Subscriptions for the new shares of the Edison Company of Boston will be received at the Old Colony Trust Company. Interest at the rate of four per cent per annum will be allowed on the first installment ($100 per share) from February 1 to May 1, 1909. Subscribers may prepay the second installment ($115 per share) on February 1, 1909, in which case interest will be allowed thereon at the rate of four per cent per annum from February 1 to May 1, 1909. Shares not subscribed for will be sold at auction.

For the last month gross earnings of the Brooklyn Rapid Transit have shown a decided improvement over the corresponding days last year. Since December 1 this increase has been running at the rate of $1,000 a day.

For the first three months of the current fiscal year, which began July 1, gross earnings showed a sharp falling off, compared with the same quarter of 1907, the decrease slightly exceeding six per cent. It was not until November 1 that earnings began to break even with last year, and only within three weeks that a noticeable gain has been shown.

It is probable that for the six months, to end the last of this month, the company will show a decrease in gross of about four per cent.

Like many other trolley systems, however, Brooklyn Rapid Transit has been remarkably successful in cutting down its operating expenses during the last six months. The economies effected have been strictly legitimate and have in nowise resulted in scaling down the standard of maintenance. As a result net earnings are on a practical parity with last year.

It is understood that the floating debt of $4,000,000 on June 30, the close of the fiscal year, has been cut down over $1,000,000, and there is a strong probability that it will be cut nearly $2,000,000 more by the close of the fiscal year. The company is in no need of financing and is able to take care of its current construction requirements out of net earnings.

TELEPHONE AND TELEGRAPH.

(Special Correspondence.)

SABIN, WIS.—The Mill Creek Telephone Company has been incorporated.

HURON, S. D.—F. H. Kent and others have secured a telephone franchise at Huron.

BELLO, TEX.—The Bello Telephone Company has been incorporated by Charles Wild and others.

DISNEY, NEB.—The Spring Ranch Telephone Company has been incorporated with a capital of $5,000.

KALISPELL, MONT.—The farmers near Kalispell are making an effort to have a local telephone system. C.

ESSEX, IOWA—The Farmers' Telephone Company has been incorporated with a capital stock of $15,000.

NEOSHO, MO.—The Farmers' Union Telephone Company has been incorporated by J. B. Graves and others. P.

ADA, OKLA.—The Farmers' Independent Telephone Company has been granted a telephone franchise for Ada.

LADORA, IOWA—The Farmers' Mutual Telephone Company has been incorporated with a capital of $20,000.

CARNEGIE, OKLA.—The Carnegie Telephone Company has been incorporated with a capital stock of $10,000.

LEBANON, WIS.—The Lebanon Telephone Company has been incorporated with a capital stock of $10,000.

LADORA, IOWA—The Farmers' Mutual Telephone Company has been incorporated with a capital stock of $20,000.

IPSWICH, S. D.—The Union Township Telephone Company has been incorporated with a capital stock of $10,000.

NEW KENT, VA.—A company with a capital stock of $5,000 has been formed to build a telephone system in New Kent.

CLARINDA, IOWA—The Clarinda and Bethesda Telephone Company has been incorporated with a capital stock of $1,000.

MARSHALLTOWN, IOWA—The Farmers' and Merchants' Telephone Company has been incorporated with a capital stock of $250,000.

COOPERTON, OKLA.—The New State Telephone Company has been incorporated with a capital stock of $25,000 by W. C. Winnsworth and others. P.

ELECTRIC RAILWAYS.

(Special Correspondence.)

SEATTLE, WASH.—W. S. Boody and others have applied for a subway street-railway franchise in Seattle.

GUADALAJARA, MEXICO—The Compania de Tranvias, Luz y Fuerza of Guadalajara, has increased its capital stock from $3,000,000 to $8,500,000. Andres Bermejillo is president. D.

TORREON, MEXICO—The new electric power plant which the Lerdo & Torreon Electric Railway Company is erecting at a cost of $400,000 will soon be finished. The company will also make other extensive improvements. D.

ORIZABA, MEXICO—The Compania Empresa Electrica will, it is reported, expend $300,000 in the construction of a system of electric railways at Orizaba. The company was recently organized and is composed of local capitalists. D.

BUCK, ILL.—The Egyptian Steam and Electric Railway Company of Buck has been incorporated to construct and operate a railway from East St. Louis to Metropolis, Ill. The capital stock is $5,000 and John Edmonds is one of the incorporators.

TACOMA, WASH.—The Cle Elum-Roslyn Railway and Power Company of Cle Elum, incorporated by Frank S. Farquahar and W. E. Farquahar, with a capital stock of $100,000, will construct and operate an electric interurban railway between Roslyn and Cle Elum.

MEXICO CITY, MEXICO—The Mexico Tramways Company has been authorized by the Federal Government to convert its existing mule-car lines to electric traction and operate them as part of ts local electric-railway system. The improvements will be made immediately. D.

BAYONNE, N. J.—Civic organizations of Staten Island and Bayonne are considering a rapid transit scheme whereby it is proposed to construct a surface electric line from Perth Amboy to Port Richmond, then to tunnel the Kill von Kull to the Jersey Central Station in Bayonne, and eventually reach Manhattan by the Hudson River tunnel.

HERMOSILLO, MEXICO—It is reported that the branch line of the Sonora Railroad, which runs from La Union to Hermosillo, is to be sold to a local company and that it will be converted to electric traction. Negotiations have not yet progressed to a point when a definite announcement of the sale of the road can be made, but it is said that there is little doubt that the transaction will be consummated. The branch line runs up the canyon of the Sonora River and is said to be unprofitable as now operated. D.

LANCASTER, PA.—The property of the Philadelphia, Coatesville & Lancaster Electric Railway Company, which has defaulted payment on the interest of its first mortgage bonds for $600,000, recently due, will be sold on December 30. It is understood that this is a step in the acquirement of the franchise by the Conestoga Traction Company, which operates the trolley system of Lancaster County, and that as soon as it gets a title to it it will extend its Christiana line through to Parkersburg, to connect with the line to Philadelphia.

LITTLE ROCK, ARK.—A charter has been granted to the Helena, Parkin and Northern Railway Company, which proposes to build a line of railway, fifty miles in length, through St. Francis, Cross and Poinsett counties. The line begins at Whitmore, in St. Francis County, and extends to Marked Tree, in Poinsett County. The capital stock of the company is $350,000, of which amount $100,000 has been subscribed. It is reported that everything is in readiness to begin work at once. The incorporators are headed by T. E. Hare.

MEXICO CITY, MEXICO—The Arizona Mercantile Transportation and Smelter Company, which operates mines and smelters at Silver Reef, Ariz., has taken preliminary steps to obtain a concession from the Mexican government for building a railroad across a section of Mexican territory to reach St. George's Bay, a proposed deep-water harbor situated in the extreme upper end of the Gulf of California. The project is an ambitious one and contemplates the building of an electric railway 160 miles long, to run from Maricopa, Ariz., across the lower part of that territory and into Mexico to the prospective deep-water terminus. The company's plans also include the establishment of extensive port facilities at St. George's Bay, making it the outlet for the export traffic of a large section of the Southwest. D.

GUADALAJARA, MEXICO—The preliminary survey for the proposed electric railway which the Soledad Development Company is to build to the Mezquital del Oro mining district, in the state of Zacatecas, is nearly finished, and it is declared by the promoters of the enterprise that the construction of the line will soon begin. Application has been made to the government of the state of Jalisco for a concession for that part of the line that is to run through that state, and similar application will be made to the government of the state of Zacatecas for the remaining portion. The line will be about seventy-five miles long and will traverse a territory that is thickly populated. A hydroelectric plant will be installed on the Santiago River, and power for the line will be obtained from that source. The particular object of the proposed road is to afford a transportation outlet for the Mezquital del Oro mining district. D.

MEXICO CITY, MEXICO—It was given out by Dr. F. S. Pearson, president of the Mexico Tramways Company, on the occasion of his recent visit, that a general programme of improvements for the local system of electric street railway has been discussed with the government officials and arrangements completed to expend, within the next three years, about $5,000,000 gold. This sum is to be used principally in the construction of new lines in different parts of the city and in adding equipment for both passenger and freight service. D.

PERSONAL MENTION.

MR. A. B. DU PONT, former president of the Municipal Street Railway Company of Cleveland, O., has been retained by the company as consulting electrical engineer.

MR. A. G. PERRY has been appointed manager at North Vancouver, B. C., for the British Columbia Electric Street Railroad Company in place of W. B. Bunbury, who has resigned. R.

MR. WALTER E. HOLLOWAY, after twenty years' service with the Safety Insulated Wire and Cable Company, of New York city, will leave the position of general purchasing agent for the company, January 1, to enter into business for himself.

MR. W. R. BONHAM has been appointed sales manager for Cook County, Illinois, for the Electro-Dynamic Company, Bayonne, N. J., representing this company's full line of special and standard inter-pole motors. Mr. Bonham's headquarters are in the Monadnock Building, Chicago.

MR. HERBERT E. STONE has just become connected with the Dearborn Drug and Chemical Works as manager of sales in the eastern department, with headquarters in New York city. Mr. Stone was formerly president of the N. A. S. E., and recently manager of the Pittsburg office of the Chapman Valve Company.

MR. S. M. MANIFOLD, York, Pa., has removed to Morristown, N. J., accepting a position as general manager of the Morris County Traction Company, which connects the cities of Morristown, New Brunswick, Elizabeth and Orange. Mr. Manifold is a well-known and able railway man and was at one time general manager of the York Railways Company. O.

MR. W. D'A. RYAN, illuminating engineer for the General Electric Company, delivered a lecture on "Light and Illumination" on December 11 at the Memorial Hall, Minneapolis, Minn., under the auspices of the Minneapolis Electric Club. His address treated of illumination in general, describing and illustrating in particular the color values of the different illuminants and the effects of wall colorings.

MR. WILSON S. HOWELL, general manager of the Electrical Testing Laboratories of New York city, was a recent visitor to Chicago, in conference with the many interests with which this progressive enterprise is identified. So greatly has the work of the laboratories been extended, the value of scientific testing being conceded, that the possibility of further extension is being considered by those in charge of the work.

MR. FRANK J. DUFFY, manager of the Beaumont (Texas) Traction Company for several years, will leave Beaumont to make his headquarters in Natchez, Miss. The Natchez Street railway and lighting plant, the Jennings, La., lighting plant and the Beaumont Street railway are all under the same control, and Mr. Duffy will have general supervision over the Beaumont property in the future, but will resign active management. Mr. M. B. Rhoads of Key West, Fla., will succeed Mr. Duffy at Beaumont.

MR. KINGSLEY L. MARTIN, of Brooklyn, N. Y., has been appointed chief engineer of the Bridge Department of New York city, in place of Colin M. Ingersoll, resigned. Mr. Martin's salary will be $10,000 a year. At the request of Mayor McClellan and Bridge Commissioner Stevenson, Mr. Ingersoll has agreed to remain with the Bridge Department in the capacity of consulting engineer. Mr. Martin was selected for the position of chief engineer because of the record he has made as engineer in charge of the Brooklyn and Williamsburg Bridges. He was born in Brooklyn in 1869, and is a son of C. C. Martin, formerly chief engineer and superintendent of the Brooklyn Bridge. He was educated in the Polytechnic Institute, of Brooklyn, and was graduated with the degree of M. E. from Stevens Institute of Technology. After serving for a short time on the engineering corps of the East River Bridge Company, Mr. Martin was appointed assistant engineer of the Brooklyn Bridge. He had charge of terminal reconstruction on the Brooklyn side, and of much of the railroad work, the local road at that time being operated by the city. He was made assistant engineer on the Williamsburg Bridge in 1896, and was connected with the Manhattan foundation and anchorage work. He was later appointed resident engineer in charge of construction work, including all the mill, shop and field work.

ELECTRIC LIGHTING.

(Special Correspondence.)

ALVIN, TEX.—E. B. Hill has secured a twenty-five-year electric-light franchise at Alvin.

MACON, GA.—The city is considering the erection of an electric-light plant in Vineville.

TENAHA, TEX.—Lemuel Hill has been granted a franchise for installing an electric-light plant.

VILLISCA, IOWA—F. P. Tyler has been granted an electric-light and power franchise at Villisca. P.

RYAN, OKLA.—A vote is to be taken on the issuance of bonds for an electric-light plant for Ryan.

DANVILLE, ARK.—The Danville Electric Company has been incorporated with a capital stock of $10,000.

TACOMA, WASH.—On December 26 Tacoma will vote on a proposition to issue bonds for a power plant. P.

MINCO, OKLA.—The city of Minco will vote on the issuance of bonds for the construction of an electric-light plant.

KEARNEY, NEB.—The Kearney Water and Electric Power Company has been incorporated with a capital stock of $310,000.

BERGEN, N. Y.—At a village election held in Bergen it was decided to issue bonds for $6,000 for an electric-lighting system.

EMPORIA, KAN.—The Emporia Electrical and Gas Lighting Company has been incorporated with a capital stock of $100,000. P.

KEARNEY, NEB.—The Kearney Water and Electric Power Company has been incorporated with a capital stock of $310,000. P.

NASHVILLE, ARK.—J. C. Stephenson has a contract for furnishing Nashville with electric light, and a plant will be installed at once. P.

ELBERTON, GA.—The city is considering improvements to its electric-light plant, including raising of dam and installation of larger dynamo.

EUFAULA, OKLA.—The pioneer Electric and Power Company has been incorporated with a capital of $9,500, by C. E. Foley and others.

WORDEN, ILL.—A special election was held in Worden to vote on the issuance of $12,000 in bonds to build a municipal electric-light plant.

MT. AYR, IOWA—The town of Mt. Ayr is the last county seat of Iowa to install electric lights. A $20,000 power plant is now nearing completion.

FARWELL, MICH.—The election on the proposition to bond the village for $3,000 for the erection of an electric-light plant carried by sixty-two to nineteen votes.

LOS ANGELES, CAL.—The Burrows Wave Power and Electric Company has been organized with a capital of $75,000, by E. E. Beazley, H. C. Scheurer and John H. Forsythe.

BRUCE, WIS.—The new $15,000 municipal hydroelectric plant built for the town of Bruce by the Central Construction Company of Oshkosh has been successfully started up.

LEESVILLE, S. C.—The Brodie Light and Power Company has been incorporated with $10,000 capital stock by Furman E. Brodie and Claudia E. Brodie, both of Leesville, and C. P. Quattlebaum, Conway, S. C.

NORCROSS, GA.—The city is having specifications prepared for an electric-light plant and will want bids on machinery. Five thousand dollars in bonds was recently reported voted. T. E. Johnson is mayor.

CARMI, ILL.—The plant of the Olney Electric Light and Power Company has burned, leaving the city in darkness for at least a month. The loss is $24,000, with $17,000 insurance. The cause of the fire is unknown.

MARINETTE, WIS.—The Iron Mountain Electric Light Company has taken action to purchase the Twin Falls waterpower plant on the Menominee River. It will be developed at a cost of $50,000 and the power will be transmitted to Iron Mountain to light that city.

MARENGO, ILL.—Fred A. Rispen, who held the lease and management of the city electric-light plant for a term of years, has made an assignment, declaring that its operation was a losing undertaking. Following his affidavit he was appointed to manage the plant for the city for a time.

LYNCHBURG, VA.—Virginia and Northern capitalists propose the organization of a company, probably capitalized at $1,000,000, to build a waterpower electric plant on Staunton River, twenty-five miles south of Lynchburg. The plan includes the construction of a concrete dam costing $350,000 and the transmission of electricity to Lynchburg and other cities.

CHARLOTTE, N. C.—B. H. Hardaway of Columbus, Ga., has been awarded the contract by the Southern Power Company, a $10,000,000 concern of Charlotte, to build a dam across Broad River at Ninety-nine Islands, S. C., for a 16,000-horsepower electrical plant. The contract price was $650,000. This dam will be the largest structure of its kind in the South.

KILBOURN, WIS.—The Southern Wisconsin Power Company has agreed to give the village 133 horsepower free of charge for twelve hours each day, for all time, to move the village plant to higher ground or fill where it now stands, to install pumps of sufficient capacity and connect the mains. This will, it is believed, end the fight between the company and the village.

JEFFERSON COUNTY, W. VA.—Fred H. Stith of Lexington, N. C., plans the organization of corporation to develop waterpower and build electric plant for transmitting by electricity a minimum of 1,000 horsepower from property on the Potomac River in Jefferson County. Surveys are now being made. About $300,000 is to be expended and the establishment of Portland cement plant is also proposed.

LEGAL NOTES.

Conducted by J. L. Rosenberger, LL.B.

ELECTRIC-LIGHT STATION A MANUFACTORY—Is or is not an electric-light station, with the usual equipment of boilers, engines, and dynamos, a manufactory, within the meaning of a restrictive covenant and "scheme" intended to exclude manufactories from a residence district? This was the important question in the case of Scrymser vs. Seabright Electric Light Company, 70 Atlantic Reporter, 977. In deciding it, the Court of Chancery of New Jersey says that, in its judgment, it is useless to go into speculative questions as to the nature of electricity or the nature of the product, if there be a product, of the electric plant in question. At different periods in the history of electrical discovery very different views have been entertained on this subject. At one time this plant might have been regarded as a manufactory of a "fluid." More recently it might be deemed to be turning out electrons or ions. This electric-light station, with the necessary incidents attending its operation, is, in the court's judgment, as clearly a manufactory, within the meaning of this protective covenant, as it is a manufactory within the meaning of the mechanic's lien law. It may be conceded that when this particular covenant was framed and building "scheme" was promulgated, about thirty-five years ago, the "manufacture" of electricity in electric-light stations was unknown. But in view of the annoyance and discomforts which it was the intention of the scheme to exclude from the large residential district in question, no distinction can be drawn between manufacturing businesses which were in existence when the scheme was promulgated, and manufacturing businesses which might thereafter come into existence.

DEMAND OF SPECIAL PRIVILEGES NOT FAVORED—While a telephone line was being constructed by a mutual company it became apparent that one wire would be inadequate for the service, and another wire was placed along the same route to the home of one of the subscribers for stock in the company. Both wires were run to his telephone, where a switch belonging to him was installed by which he was enabled to use either wire. The then president of the company testified that he agreed to put in the switch with the understanding that if the board of directors disapproved of it the party should take it out. The board of directors disapproved of it and ordered the switch disconnected. But the party reconnected it and threatened to do so as often as disconnection should be made. In a suit to enjoin the party from thus interfering with the line, the Supreme Court of Nebraska affirms a judgment in the company's favor. The Supreme Court commissioners, who prepared the opinion in the case, say, Red Line Mutual Telephone Company vs. Pharris, 117 Northwestern Reporter, 995, that they cannot see any particular reason why special privilege, if it might be called such, should be given to the defendant. The other patrons of the company paid the same amount as he did and were connected directly with but one line. At most, the contract was that adequate means of communication with the patrons of the company should be given to the defendant. The contract would not permit him perpetually to maintain his switch. Conceding that the contract contemplated but one line, it was not violated by the construction of two wires along the line, even though for convenience the wires were given different names and were connected at a central office when desired. The demoralizing effect of the defendant's maintenance of the switch was not a matter of conjecture, but was apparent from the evidence in the case, as one witness testified that it tended to make the line inefficient, hard feelings, trouble and discord on the line. The proper and businesslike conduct of the affairs of the company seemed to demand that this switch be removed, and with the company's purpose to remove it the courts would not interfere, but, necessity demanding it, would render assistance.

PROPOSALS.

POST OFFICE AT POUGHKEEPSIE, N. Y.—An electric system of a rather elaborate nature has been planned for the United States Post Office at Poughkeepsie, N. Y. Postmaster Sherrill has received the complete specifications from the office of the Supervising Architect at Washington, and is inviting bids for the installation.

POSTOFFICES AT MURFREESBORO, TENN., AND GAINESVILLE, FLA.—The office of the Supervising Architect, Washington, D. C., will receive sealed proposals until January 9 for the construction (complete) of the United States postoffices at Murfreesboro, Tenn., and Gainesville, Fla., in accordance with specifications which may be had at the office of the respective postmasters and at the office of the Supervising Architect.

POST OFFICE AT ANDERSON, S. C.—The office of the Supervising Architect, Washington, D. C., will receive sealed proposals until January 23, for the construction complete (including plumbing, gas piping, heating apparatus, electric conduits and wiring) of the United States Post Office and Court House at Anderson, S. C., in accordance with specifications, which may be obtained from the custodian of site at Anderson or at the office of the Supervising Architect.

DATES AHEAD.

American Roentgen-Ray Society. Annual meeting, New York city, December 28-30.

American Association for the Advancement of Science. Annual meeting, Baltimore, Md., December 28-January 2.

Western Society of Engineers. Next meeting, Chicago, Ill., January 5, 1909.

Chicago Electrical Show. Coliseum, Chicago, Ill., January 16-30, 1909.

Northwestern Electrical Association. Annual meeting, Milwaukee, Wis., January, 1909.

American Association of Electric Motor Manufacturers. Next meeting, January, 1909.

INDUSTRIAL ITEMS.

THE TRUMBULL ELECTRIC MANUFACTURING COMPANY, Plainville, Conn., dresses *Trumbull Cheer* for December in Christmas colors. This issue has some shop notes which will interest.

THE OHIO BRASS COMPANY, Mansfield, Ohio, in a supplement to its general catalogue No. 7, shows new improvements in overhead line material, mine hangers, car equipment, specialties, etc.

THE GREGORY ELECTRIC COMPANY, Chicago, Ill., is distributing a comprehensive bargain sheet of apparatus carried in stock at its works. The list includes everything from miscellaneous supplies to steam engines and alternators.

THE NEW YORK INSULATED WIRE COMPANY, New York, N. Y., has placed on the desks of its friends calendar blotters with a few lines describing the manufacture and advantages of its rubber products for electrical insulation.

F. B. BADT & COMPANY, Monadnock Block, Chicago, electrical engineers and experts, who are the western agents for Weston instruments and Ward Leonard rheostats, have also been appointed western sales agents for "Polar" flaming-arc lamps.

THE ELECTRIC CONTROLLER AND MANUFACTURING COMPANY, Cleveland, Ohio, describes motor-control matters on those pages of its monthly, *Common Sense*, for December, which are not devoted to the epigrammatical writings of David Gibson.

THE NATIONAL BRAKE AND ELECTRIC COMPANY, Milwaukee, Wis., has a handsome illustrated bulletin, No. 386, explaining the advantages and economies of compressed air for industrial service, and describing compressors and controlling apparatus for motor-driven stationary and portable installations.

HARVEY HUBBELL, INCORPORATED, Bridgeport, Conn., has brought out a new ceiling socket equipped with the pull-switch feature, listed as Hubbell ceiling socket No. 35,032. The fixture is designed primarily for the tungsten lamp, and will sustain successfully the weight of the heaviest lamp and shade.

THE BUFFALO FORGE COMPANY, Buffalo, N. Y., describes the Buffalo fan system of heating, ventilating, humidifying and drying, in a handsome book it issues as Catalogue 197. A large part of the book is devoted to some very useful data on the heating and ventilating of public, industrial and other large buildings.

THE AMERICAN CONDUIT MANUFACTURING COMPANY, Pittsburg, Pa., announces that it has completed a large addition to its factory, which is equipped with up-to-date machinery, and is making thorough preparations to manufacture an improved flexible, non-metallic conduit. Patents are being taken out to cover these improvements.

THE MOHAWK ELECTRIC COMPANY, Albany, N. Y., manufacturers of Rollinson electrical specialties, issues a catalogue describing its alternating and direct-current bell ringers, designed to take the place of batteries in providing a low-voltage current supply for the operation of signal apparatus, deriving power from commercial current mains.

THE WORCESTER ELECTRIC MANUFACTURING COMPANY, Worcester, Mass., in its catalogue No. 8 describes its line of knife switches, switchboards, panel boards and fuse blocks for light, power and railway service on both direct and alternating-current circuits. The lists are complete with illustrations, dimensions and prices.

THE NORTHERN ELECTRICAL MANUFACTURING COMPANY, Madison, Wis., devotes its leaflet No. 148 to Northern motors for hoisting service. These motors are compact, simple, rugged and economical. The company's standard spherical motor is described in Bulletin No. 50, and Northern box-type motors are illustrated in Bulletin No. 32.

THE AMERICAN STEAM GAUGE AND VALVE MANUFACTURING COMPANY, 208-220 Camden Street, Boston, Mass., has issued its 1908 illustrated catalogue of gauges, valves, indicators and kindred appliances for governing, indicating, measuring, recording and controlling steam, water, air, gas, oil, ammonia and all other pressures.

THE SPRAGUE ELECTRIC COMPANY, 527-531 West Thirty-fourth Street, New York city, is sending out literature relating to the Sprague electric shovel. The manufacturer declares that this shovel can be used on mono-rails, bridge cranes or gantrys, on stiff-leg derricks, unloading towers, etc. By its use the second man required with a steam rig is entirely dispensed with.

THE J. L. SCHUREMAN COMPANY, Chicago, has prepared a convenient filing form for its bulletin pages, which allows the sheets to be added from time to time following the introduction of new controlling devices. On the pages already available are listed Schureman self-starters, drum-type reversing switches, elevator controllers, pump starters and motor controllers.

THE PACIFIC ELECTRIC HEATING COMPANY, Ontario, Cal., in the November issue of its little monthly, *Hot Points*, announces that the branch office formerly maintained by the company in Chicago has developed into a complete factory, which is located at 63-65 West Washington Street, and invites its customers and friends to call and inspect the plant at their convenience.

THE BUCKEYE ELECTRIC COMPANY, Cleveland, Ohio, is sending to its friends, the central-station operators, some "hard facts" and some interesting data on the saving effected by the use of tungsten lamps on lighting circuits. The moral of the striking folder is to the effect that economy at the illuminant means proportionately greater capacity of a given generating outfit.

THE PETTINGELL-ANDREWS COMPANY, Boston, Mass., has published an interesting article devoted to "The Theft of Current—How to Prevent It, and How to Simplify the Testing of Meters." This article is reproduced in a handsome booklet, and should be of great interest to contractors and central-station operators. Copies will be furnished to those interested upon request.

THE MINNEAPOLIS ELECTRIC EQUIPMENT COMPANY, Minneapolis, Minn., in its "Red Book of Bargains—Everything Electrical," lists a large variety of electrical apparatus actually in stock at the works and ready for immediate shipment. Included in the catalogue are all kinds of motors, generators, transformers, switchboards, electric lighting fixtures and supplies, and measuring instruments.

THE WESTERN ELECTRIC COMPANY, New York city, has issued a price list of "Galvaduct" conduit, couplings and elbows. This product, used in interior conduit work, has an enameled interior which presents a smooth raceway for electrical conductors, and an electro-chemically galvanized exterior which cannot be defaced. "Galvaduct" can be imbedded in concrete without the fear of any injurious effects.

THE GOLD CAR HEATING AND LIGHTING COMPANY, New York city, announces that the interference relating to electric heaters having junction boxes, between an application of James F. McElroy, and the patent granted to Edward E. Gold, No. 850,924, dated April 23, 1907, has been decided by the Patent Office in favor of Edward E. Gold, by reason of an abandonment by McElroy of his claim of priority.

THE FRANKLIN ELECTRIC MANUFACTURING COMPANY, Hartford, Conn., describes "Femco" tungsten and carbon-incandescent lamps and "Femco" reflectors, in bulletin No. 8. To quote the bulletin: "From the Goddess of Liberty guarding the portals of the new world to the greatest floating dry-dock in the world—the Dewey, at Manila—Uncle Sam is using 'Femcos.' There must be a reason. There is, and it's this: The 'Femco' offers a guaranteed uniform quality, prompt delivery and unfailing courtesy."

THE CUTLER-HAMMER MANUFACTURING COMPANY, Milwaukee, Wis., through its Chicago manager, R. M. Van Vleet, advises that owing to the increase in business in both controller and specialty departments, it has been found necessary to secure larger local offices and that two additions have been made to Mr. Van Vleet's force: Horace L. Dawson as an engineering aid, and F. G. Horle as a member of the sales force.

THE K. McLENNAN COMPANY, Chicago, the well-known manufacturers of Gale's commutator compound, report a constantly increasing demand for their products. As is well known this compound is extensively used by dynamo and motor users, not only in the United States, but in almost every portion of the civilized globe. The company will submit samples and full particulars to anyone who may not be familiar with this product.

QUEEN & COMPANY, INC., Philadelphia, Pa., issue a three-leaf folder descriptive of their portable voltmeters and ammeters, the list being complete with code, range of scale, sensibility and price. The instruments listed are of the permanent magnet type, moving coil system, for direct-current only. They are the result of many years' experience in making high-grade scientific and testing instruments. The accuracy of calibration is one-fifth of one per cent.

THE ELECTRIC SUCTION SWEEPER COMPANY, New Berlin, O., is distributing some literature describing and illustrating its electrical suction sweeper. This apparatus is a combined sweeper and vacuum cleaner and is handled as easily as an ordinary carpet-sweeper. Attachments are provided which remove dust or dirt from under stationary or heavy articles, and also from elevated objects, such as pictures, moldings, wall coverings and upholstered furniture.

THE ELECTRIC GOODS MANUFACTURING COMPANY, Boston, Mass., has issued a telephone section of its nineteenth edition catalogue, in which it describes and illustrates the extensive and practical line of telephone apparatus of its manufacture. The convenient styles of equipment admit a wide range of choice and meet many special needs. This catalogue is especially arranged to help the architect and contractor in the work of specifying and ordering, related subjects being near at hand.

THE HORNBERGER TRANSFORMER COMPANY, Lafayette, Ind., has prepared a bulletin and price list of its standard lighting transformers, which are made up to sizes with a capacity of 200 kilowatts. Silicon-alloy steel is exclusively used in the manufacture of the modified type of these apparatus. As this improved steel was used in these transformers almost two years ago, the manufacturers feel that their pioneer experience with the material has been of great service in securing refinement of design.

THE UNION ELECTRIC LIGHT AND POWER COMPANY, St. Louis, Mo., has prepared a really handsome bulletin to be sent to its local customers, describing and illustrating in detail the varied line of electrical heating devices that are now on the market. Specifications and price are given in each case. The company maintains a continuous electrical exhibition of these devices at its show rooms, Tenth and St. Charles Streets, and also offers customers a free trial of any piece of apparatus in their homes.

GEORGE W. JACKSON, INC., Chicago, has brought out a souvenir booklet of its disposal station department that is of unusual typographical excellence and technical and popular interest. The methods of carrying off city waste, excavation spoil, refuse and snow from the congested downtown district of Chicago by means of the freight tunnel system and river scows are described and illustrated and will prove an absorbing chapter for one who is interested in the great and peculiar problems undertaken by this corporation.

THE FORT WAYNE ELECTRIC WORKS, Fort Wayne, Ind., has compiled a practical guide for transformer testing which is simply written and diagrammed so as to be of service to the practical central-station operator. The guide contains accurate directions for making the usual insulation, copper-loss, core-loss, impedance, ratio, polarity, heat and regulation tests, as well as an amount of useful data in connection with these determinations. Bulletin No. 1109 illustrates the line of engine-driven multiphase alternators manufactured by the Fort Wayne Electric Works.

THE AMERICAN BOILER ECONOMY COMPANY, North American Building, Philadelphia, has prepared a handsomely executed treatise describing the Copes boiler-feed regulator. In turn, the several advantages to be gained by automatic regulation are taken up, such as protection to the boiler, protection to the engine or turbine, saving of cylinder oil, lessened friction and wear in the engine, higher efficiency of super-heaters, higher efficiency of engines and turbines, and greater economy from exhaust steam feed-water heaters and fuel economizers. The engineering considerations of these points are brought out fully, bull's-eye charts from recording thermometers being shown, for instance, to demonstrate the fuel-saving realized by holding the feed always equal to the evaporation. In addition there are numerous illustrations showing installations of Copes regulators, also the manner of operation and construction of the regulator and of the Copes pump governor employed to insure a constant excess of pressure in the feed line. This appliance is especially valuable in large plants where the water level must be maintained in a great number of boilers and should be of interest to consulting, designing and managing engineers.

THE COMMONWEALTH EDISON COMPANY, Chicago, maintains its repair shops at 76 Market Street, which are said to be one of the largest and best-equipped repair shops in the world. The company is in a position to handle any kind of repair work, whether mechanical or electrical. The completeness of the equipment, it is stated, guarantees lowest costs, while the facilities for turning out work quickly are exceptonal. Temporary motors will be installed, when required, so that the service will not be interrupted. Repair work of any kind will be called for and delivered without extra charge.

J. B. TAYLOR & COMPANY, New York, have been incorporated under the laws of the state of Delaware, with a capital stock of $500,000, for the purpose of entering the field of engineering, construction, reorganization and the financing of street railway, steam railroads, water works, gas, electric light and organization propositions. The company has offices in the Hudson Terminal Building. Taylor & Company have already secured a contract to build the Sanoody Valley Railroad, connecting with the Mobile & Ohio Railroad at Sucarnochee, Miss., and are organizing a capable engineering and construction force.

THE STANDARD ROLLER BEARING COMPANY, Philadelphia, Pa., is distributing an illuminative list of the extensive floor spaces occupied by its various departments. The company believes that its broad experience in supplying over a million bearings of various types, for all classes of work, has resulted in the accumulation of much data of inestimable value, from which it is enabled to design bearings for all loads and speeds. Manufacturing over fifty types of ball and roller bearings, all having their proper uses, the company is naturally well equipped to recommend the proper bearing for any specific condition or purpose.

THE JOSEPH DIXON CRUCIBLE COMPANY, Jersey City, N. J., in the December number of *Graphite* illustrates the use of graphite points on lighting rods protecting tall chimneys. The tip is made with a pointed graphite pencil, one inch in diameter and five inches in length, set into a cap to fit standard pipe. A hole drilled part way up the axis of the graphite rod receives the copper conductor cable, which is held in place by a set-screw. The Alphons Custodis Chimney Construction Company, which has been using these tips, reports that not a single chimney thus protected has been damaged by lightning, although there are numerous records of similar but unprotected structures sustaining severe injury.

THE CENTRAL ELECTRIC COMPANY, Chicago, is distributing a circular on "Combat" ignition batteries for automobile and gas-engine service. The circular contains a full description of the battery construction, and also gives directions for charging from the regular lighting circuits. It is asserted that corrosion at the binding posts is made impossible by the arrangement of the terminals. The company is also distributing several new fliers on condulet and box receptacles to fit the various makes of boxes now on the market. In the new design it is declared that the amount of breakage is minimized and furthermore that the contacts are of capacity to withstand extremely heavy overloads.

THE AMERICAN BATTERY COMPANY, Chicago, Ill., has published a sixteen-page booklet describing American electrolytic rectifiers. The construction, use and maintenance of the rectifiers are subjects treated at length in several pages. American rectifiers are made in a variety of styles and sizes designed to meet the demand for a low-price converter for making use of an alternating-current supply for the charging of storage batteries of from one to fifty cells of any capacity up to 300 ampere-hours. They may be profitably used in the charging of storage batteries of the ignition type for electric vehicles, storage batteries for dentists' and physicians' use, for telephone, telegraph and signal work, and for many other applications.

THE GENERAL ELECTRIC COMPANY, Schenectady, N. Y., in bulletin No. 4630 lists and describes its direct-current portable type DP instruments, which have been designed for laboratory and general testing purposes. These instruments are constructed to be well protected from mechanical injury and from the effect of stray fields. The indications of the pointer are rendered dead-beat. This line of instruments comprises ammeters, voltmeters, milammeters and millivoltmeters. General Electric bulletin No. 4629 is devoted to automobile accessories manufactured by the company. The apparatus illustrated consists of charging panels of various types, automobile instruments and incandescent lamps, motor-generator sets, automobile motors and controllers, battery-charging rheostats, low-tension magnetos, air-compressor outfits, etc.

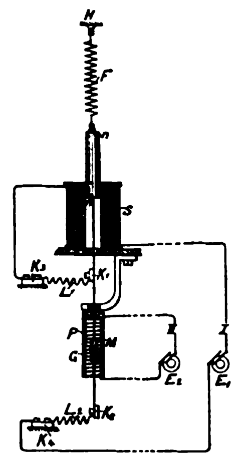
RECORD OF ELECTRICAL PATENTS.

Issued (United States Patent Office) December 15, 1908.

906,509. ELECTRIC WATER VALVE. George P. Carroll, Bridgeport, Conn. Filed March 25, 1907. The port is automatically held open by an electromagnet when power is on the line.

906,513. TELEPHONE SYSTEM. William W. Dean, Chicago, Ill., assignor to Kellogg Switchboard and Supply Company, Chicago, Ill. Filed November 11, 1903. Relates to a special arrangement of supervisory and cut-off relays.

906,523. SELECTIVE MECHANICAL OPERATOR. Edwin R. Gill, Yonkers, N. Y. Filed March 12, 1906. A machine element intended to be brought to a predetermined position has a main impelling device adapted to move step by step by means of a magnet and its armature.



906,550.—NERNST LAMP.

906,550. ELECTRICAL INCANDESCENT LAMP. Walther Nernst, Göttingen, Germany, assignor to Nernst Lamp Company, Pittsburg, Pa. Filed October 20, 1897. The heating coil for a Nernst lamp is described.

906,556. VULCANIZER. Frank C. Perkins, Buffalo, N. Y., assignor of one-half to Ferdinand E. Finsterbach, Buffalo, N. Y. Filed October 9, 1907. A heating chamber has a removable wall with inner and outer sockets secured to it, the inner socket receiving an incandescent lamp and the outer socket a plug for the feed wires.

906,576. ELECTRIC CONTROLLER. Clarence L. Taylor, Alliance, Ohio, assignor to The Morgan Engineering Company, Alliance, Ohio. Filed February 21, 1908. In combination with a casing containing oil is a contact drum, a set of contact fingers and operating mechanism, all supported by and removable with the hinged cover.

906,582. AUTOMATIC TRAIN STOPPER. Charles D. Tisdale, Randolph, Mass.; Frank L. Tisdale, administrator of said Charles D. Tisdale, deceased. Filed May 16, 1907. A locomotive has a brush fixed to its pilot and adapted to engage a fixed track contact, a battery being grounded on the wheels and an electric motor adapted to operate the air-brake valve.

906,599. MAGNET SHIELD. Charles E. F. Ahlm, Cleveland, Ohio, assignor to Electric Controller and Supply Company. Filed January 13, 1908. A lifting magnet with an inner and an outer pole has a magnetizing winding between the poles and an annular shield for retaining the winding.

906,602. PRIVATE-BRANCH-EXCHANGE TELEPHONE SYSTEM. Frank Arens, Cincinnati, Ohio. Filed December 28, 1907. In combination with the cord mains is a shunt circuit controlled by the relays.

906,615. REPAIRING AND TESTING MEANS FOR CONTACTLESS THERMAL PROTECTORS. Frank B. Cook, Chicago, Ill. Filed July 28, 1905. A repairing tool comprises a handle, a metallic contact strip and a lever pivoted on an insulating support and provided with a thumb-piece adapted to be depressed.

906,618. PERFORATOR FOR PREPARING TELEGRAPHIC TRANSMITTING TAPES. Patrick B. Delany, South Orange, N. J., assignor to The Telepost Company of Maine, Augusta, Me. Filed April 16, 1902. An electromagnetic perforator consists of a key, a pole-changer magnet controlled thereby, a differentially-wound polarized relay and punch magnets controlled by the relay and pole changer.

906,636. RAILWAY SAFETY SYSTEM. Janko Kovacevic, Youngstown, Ohio. Filed October 14, 1907. The railway is equipped with three parallel contact strips controlling a signal on the locomotive.

906,649. SHOAL-WATER ALARM. Patrick McCarthy, Cleveland, Ohio. Filed June 1, 1908. The ship carries a drag cable with an inclined blade at its free end and an electric alarm to indicate when the device is in contact with the bottom.

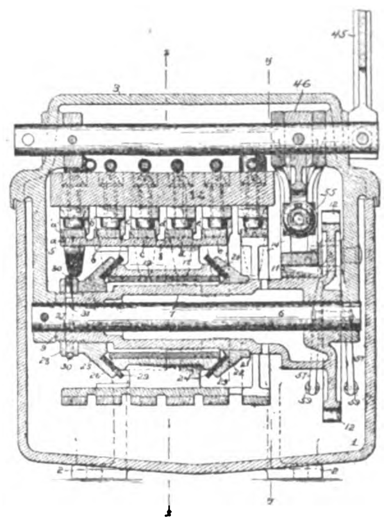
906,659. COMBINATION PUMP AND COMPRESSOR SYSTEM. Walter J. Richards, Milwaukee, Wis., assignor to The National Brake and Electric Company, Milwaukee, Wis. Filed July 9, 1908. A motor drives either one of two pumps through a pair of magnetic clutches.

906,669. ELECTROLYTIC APPARATUS FOR USE IN THE MANUFACTURE OF BLEACHING LIQUORS. Alfred Vogelsang, Dresden, Germany. Filed March 5, 1907. A number of compartments are situated one above another in a stair-like manner, an electrode between two successive compartments extending upwardly and forming a wall for the compartment next above it.

906,682. ELECTRIC FURNACE. Kristian Birkeland, Christiania, Norway. Filed January 5, 1907. A long electric furnace has distanced electrodes to produce a long arc and electromagnetic means to distort the arc into a helix.

906,726. APPARATUS FOR DETINNING TIN SCRAP. Meredith Leitch, Elizabeth, N. J., assignor to Metal Process Company. Filed February 28, 1907. In combination with a stationary cathode and an anode is a tank for the electrolyte and a hydraulic plunger for lowering and raising it.

906,729. IGNITION TIMER FOR INTERNAL-COMBUSTION ENGINES. Francis C. Mason and Guy L. Sintz, Grand Rapids, Mich., assignors to Norman W. Chamberlin, Grand Rapids, Mich. Filed October 26, 1906. A rotative shaft carries a tubular head and a yoke with a contact.



906,576.—ELECTRIC CONTROLLER.

906,738. SNAP-SWITCH. Johann G. Peterson, Hartford, Conn., assignor to The Arrow Electric Company, Hartford, Conn. Filed April 10, 1908. The actuating mechanism has a pole-carrying plate with integral arms upturned from diametrically opposite edges and perforated pole plates slipped upon the arms.

906,739. ELECTRIC-SWITCH RECEPTACLE. Johann G. Peterson, Hartford, Conn., assignor to The Arrow Electric Company, Hartford, Conn. Filed September 16, 1908. Describes the construction and method of mounting the cover for the receptacle.

906,740. PUSH-BUTTON ELECTRIC SWITCH. Johann G. Peterson, Hartford, Conn. Assignor to the Arrow Electric Company, Hartford, Conn. Filed September 16, 1908. A two-button oscillating switch.

906,749. APPARATUS FOR OPERATING WINDOWS. Wilson B. Strong, Easthampton, Mass. Filed December 5, 1907. Comprises two electric motors with a winding drum secured upon each shaft, a cord wound upon each drum and adapted for connection with each sash.

906,762. PUSH-BUTTON. Henry Wilhelm, New York, N. Y. Filed November 30, 1907. The button passes through a cap that fits over a cup.

906,787. INSULATOR PIN. Charles G. Ette, St. Louis, Mo., assignor to Ette Investment Company, St. Louis, Mo. Filed May 4, 1908. A metallic pin is provided at its lower end with an integral tongue that is adapted to be bent into engagement with the cross-arm.

906,799 and 906,800. LOCK AND BLOCK-SIGNAL SYSTEM. Robert J. Hewett, Westfield, N. J., assignor to The Hall Signal Company. Filed January 10, 1908. A circuit connecting signaling stations has circuit-breakers interposed in it and controlled by the traffic and means acting automatically to lock a manual controlling member and transmit a relese when the circuit has been closed.

906,861. ELECTRICAL BLOCK-SIGNALING SYSTEM FOR RAILWAYS. George H. Brown, Belfast, Ireland. Filed September 20, 1907. There are in combination conductors on the track, audible and visible electrical signaling devices on the engine and similar devices in each signal cabin.

906,926 and 906,927. ELECTRICAL APPARATUS FOR TIMING CLOCKS AND WATCHES. Wilson E. Porter, New Haven, Conn., assignor to New Haven Clock Company, New Haven, Conn. Filed April 27, 1908. A timing mechanism is located in an electric circuit and provided with a rated pointer driven in unison with the master clock.

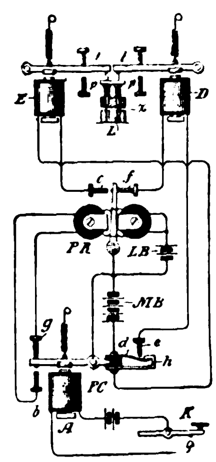
906,928. METHOD OF MAKING DYNAMO BRUSHES. Georg Preuss, Charlottenburg, Germany. Filed July 31, 1906. Pure graphite is moistened with nitric acid and afterward heated, the graphite forms resulting being provided electrically with a metal coating and then formed and pressed into brushes.

906,939. ELECTRICALLY-OPERATED GUN CONTROL. James B. Ryan, Hoboken, N. J., assignor to Stephen A. Farrell, Brooklyn, N. Y. Filed February 3, 1908. There are means controllable by the undesirable motions of a vessel for reversing the motor and another mechanism similarly controlled for varying the energy supplied to the motor.

906,984. RETRIEVING MECHANISM FOR TROLLEY POLES. Martin L. Addington, Indianapolis, Ind., assignor of one-third to John E. Hafner, Indianapolis, Ind. Filed March 3, 1908. A rotary drum has separate cords attached thereto to simultaneously wind and unwind respectively and an automatically actuated motor connected with one of the cords.

906,990. ELECTRICAL HEATING APPARATUS. Clifford D. Babcock, New York, N. Y., assignor to United Wireless Telegraph Company, New York, N. Y. Filed July 24, 1907. Comprises a number of bare uninsulated coils arranged one above the other in a vessel.

906,991. OSCILLATION DETECTOR. Clifford D. Babcock, New York, N. Y., assignor to United Wireless Telegraph Company, New York, N. Y. Filed October 2, 1907. Consists of a thermo-electric couple and a local circuit in combination with means for converting the energy of the oscillations into heat and thereby elevating the temperature of the couple.



906,618.—ELECTROMAGNETIC TELEGRAPHIC-TAPE PERFORATOR.

906,994. TROLLEY. Frederick C. Bauer, Sr., and Frederick C. Bauer, Jr., Camden, N. J. Filed May 1, 1908. The wheel has a central groove with deep spiral grooves on either side.

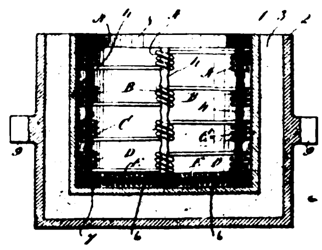
907,002. SPARK PLUG. Henry L. Brownback, Norristown, Pa. Filed January 15, 1908. A shell is formed with a fixed arm projecting within and a number of sparking points projecting in opposite directions from the terminus of the arms.

907,061. METHOD OF DETINNING TIN SCRAP. Meredith Leitch, Springfield, Mass., assignor to Metal Process Company, New York, N. Y. Original application filed February 28, 1907. Divided and this application filed September 19, 1908. The method consists in drawing [redacted]lyte out of the bath from beneath the surface and returning it to the bath at a point below the surface.

907,062. TELEPHONE DROP. Tiodolf Lidberg, Chicago, Ill., assignor to Swedish-American Telephone Company, Chicago, Ill. Filed November 26, 1906. An armature and latching mechanism is secured to the stationary part and a removable electromagnet is arranged for insertion or withdrawal relative to the support.

907,083. RAIL BOND. Edwin H. McHenry, New Haven, Conn., assignor of one-fourth to Charles H. Morrison, New Haven, Conn. Filed March 16, 1908. Consists of a spring steel core provided with a coating of copper.

907,088. ELECTRIC TIME-SWITCH. Ole P. Noisom and Carl J. Lindewald, South Bend, Ind.; said Lindewald assignor of one-half to said Noisom. Filed January 27, 1908. Comprises a switching element movable in a circular path with a step-by-step movement.



906,990.—ELECTRIC HEATER.

907,098. PUSH-BUTTON SWITCH. George B. Thomas, Bridgeport, Conn., assignor to The Perkins Electric Switch Manufacturing Company, Bridgeport, Conn. Filed June 5, 1908. A switch has two push-buttons and an oscillating operating lever with connecting links pendent from ends thereof.

907,106. THREE-POSITION MOTOR SIGNAL. Clarence W. Coleman, Westfield, N. J., assignor to The Hall Signal Company. Filed September 27, 1907. Electrically-operated locking and releasing means consist of a step pivotally mounted on the signal actuating member.

907,108. INSULATOR FOR CIRCUIT-BREAKERS. Leonard L. Elden, Dorchester, Mass., assignor to Sears B. Condit, Jr., Boston, Mass. Original application filed June 20, 1901. Divided and this application filed December 2, 1903. An oil switch has an oil well removably suspended in position to submerge the electrodes in all their operative movements.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired December 22, 1908:

465,444. ELECTRIC SWITCH. H. Barton, London, England.

465,469. ELECTRIC-RAILWAY TROLLEY. C. S. Foster, Whitesborough, N. Y.

465,511. ELECTRIC SNAP SWITCH. Wm. S. Andrews, New York, N. Y.

465,512. RHEOSTAT. W. S. Andrews and A. K. Warren, New York, N. Y.

465,514. ELECTRIC ARC LAMP. H. P. Ball, Brooklyn, N. Y.

465,525. ELECTROLYTIC APPARATUS FOR TREATING METALS. E. S. Hayden, Waterbury, Conn.

465,592. GEARING FOR ELECTRIC MOTOR CARS. O. F. Evans, Columbus, Ohio.

465,594. SYSTEM OF ELECTRICAL DISTRIBUTION. F. O. La Roche, Philadelphia, Pa.

465,602. ELECTRIC CIRCUIT-CLOSER FOR BURGLAR ALARMS. Wm. C. Thompson, Minneapolis, Minn.

465,613. ELECTRIC RAILWAY. Wm. H. Applegate, Atlantic, Iowa.

465,618. ELECTRIC SWITCH. G. E. Painter, Baltimore, Md.

465,648. COMBINED SIGNAL AND TELEPHONE SYSTEM. T. W. O'Brien, Wilkes-Barre, Pa.

465,685. ELECTRIC ARC LAMP. H. C. Waldecker, Austin, Minn.

465,805. MEANS FOR TURNING ON AND OFF ELECTRIC CURRENTS. T. C. Smith and B. D. Acker, Philadelphia, Pa.

465,806. ELECTRIC-RAILWAY TROLLEY. F. J. Sprague and P. F. O'Shaughnessy, New York, N. Y.

465,808. DYNAMO-ELECTRIC MACHINE. R. Thury, Geneva, Switzerland.

465,809. ELECTRICAL TESTING INSTRUMENT. R. Varley, Jr., Englewood, N. J.

POSITIONS WANTED

The rate for "Positions Wanted" advertisements of forty words or less is one dollar an insertion; additional words two cents each, payable in advance. Remittances and copy should reach this office not later than Monday, 12 o'clock noon, for the next succeeding issue.

Replies may be sent in care of Electrical Review and Western Electrician, 507 Marquette Building, Chicago, or 13-21 Park Row, New York.

POSITION WANTED—As chief engineer in electric-lighting and power plant up to 5,000 horsepower, or superintendent of smaller plant; can refer to the best men in the steam and mechanical engineering field; 36 years old, married; don't drink; steam turbine experience; a money saver and can prove it. Wm. Westerfield, Box 764, Lincoln, Neb.

POSITION WANTED—Technical graduate with large experience in installing and maintenance wants position as manager of lighting or street-railway plant in city of not less than 15,000. Best references. A business getter. Box 1036, care of Electrical Review and Western Electrician, Chicago.

HELP WANTED

The rate for "Help Wanted" advertisements of forty words or less is one dollar and fifty cents an insertion; additional words three cents each, payable in advance. Remittances and copy should reach this office not later than Monday, 12 o'clock noon, for the next succeeding issue.

Replies may be sent in care of Electrical Review and Western Electrician, 507 Marquette Building, Chicago, or 13-21 Park Row, New York.

WANTED—A thoroughly competent electrician by a modern electric light and power plant, 1,000 kilowatts capacity, in southern city. Want a thorough and practical worker, familiar with every detail of line construction and inside and outside wiring. Must be able and willing to supervise, also do work, and able to take care of transformers, meters, motors and arc lamps, and see that customers' service and all lines and properties of the company outside of power house are kept in first-class condition. Must be reliable and of good character and habits. Good opportunity for advancement for right man. Give experience and references. Address No. 1031, care of Electrical Review and Western Electrician, Chicago.

WANTED— Inspection engineer, to take charge of men in inspection and testing of the product of the shop of a direct-current dynamo and motor factory. Must be well educated, experienced and capable of instructing. Address Box 1033, care of Electrical Review and Western Electrician, Chicago.

PROPOSALS

The rate for "Proposal" advertisements is 15 cents per line, payable in advance. Remittances and copy should reach this office not later than Monday, 12 o'clock noon, for the next succeeding issue.

APPLICATION FOR BIDS TO LIGHT THE CITY OF OLNEY—Sealed bids will be received up to noon, Tuesday, January 12, 1909, for furnishing the city of Olney, Ill., with fourteen or more arc lights of 2,000-candlepower each and 114 or more incandescents, 40-candlepower each, for a period of ten years. Also for supplying commercial and resident lighting for the inhabitants of the city.

The bidder whose bid is accepted, to receive a ten-year franchise.

Successful bidder to furnish a good and sufficient bond in the sum of $5,000 for the faithful compliance with the terms of the contract within nine months from the time the contract is let.

The city reserves the right to reject any and all bids.

Bids to be mailed to:

Phil K. Wilson, mayor, or N. L. Crout, or S. C. Wilson, Olney Ill., Fire and Light Committee.

MISCELLANEOUS

The rate for "Miscellaneous" advertisements of forty words or less is one dollar and fifty cents an insertion; additional words three cents each, payable in advance. Remittances and copy should reach this office not later than Monday, 12 o'clock noon, for the next succeeding issue.

Replies may be sent in care of Electrical Review and Western Electrician, 507 Marquette Building, Chicago, or 13-21 Park Row, New York.

WANTED TO LEASE—(By a successful manager) A central station plant in a good town of 2,000 to 10,000 population, located somewhere in this great Mississippi valley. Will lease for a long term or will manage same on salary. Address 1035, care of Electrical Review and Western Electrician, Chicago, Ill.

ELECTRICAL MECHANICAL CONSULTING

DIRECTORY OF ENGINEERS

CONTRACTORS SPECIAL INTERESTS

THE JOHN F. KELLY ENGINEERING CO.
CONSULTING AND CONTRACTING ENGINEER
149 BROADWAY NEW YORK
Phone — 7259 Cortlandt

LAMAR LYNDON
CONSULTING ELECTRICAL ENGINEER
Long Distance Power Transmission and Alternating Current problems a specialty.
2 Rector Street, NEW YORK

New England Engineering Co.
100 Broadway NEW YORK
WATERBURY, CONN.
Electric Railways, Electric Light and Power Plants, Gas and Waterworks, or any other engineering installations built or remodeled.

RUEBEL & WELLS
CONSULTING MECHANICAL and ELECTRICAL ENGINEERS
Suite 301 Chemical Building
ST. LOUIS, U. S. A.

EDWARD H. KITFIELD
MECHANICAL ENGINEER
53 State Street BOSTON
Electric Lighting and Street Railway Power Stations and Buildings

Telephone 6925 Cortlandt
ALBERT J. MARSHALL
CONSULTING ILLUMINATING ENGINEER
Glackner Building NEW YORK

CHARLES L. PILLSBURY
CONSULTING MECHANICAL and ELECTRICAL ENGINEER
Consulting Engineer to Minnesota State Board of Control
Suite 206, Metropolitan Life Bldg.
MINNEAPOLIS, MINN.

Frederick Sargent A. D. Lundy
SARGENT & LUNDY
ENGINEERS
RAILWAY EXCHANGE
Cor. Jackson and Michigan Boulevards
CHICAGO

EDWARD R. KNOWLES
ELECTRICAL, CIVIL AND MECHANICAL ENGINEER
CONSULTING EXPERT
Industrial Engineering in all its branches. Remodeling Power, Light and Heat Installations. Gas Engine and Producer Power Systems.
PULITZER BLDG. NEW YORK

RALPH D. MERSHON
CONSULTING ELECTRICAL AND MECHANICAL ENGINEER
Estimates, Reports, Plans, Specifications and Supervision of Electric Lighting, Railway and Power Plants.
Long Distance Power Transmission
NEW YORK: 60 Wall Street
MONTREAL: Street Railway Chambers

JOHN A. RADFORD
ENGINEER
Plans, Specifications, Reports, Tests, Estimates and Supervision for Complete Steam and Electrical Installations.
1325-1326 Marquette Building
CHICAGO, ILL.

W. H. SCHOTT
ENGINEER
1100 to 1128 American Trust Bldg.
CHICAGO
Designer and Builder — Central Station Heating, Gas, Electric Light, Water Works and Power Plants.

KOHLER BROS.
CONTRACTING ELECTRICAL ENGINEERS
Lighting—Power—Railways
1804-1806-1808-1810-1812 Fisher Bldg.
CHICAGO

Samuel G. McMeen Kempster B. Miller
McMEEN & MILLER
TELEPHONE ENGINEERS
Complete Plans, Special Reports, Laboratory Certificates, Telephone Patents Solicited
1454 to 1457 Monadnock Block
CHICAGO, ILLINOIS

WARREN B. REED
CONSULTING ENGINEER
Lighting Plants, Power Plants, Street Railroads, Wiring Plans and Specifications, Estimates, Inspection, Supervision.
1013 Hibernia Bank Building
Long Distance Phone Main 878
NEW ORLEANS, U. S. A.

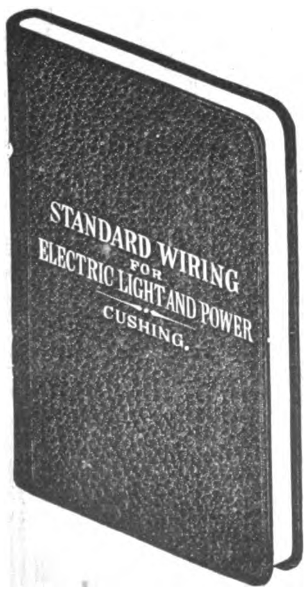
ENGINEERS

whose names appear in this department may be sure that their addresses are in the most conspicuous location for the electrical industry.

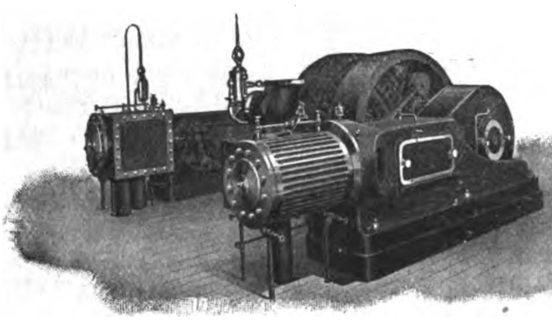


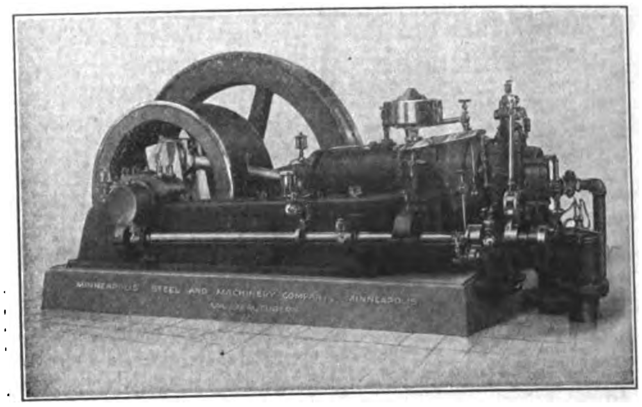
OVER 150,000 SOLD

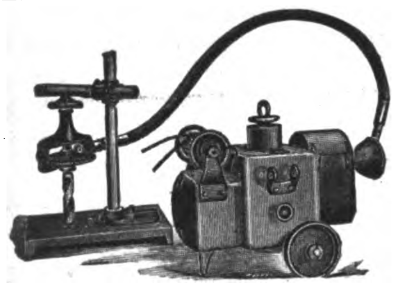
THERE is only one book on Electric Light and Power Wiring and Construction that is kept absolutely accurate and up to date. Every Insurance and City Inspector knows it and will pass your work if done in accordance with "STANDARD WIRING."

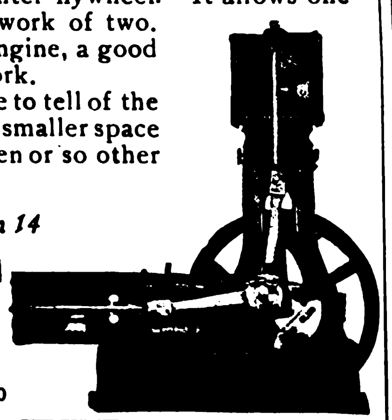
MAILED FOR $1.00

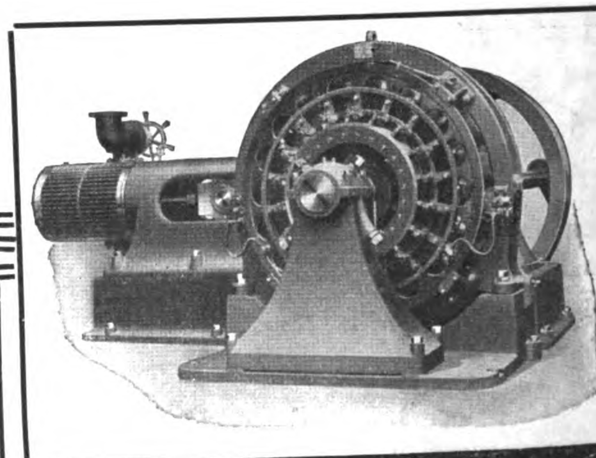
Electrical Review Publishing Co., Marquette Bldg., Chicago







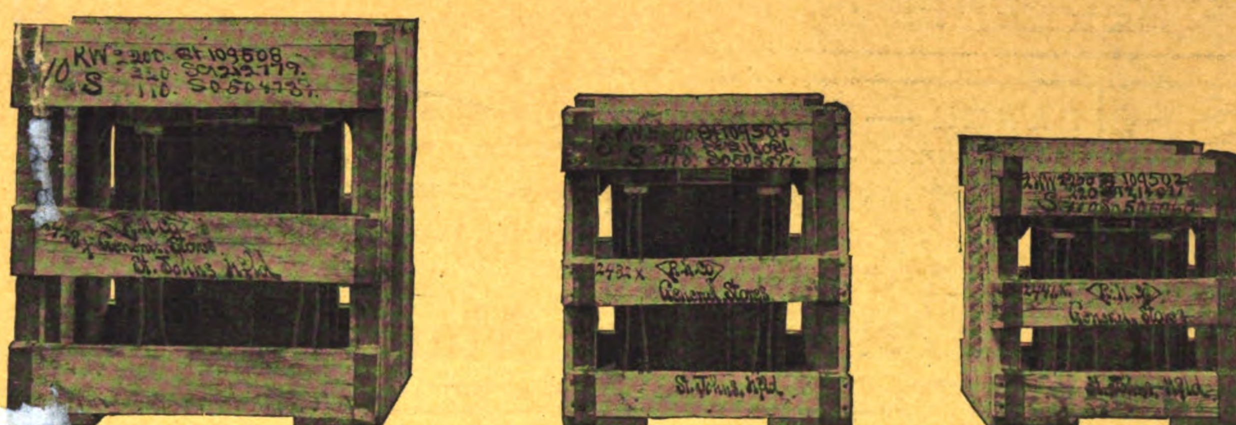




WESTINGHOUSE

New Shell Type "S" Distributing Transformers

16 Capacities, ½ to 50 Kilowatt.—50 to 140 Cycles
Primary: 1100-220 Volts. Secondary: 110-220 and 220-440 Volts



The Packing Cases

are so designed that Type "S" Transformers may be inspected and tested without removing them from the cases. All terminals are within easy reach. Central-station men will appreciate the convenience of this arrangement.

Type "S" Transformers are fully illustrated and described in Circular 1057.
Ask nearest office for proposition and specifications.
